- With standard SQL, when you drop a table, all privileges for the table are revoked. With standard SQL, when you revoke a privilege, all privileges that were granted based on the privilege are also revoked. In MySQL, privileges can be dropped only with explicit `REVOKE` statements or by manipulating the MySQL grant tables.
- In MySQL, if you have the `INSERT` privilege on only some of the columns in a table, you can execute `INSERT` statements on the table; the columns for which you don't have the `INSERT` privilege are set to their default values. Standard SQL requires you to have the `INSERT` privilege on all columns.

13.5.1.4. `RENAME USER` Syntax

```
RENAME USER old_user TO new_user
      [, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. To use it, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database. An error occurs if any old account does not exist or any new account exists. The *old_user* and *new_user* values are given the same way as for the `GRANT` statement.

The `RENAME USER` statement was added in MySQL 5.0.2.

13.5.1.5. `SET PASSWORD` Syntax

```
SET PASSWORD = PASSWORD('some password')
SET PASSWORD FOR user = PASSWORD('some password')
```

The `SET PASSWORD` statement assigns a password to an existing MySQL user account.

The first syntax sets the password for the current user. Any client that has connected to the server using a non-anonymous account can change the password for that account.

The second syntax sets the password for a specific account on the current server host. Only clients with the `UPDATE` privilege for the `mysql` database can do this. The *user* value should be given in *user_name@host_name* format, where *user_name* and *host_name* are exactly as they are listed in the `User` and `Host` columns of the `mysql.user` table entry. For example, if you had an entry with `User` and `Host` column values of 'bob' and '%.loc.gov', you would write the statement like this:

```
mysql> SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass');
```

That is equivalent to the following statements:

```
mysql> UPDATE mysql.user SET Password=PASSWORD('newpass')
-> WHERE User='bob' AND Host='%.loc.gov';
mysql> FLUSH PRIVILEGES;
```

Note: If you are connecting to a MySQL 4.1 or later server using a pre-4.1 client program, do not use the preceding `SET PASSWORD` or `UPDATE` statement without reading Section 5.6.9, “Password Hashing in MySQL 4.1” first. The password format changed in MySQL 4.1, and under certain circumstances it is possible that if you change your password, you might not be able to connect to the server afterward.

Starting from MySQL 4.1, you can check what your current authentication *user@host* entry is by

executing `SELECT CURRENT_USER()`.

13.5.2. Table Maintenance Statements

13.5.2.1. ANALYZE TABLE Syntax

```
ANALYZE [LOCAL | NO_WRITE_TO_BINLOG] TABLE tbl_name [, tbl_name] ...
```

This statement analyzes and stores the key distribution for a table. During the analysis, the table is locked with a read lock. This works on MyISAM and BDB tables and (as of MySQL 4.0.13) InnoDB tables. For MyISAM tables, this statement is equivalent to using `myisamchk -a`.

MySQL uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant.

The statement returns a table with the following columns:

Column	Value
Table	The table name
Op	Always analyze
Msg_type	One of status, error, info, or warning
Msg_text	The message

You can check the stored key distribution with the `SHOW INDEX` statement. See Section 13.5.4.11, “`SHOW INDEX` Syntax”.

If the table hasn't changed since the last `ANALYZE TABLE` statement, the table is not analyzed again.

Before MySQL 4.1.1, `ANALYZE TABLE` statements are not written to the binary log. As of MySQL 4.1.1, they are written to the binary log unless the optional `NO_WRITE_TO_BINLOG` keyword (or its alias `LOCAL`) is used.

13.5.2.2. BACKUP TABLE Syntax

```
BACKUP TABLE tbl_name [, tbl_name] ... TO '/path/to/backup/directory'
```

Note: This statement is deprecated. We are working on a better replacement for it that will provide online backup capabilities. In the meantime, the `mysqlhotcopy` script can be used instead.

`BACKUP TABLE` copies to the backup directory the minimum number of table files needed to restore the table, after flushing any buffered changes to disk. The statement works only for MyISAM tables. It copies the `.frm` definition and `.MYD` data files. The `.MYI` index file can be rebuilt from those two files. The directory should be specified as a full pathname.

Before using this statement, please see Section 5.8.1, “Database Backups”.

During the backup, a read lock is held for each table, one at a time, as they are being backed up. If you want to back up several tables as a snapshot (preventing any of them from being changed during the backup operation), you must first issue a `LOCK TABLES` statement to obtain a read lock for every table in the group.

The statement returns a table with the following columns:

Column	Value
Table	The table name
Op	Always backup

Msg_type	One of status, error, info, or warning
Msg_text	The message

BACKUP TABLE is available in MySQL 3.23.25 and later.

13.5.2.3. CHECK TABLE Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
```

```
option = {QUICK | FAST | MEDIUM | EXTENDED | CHANGED}
```

Checks a table or tables for errors. CHECK TABLE works for MyISAM and InnoDB tables. For MyISAM tables, the key statistics are updated.

As of MySQL 5.0.2, CHECK TABLE also can check views for problems, such as tables that are referenced in the view definition that no longer exist.

The CHECK TABLE statement returns a table with the following columns:

Column	Value
Table	The table name
Op	Always check
Msg_type	One of status, error, info, or warning
Msg_text	The message

Note that the statement might produce many rows of information for each checked table. The last row has a Msg_type value of status and the Msg_text normally should be OK. If you don't get OK, or Table is already up to date you should normally run a repair of the table. See Section 5.8.3, "Table Maintenance and Crash Recovery". Table is already up to date means that the storage engine for the table indicated that there was no need to check the table.

The different check options that can be given are shown in the following table. These options apply only to checking MyISAM tables and are ignored for InnoDB tables and views.

Type	Meaning
QUICK	Don't scan the rows to check for incorrect links.
FAST	Only check tables that haven't been closed properly.
CHANGED	Only check tables that have been changed since the last check or haven't been closed properly.
MEDIUM	Scan rows to verify that deleted links are okay. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys.
EXTENDED	Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time!

If none of the options QUICK, MEDIUM, or EXTENDED are specified, the default check type for dynamic-format MyISAM tables is MEDIUM. This is the same thing as running **myisamchk -medium-check *tbl_name*** on the table. The default check type also is MEDIUM for static-format MyISAM tables, unless CHANGED or FAST is specified. In that case, the default is QUICK. The row scan is skipped for CHANGED and FAST because the rows are very seldom corrupted.

You can combine check options, as in the following example, which does a quick check on the table to see whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

Note: In some cases, `CHECK TABLE` changes the table. This happens if the table is marked as ``corrupted" or ``not closed properly" but `CHECK TABLE` doesn't find any problems in the table. In this case, `CHECK TABLE` marks the table as okay.

If a table is corrupted, it's most likely that the problem is in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

If you just want to check a table that you assume is okay, you should use no check options or the `QUICK` option. The latter should be used when you are in a hurry and can take the very small risk that `QUICK` doesn't find an error in the data file. (In most cases, MySQL should find, under normal usage, any error in the data file. If this happens, the table is marked as ``corrupted" and cannot be used until it's repaired.)

`FAST` and `CHANGED` are mostly intended to be used from a script (for example, to be executed from **cron**) if you want to check your table from time to time. In most cases, `FAST` is to be preferred over `CHANGED`. (The only case when it isn't preferred is when you suspect that you have found a bug in the `MyISAM` code.)

`EXTENDED` is to be used only after you have run a normal check but still get strange errors from a table when MySQL tries to update a row or find a row by key. (This is very unlikely if a normal check has succeeded!)

Some problems reported by `CHECK TABLE` can't be corrected automatically:

- Found row where the `auto_increment` column has the value 0.

This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It's possible to create a row where the `AUTO_INCREMENT` column is 0 by explicitly setting the column to 0 with an `UPDATE` statement.)

This isn't an error in itself, but could cause trouble if you decide to dump the table and restore it or do an `ALTER TABLE` on the table. In this case, the `AUTO_INCREMENT` column changes value according to the rules of `AUTO_INCREMENT` columns, which could cause problems such as a duplicate-key error.

To get rid of the warning, just execute an `UPDATE` statement to set the column to some other value than 0.

13.5.2.4. CHECKSUM TABLE Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]
```

Reports a table checksum.

If `QUICK` is specified, the live table checksum is reported if it is available, or `NULL` otherwise. This is very fast. A live checksum is enabled by specifying the `CHECKSUM=1` table option, currently supported only for `MyISAM` tables. See Section 13.2.5, "CREATE TABLE Syntax".

In `EXTENDED` mode the whole table is read row by row and the checksum is calculated. This can be very slow for large tables.

By default, if neither `QUICK` nor `EXTENDED` is specified, MySQL returns a live checksum if the table storage engine supports it and scans the table otherwise.

`CHECKSUM TABLE` returns `NULL` for non-existent tables. As of MySQL 5.0.3, a warning is generated for this condition.

This statement is implemented in MySQL 4.1.1.

13.5.2.5. OPTIMIZE TABLE Syntax

```
OPTIMIZE [LOCAL | NO_WRITE_TO_BINLOG] TABLE tbl_name [, tbl_name] ...
```

OPTIMIZE TABLE should be used if you have deleted a large part of a table or if you have made many changes to a table with variable-length rows (tables that have VARCHAR, BLOB, or TEXT columns). Deleted records are maintained in a linked list and subsequent INSERT operations reuse old record positions. You can use OPTIMIZE TABLE to reclaim the unused space and to defragment the data file.

In most setups, you need not run OPTIMIZE TABLE at all. Even if you do a lot of updates to variable-length rows, it's not likely that you need to do this more than once a week or month and only on certain tables.

For the moment, OPTIMIZE TABLE works only on MyISAM, BDB and InnoDB tables.

For MyISAM tables, OPTIMIZE TABLE works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the statistics are not up to date (and the repair couldn't be done by sorting the index), update them.

For BDB tables, OPTIMIZE TABLE currently is mapped to ANALYZE TABLE. That was also the case for InnoDB tables before MySQL 4.1.3; starting from this version it is mapped to ALTER TABLE, which rebuilds the table. Rebuilding updates index statistics and frees unused space in the clustered index. See Section 13.5.2.1, "ANALYZE TABLE Syntax".

You can get OPTIMIZE TABLE to work on other table types by starting **mysqld** with the `--skip-new` or `--safe-mode` option; in this case, OPTIMIZE TABLE is just mapped to ALTER TABLE.

Note that MySQL locks the table during the time OPTIMIZE TABLE is running.

Before MySQL 4.1.1, OPTIMIZE TABLE statements are not written to the binary log. As of MySQL 4.1.1, they are written to the binary log unless the optional NO_WRITE_TO_BINLOG keyword (or its alias LOCAL) is used.

13.5.2.6. REPAIR TABLE Syntax

```
REPAIR [LOCAL | NO_WRITE_TO_BINLOG] TABLE
      tbl_name [, tbl_name] ... [QUICK] [EXTENDED] [USE_FRM]
```

REPAIR TABLE repairs a possibly corrupted table. By default, it has the same effect as **myisamchk --recover *tbl_name***. REPAIR TABLE works only on MyISAM tables.

Normally you should never have to run this statement. However, if disaster strikes, REPAIR TABLE is very likely to get back all your data from a MyISAM table. If your tables become corrupted often, you should try to find the reason for it, to eliminate the need to use REPAIR TABLE. See Section A.4.2, "What to Do If MySQL Keeps Crashing". See Section 14.1.4, "MyISAM Table Problems".

The statement returns a table with the following columns:

Column	Value
Table	The table name
Op	Always repair

Msg_type	One of status, error, info, or warning
Msg_text	The message

The REPAIR TABLE statement might produce many rows of information for each repaired table. The last row has a Msg_type value of status and Msg_text normally should be OK. If you don't get OK, you should try repairing the table with **myisamchk --safe-recover**, because REPAIR TABLE does not yet implement all the options of **myisamchk**. We plan to make it more flexible in the future.

If QUICK is given, REPAIR TABLE tries to repair only the index tree. This type of repair is like that done by **myisamchk --recover --quick**.

If you use EXTENDED, MySQL creates the index row by row instead of creating one index at a time with sorting. (Before MySQL 4.1, this might be better than sorting on fixed-length keys if you have long CHAR keys that compress very well.) This type of repair is like that done by **myisamchk --safe-recover**.

As of MySQL 4.0.2, there is a USE_FRM mode for REPAIR TABLE. Use it if the .MYI index file is missing or if its header is corrupted. In this mode, MySQL re-creates the .MYI file using information from the .frm file. This kind of repair cannot be done with **myisamchk**. **Note:** Use this mode **only** if you cannot use regular REPAIR modes. .MYI header contains important table metadata (in particular, current AUTO_INCREMENT value and Delete link) that are lost in REPAIR ... USE_FRM. Don't use USE_FRM if the table is compressed, as this information is also stored in .MYI file.

Before MySQL 4.1.1, REPAIR TABLE statements are not written to the binary log. As of MySQL 4.1.1, they are written to the binary log unless the optional NO_WRITE_TO_BINLOG keyword (or its alias LOCAL) is used.

Warning: If the server dies during a REPAIR TABLE operation, it's essential after restarting it that you immediately execute another REPAIR TABLE statement for the table before performing any other operations on it. (It's always good to start by making a backup.) In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely, but possible scenario.

13.5.2.7. RESTORE TABLE Syntax

```
RESTORE TABLE tbl_name [, tbl_name] ... FROM '/path/to/backup/directory'
```

Restores the table or tables from a backup that was made with BACKUP TABLE. Existing tables are not overwritten; if you try to restore over an existing table, you get an error. Just as BACKUP TABLE, RESTORE TABLE currently works only for MyISAM tables. The directory should be specified as a full pathname.

The backup for each table consists of its .frm format file and .MYD data file. The restore operation restores those files, then uses them to rebuild the .MYI index file. Restoring takes longer than backing up due to the need to rebuild the indexes. The more indexes the table has, the longer it takes.

The statement returns a table with the following columns:

Column	Value
Table	The table name
Op	Always restore
Msg_type	One of status, error, info, or warning
Msg_text	The message

13.5.3. SET Syntax

```
SET variable_assignment [, variable_assignment] ...
```

variable_assignment:

```
  user_var_name = expr
  | [GLOBAL | SESSION] system_var_name = expr
  | @@[global. | session.]system_var_name = expr
```

SET sets different types of variables that affect the operation of the server or your client. It can be used to assign values to user variables or system variables.

The SET PASSWORD statement for assigning account passwords is described in See Section 13.5.1.5, “SET PASSWORD Syntax”.

In MySQL 4.0.3, we added the GLOBAL and SESSION options and allowed most important system variables to be changed dynamically at runtime. The system variables that you can set at runtime are described in Section 5.3.3.1, “Dynamic System Variables”.

In older versions of MySQL, SET OPTION is used instead of SET, but this is deprecated; just leave out the word OPTION.

The following example show the different syntaxes you can use to set variables.

A user variable is written as @*var_name* and can be set as follows:

```
SET @var_name = expr;
```

Further information about user variables is given in Section 9.3, “User Variables”.

System variables can be referred to in SET statements as *var_name*. The name optionally can be preceded by GLOBAL or @@global. to indicate explicitly that the variable is a global variable, or by SESSION, @@session., or @@ to indicate that it is a session variable. LOCAL and @@local. are synonyms for SESSION and @@session.. If no modifier is present, SET sets the session variable.

The @@*var_name* syntax for system variables is supported to make MySQL syntax compatible with some other database systems.

If you set several system variables in the same statement, the last used GLOBAL or SESSION option is used for variables that have no mode specified.

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

If you set a system variable using SESSION (the default), the value remains in effect until the current session ends or until you set the variable to a different value. If you set a system variable using GLOBAL, which requires the SUPER privilege, the value is remembered and used for new connections until the server restarts. If you want to make a variable setting permanent, you should put it in an option file. See Section 4.3.2, “Using Option Files”.

To prevent incorrect usage, MySQL produces an error if you use SET GLOBAL with a variable that can only be used with SET SESSION or if you do not specify GLOBAL when setting a global variable.

If you want to set a SESSION variable to the GLOBAL value or a GLOBAL value to the compiled-in MySQL default value, you can set it to DEFAULT. For example, the following two statements are identical in setting the session value of max_join_size to the global value:

```
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

You can get a list of most system variables with `SHOW VARIABLES`. See Section 13.5.4.19, “`SHOW VARIABLES Syntax`”. To get a specific variable name or list of names that match a pattern, use a `LIKE` clause:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW GLOBAL VARIABLES LIKE 'max_join_size';
```

You can also get the value for a specific value by using the `@@[global.|local.]var_name` syntax with `SELECT`:

```
SELECT @@max_join_size, @@global.max_join_size;
```

When you retrieve a variable with `SELECT @@var_name` (that is, you do not specify `global.`, `session.`, or `local.`), MySQL returns the `SESSION` value if it exists and the `GLOBAL` value otherwise.

The following list describes variables that have non-standard syntax or that are not described in the list of system variables that is found in Section 5.3.3, “`Server System Variables`”. Although these variables are not displayed by `SHOW VARIABLES`, you can obtain their values with `SELECT` (with the exception of `CHARACTER SET` and `SET NAMES`). For example:

```
mysql> SELECT @@AUTOCOMMIT;
```

```
+-----+
| @@autocommit |
+-----+
|              1 |
+-----+
```

- `AUTOCOMMIT = {0 | 1}`

Set the autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you have to use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If you change `AUTOCOMMIT` mode from 0 to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See Section 13.4.1, “`START TRANSACTION, COMMIT, and ROLLBACK Syntax`”.

- `BIG_TABLES = {0 | 1}`

If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table tbl_name is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). As of MySQL 4.0, you should normally never need to set this variable, because MySQL automatically converts in-memory tables to disk-based tables as necessary. This variable previously was named `SQL_BIG_TABLES`.

- `CHARACTER SET {charset_name | DEFAULT}`

This maps all strings from and to the client with the given mapping. Before MySQL 4.1, the only allowable value for `charset_name` is `cp1251_koi8`, but you can add new mappings by editing the `sql/convert.cc` file in the MySQL source distribution. As of MySQL 4.1.1, `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`.

The default mapping can be restored by using a value of `DEFAULT`.

Note that the syntax for `SET CHARACTER SET` differs from that for setting most other options.

- `FOREIGN_KEY_CHECKS = {0 | 1}`

If set to 1 (the default), foreign key constraints for InnoDB tables are checked. If set to 0, they are ignored. Disabling foreign key checking can be useful for reloading InnoDB tables in an order different than that required by their parent/child relationships. This variable was added in MySQL 3.23.52. See Section 15.7.4, “FOREIGN KEY Constraints”.

- `IDENTITY = value`

The variable is a synonym for the `LAST_INSERT_ID` variable. It exists for compatibility with other databases. As of MySQL 3.23.25, you can read its value with `SELECT @@IDENTITY`. As of MySQL 4.0.3, you can also set its value with `SET IDENTITY`.

- `INSERT_ID = value`

Set the value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `LAST_INSERT_ID = value`

Set the value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `NAMES {'charset_name' | DEFAULT}`

`SET NAMES` sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`.

The default mapping can be restored by using a value of `DEFAULT`.

Note that the syntax for `SET NAMES` differs from that for setting most other options. This statement is available as of MySQL 4.1.0.

- `SQL_NOTES = {0 | 1}`

When set to 1 (the default), warnings of Note level are recorded. When set to 0, Note warnings are suppressed. **mysqldump** includes output to set this variable to 0 so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation. `SQL_NOTES` was added in MySQL 4.1.11/5.0.3.

- `SQL_AUTO_IS_NULL = {0 | 1}`

If set to 1 (the default), you can find the last inserted row for a table that contains an

AUTO_INCREMENT column by using the following construct:

```
WHERE auto_increment_column IS NULL
```

This behavior is used by some ODBC programs, such as Access. SQL_AUTO_IS_NULL was added in MySQL 3.23.52.

- SQL_BIG_SELECTS = {0 | 1}

If set to 0, MySQL aborts SELECT statements that probably take a very long time (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable WHERE statement has been issued. The default value for a new connection is 1, which allows all SELECT statements.

If you set the `max_join_size` system variable to a value other than DEFAULT, SQL_BIG_SELECTS is set to 0.

- SQL_BUFFER_RESULT = {0 | 1}

SQL_BUFFER_RESULT forces results from SELECT statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. This variable was added in MySQL 3.23.13.

- SQL_LOG_BIN = {0 | 1}

If set to 0, no logging is done to the binary log for the client. The client must have the SUPER privilege to set this option. This variable was added in MySQL 3.23.16.

- SQL_LOG_OFF = {0 | 1}

If set to 1, no logging is done to the general query log for this client. The client must have the SUPER privilege to set this option.

- SQL_LOG_UPDATE = {0 | 1}

If set to 0, no logging is done to the update log for the client. The client must have the SUPER privilege to set this option. This variable was added in MySQL 3.22.5. Starting from MySQL 5.0.0, it is deprecated and is mapped to SQL_LOG_BIN (see Section D.1.8, “Changes in release 5.0.0 (22 Dec 2003: Alpha)”).

- SQL_QUOTE_SHOW_CREATE = {0 | 1}

If set to 1, SHOW CREATE TABLE quotes table and column names. If set to 0, quoting is disabled. This option is enabled by default so that replication works for tables with table and column names that require quoting. This variable was added in MySQL 3.23.26. Section 13.5.4.5, “SHOW CREATE TABLE Syntax”.

- SQL_SAFE_UPDATES = {0 | 1}

If set to 1, MySQL aborts UPDATE or DELETE statements that do not use a key in the WHERE clause or a LIMIT clause. This makes it possible to catch UPDATE or DELETE statements where keys are not used properly and that would probably change or delete a large number of rows. This variable was added in MySQL 3.22.32.

- SQL_SELECT_LIMIT = {value | DEFAULT}

The maximum number of records to return from SELECT statements. The default value for a new connection is “unlimited.” If you have changed the limit, the default value can be restored by using a SQL_SELECT_LIMIT value of DEFAULT.

If a SELECT has a LIMIT clause, the LIMIT takes precedence over the value of SQL_SELECT_LIMIT.

SQL_SELECT_LIMIT does not apply to SELECT statements executed within stored routines. It also does not apply to SELECT statements that do not produce a result set to be returned to the client. These include SELECT statements in subqueries, CREATE TABLE ... SELECT, and INSERT INTO ... SELECT.

- SQL_WARNINGS = {0 | 1}

This variable controls whether single-row INSERT statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string. This variable was added in MySQL 3.22.11.

- TIMESTAMP = {*timestamp_value* | DEFAULT}

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. *timestamp_value* should be a Unix epoch timestamp, not a MySQL timestamp.

- UNIQUE_CHECKS = {0 | 1}

If set to 1 (the default), uniqueness checks for secondary indexes in InnoDB tables are performed. If set to 0, uniqueness checks are not done for index entries inserted into InnoDB's insert buffer. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to InnoDB. This variable was added in MySQL 3.23.52.

13.5.4. SHOW Syntax

SHOW has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [LIKE 'pattern']
SHOW CREATE DATABASE db_name
SHOW CREATE TABLE tbl_name
SHOW DATABASES [LIKE 'pattern']
SHOW ENGINE engine_name {LOGS | STATUS }
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW INNODB STATUS
SHOW [BDB] LOGS
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW [GLOBAL | SESSION] STATUS [LIKE 'pattern']
SHOW TABLE STATUS [FROM db_name] [LIKE 'pattern']
SHOW [OPEN] TABLES [FROM db_name] [LIKE 'pattern']
SHOW [GLOBAL | SESSION] VARIABLES [LIKE 'pattern']
SHOW WARNINGS [LIMIT [offset,] row_count]
```

The SHOW statement also has forms that provide information about replication master and slave servers and are described in Section 13.6, “Replication Statements”:

```
SHOW BINLOG EVENTS
SHOW MASTER LOGS
SHOW MASTER STATUS
```

```
SHOW SLAVE HOSTS
SHOW SLAVE STATUS
```

If the syntax for a given SHOW statement includes a LIKE *'pattern'* part, *'pattern'* is a string that can contain the SQL '%' and '_' wildcard characters. The pattern is useful for restricting statement output to matching values.

13.5.4.1. SHOW CHARACTER SET Syntax

```
SHOW CHARACTER SET [LIKE 'pattern']
```

The SHOW CHARACTER SET statement shows all available character sets. It takes an optional LIKE clause that indicates which character set names to match. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
```

Charset	Description	Default collation	Maxlen
latin1	ISO 8859-1 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1

The Maxlen column shows the maximum number of bytes used to store one character.

SHOW CHARACTER SET is available as of MySQL 4.1.0.

13.5.4.2. SHOW COLLATION Syntax

```
SHOW COLLATION [LIKE 'pattern']
```

The output from SHOW COLLATION includes all available character sets. It takes an optional LIKE clause that indicates which collation names to match. For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
```

Collation	Charset	Id	Default	Compiled	Sortlen
latin1_german1_ci	latin1	5			0
latin1_swedish_ci	latin1	8	Yes	Yes	0
latin1_danish_ci	latin1	15			0
latin1_german2_ci	latin1	31		Yes	2
latin1_bin	latin1	47		Yes	0
latin1_general_ci	latin1	48			0
latin1_general_cs	latin1	49			0
latin1_spanish_ci	latin1	94			0

The Default column indicates whether a collation is the default for its character set. Compiled indicates whether the character set is compiled into the server. Sortlen is related to the amount of memory required to sort strings expressed in the character set.

SHOW COLLATION is available as of MySQL 4.1.0.

13.5.4.3. SHOW COLUMNS Syntax

```
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [LIKE 'pattern']
```

SHOW COLUMNS displays information about the columns in a given table. It also works for views as of MySQL 5.0.1.

If the column types differ from what you expect them to be based on your CREATE TABLE statement, note that MySQL sometimes changes column types when you create or alter a table. The conditions for which this occurs are described in Section 13.2.5.1, “Silent Column Specification Changes”.

The FULL keyword can be used from MySQL 3.23.32 on. It causes the output to include the privileges you have for each column. As of MySQL 4.1, FULL also causes any per-column comments to be displayed.

You can use *db_name.tbl_name* as an alternative to the *tbl_name FROM db_name* syntax. These two statements are equivalent:

```
mysql> SHOW COLUMNS FROM mytable FROM mydb;
mysql> SHOW COLUMNS FROM mydb.mytable;
```

SHOW FIELDS is a synonym for SHOW COLUMNS. You can also list a table's columns with the **mysqlshow db_name tbl_name** command.

The DESCRIBE statement provides information similar to SHOW COLUMNS. See Section 13.3.1, “DESCRIBE Syntax (Get Information About Columns)”.

13.5.4.4. SHOW CREATE DATABASE Syntax

```
SHOW CREATE {DATABASE | SCHEMA} db_name
```

Shows a CREATE DATABASE statement that creates the given database. It was added in MySQL 4.1. SHOW CREATE SCHEMA can be used as of MySQL 5.0.2.

```
mysql> SHOW CREATE DATABASE test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */
```

13.5.4.5. SHOW CREATE TABLE Syntax

```
SHOW CREATE TABLE tbl_name
```

Shows a CREATE TABLE statement that creates the given table. It was added in MySQL 3.23.20. As of MySQL 5.0.1, this statement also works with views.

```
mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE t (
  id INT(11) default NULL auto_increment,
  s char(60) default NULL,
  PRIMARY KEY (id)
) TYPE=MyISAM
```

SHOW CREATE TABLE quotes table and column names according to the value of the SQL_QUOTE_SHOW_CREATE option. Section 13.5.3, “SET Syntax”.

13.5.4.6. SHOW DATABASES Syntax

```
SHOW {DATABASES | SCHEMAS} [LIKE 'pattern']
```

SHOW DATABASES lists the databases on the MySQL server host. You can also get this list using the **mysqlshow** command. As of MySQL 4.0.2, you see only those databases for which you have some kind of privilege, if you don't have the global SHOW DATABASES privilege.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the SHOW DATABASES privilege.

SHOW SCHEMAS can be used as of MySQL 5.0.2

13.5.4.7. SHOW ENGINE Syntax

```
SHOW ENGINE engine_name {LOGS | STATUS }
```

SHOW ENGINE displays log or status information about storage engines. The following statements currently are supported:

```
SHOW ENGINE BDB LOGS
SHOW ENGINE INNODB STATUS
```

SHOW ENGINE BDB LOGS displays status information about existing BDB log files. It returns the following fields:

- File

The full path to the log file.

- Type

The log file type (BDB for Berkeley DB log files).

- Status

The status of the log file (FREE if the file can be removed, or IN USE if the file is needed by the transaction subsystem)

SHOW ENGINE INNODB STATUS displays extensive information about the state of the InnoDB storage engine.

Older (and now deprecated) synonyms for these statements are SHOW [BDB] LOGS and SHOW INNODB STATUS.

SHOW ENGINE can be used as of MySQL 4.1.2.

13.5.4.8. SHOW ENGINES Syntax

```
SHOW [STORAGE] ENGINES
```

SHOW ENGINES shows you status information about the storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. This statement is implemented in MySQL 4.1.2. SHOW TABLE TYPES is a deprecated synonym.

```
mysql> SHOW ENGINES\G
***** 1. row *****
Engine: MyISAM
Support: DEFAULT
Comment: Default engine as of MySQL 3.23 with great performance
```

```

***** 2. row *****
Engine: HEAP
Support: YES
Comment: Alias for MEMORY
***** 3. row *****
Engine: MEMORY
Support: YES
Comment: Hash based, stored in memory, useful for temporary tables
***** 4. row *****
Engine: MERGE
Support: YES
Comment: Collection of identical MyISAM tables
***** 5. row *****
Engine: MRG_MYISAM
Support: YES
Comment: Alias for MERGE
***** 6. row *****
Engine: ISAM
Support: NO
Comment: Obsolete storage engine, now replaced by MyISAM
***** 7. row *****
Engine: MRG_ISAM
Support: NO
Comment: Obsolete storage engine, now replaced by MERGE
***** 8. row *****
Engine: InnoDB
Support: YES
Comment: Supports transactions, row-level locking, and foreign keys
***** 9. row *****
Engine: INNODB
Support: YES
Comment: Alias for INNODB
***** 10. row *****
Engine: BDB
Support: YES
Comment: Supports transactions and page-level locking
***** 11. row *****
Engine: BERKELEYDB
Support: YES
Comment: Alias for BDB
***** 12. row *****
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables
***** 13. row *****
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
***** 14. row *****
Engine: EXAMPLE
Support: YES
Comment: Example storage engine
***** 15. row *****
Engine: ARCHIVE
Support: YES
Comment: Archive storage engine
***** 16. row *****
Engine: CSV
Support: YES
Comment: CSV storage engine
***** 17. row *****
Engine: FEDERATED
Support: YES
Comment: Federated MySQL storage engine

```

A Support value indicates whether the particular storage engine is supported, and which is the default engine. For example, if the server is started with the `--default-table-type=InnoDB` option, then the Support value for the InnoDB row has the value `DEFAULT`.

13.5.4.9. SHOW ERRORS Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]  
SHOW COUNT(*) ERRORS
```

This statement is similar to `SHOW WARNINGS`, except that instead of displaying errors, warnings, and notes, it displays only errors. `SHOW ERRORS` is available as of MySQL 4.1.0.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.1.7, “`SELECT` Syntax”.

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```
SHOW COUNT(*) ERRORS;  
SELECT @@error_count;
```

For more information, see Section 13.5.4.20, “`SHOW WARNINGS` Syntax”.

13.5.4.10. SHOW GRANTS Syntax

```
SHOW GRANTS FOR user
```

This statement lists the `GRANT` statements that must be issued to duplicate the privileges for a MySQL user account.

```
mysql> SHOW GRANTS FOR 'root'@'localhost';  
+-----+  
| Grants for root@localhost |  
+-----+  
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |  
+-----+
```

As of MySQL 4.1.2, to list privileges for the current session, you can use any of the following statements:

```
SHOW GRANTS;  
SHOW GRANTS FOR CURRENT_USER;  
SHOW GRANTS FOR CURRENT_USER();
```

Before MySQL 4.1.2, you can find out what user the session was authenticated as by selecting the value of the `CURRENT_USER()` function (new in MySQL 4.0.6). Then use that value in the `SHOW GRANTS` statement. See Section 12.8.3, “Information Functions”.

`SHOW GRANTS` is available as of MySQL 3.23.4.

13.5.4.11. SHOW INDEX Syntax

```
SHOW INDEX FROM tbl_name [FROM db_name]
```

`SHOW INDEX` returns table index information in a format that resembles the `SQLStatistics` call in ODBC.

`SHOW INDEX` returns the following fields:

- Table

The name of the table.

- `Non_unique`
0 if the index can't contain duplicates, 1 if it can.
- `Key_name`
The name of the index.
- `Seq_in_index`
The column sequence number in the index, starting with 1.
- `Column_name`
The column name.
- `Collation`
How the column is sorted in the index. In MySQL, this can have values 'A' (Ascending) or NULL (Not sorted).
- `Cardinality`
The number of unique values in the index. This is updated by running `ANALYZE TABLE` or `myisamchk -a`. `Cardinality` is counted based on statistics stored as integers, so it's not necessarily accurate for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.
- `Sub_part`
The number of indexed characters if the column is only partly indexed. NULL if the entire column is indexed.
- `Packed`
Indicates how the key is packed. NULL if it is not.
- `Null`
Contains YES if the column may contain NULL. If not, the column contains NO as of MySQL 5.0.3, and ' ' before that.
- `Index_type`
The index method used (BTREE, FULLTEXT, HASH, RTREE).
- `Comment`
Various remarks. Before MySQL 4.0.2 when the `Index_type` column was added, `Comment` indicates whether an index is FULLTEXT.

The `Packed` and `Comment` columns were added in MySQL 3.23.0. The `Null` and `Index_type` columns were added in MySQL 4.0.2.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. These two statements are equivalent:

```
mysql> SHOW INDEX FROM mytable FROM mydb;  
mysql> SHOW INDEX FROM mydb.mytable;
```

`SHOW KEYS` is a synonym for `SHOW INDEX`. You can also list a table's indexes with the

`mysqlshow -k db_name tbl_name` command.

13.5.4.12. SHOW INNODB STATUS Syntax

`SHOW INNODB STATUS`

This statement shows extensive information about the state of the InnoDB storage engine. As of MySQL 4.1.2, it is deprecated and `SHOW ENGINE INNODB STATUS` should be used instead. See Section 13.5.4.7, “SHOW ENGINE Syntax”.

13.5.4.13. SHOW LOGS Syntax

`SHOW [BDB] LOGS`

`SHOW LOGS` displays status information about existing BDB log files. It was implemented in MySQL 3.23.29. An alias for it (available as of MySQL 4.1.1) is `SHOW BDB LOGS`. As of MySQL 4.1.2, this statement is deprecated and `SHOW ENGINE BDB LOGS` should be used instead. See Section 13.5.4.7, “SHOW ENGINE Syntax”.

13.5.4.14. SHOW PRIVILEGES Syntax

`SHOW PRIVILEGES`

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. This statement is implemented as of MySQL 4.1.0. The output depends on the version of your server.

```
mysql> SHOW PRIVILEGES\G
***** 1. row *****
Privilege: Alter
Context: Tables
Comment: To alter the table
***** 2. row *****
Privilege: Alter routine
Context: Functions,Procedures
Comment: To alter or drop stored functions/procedures
***** 3. row *****
Privilege: Create
Context: Databases,Tables,Indexes
Comment: To create new databases and tables
***** 4. row *****
Privilege: Create routine
Context: Functions,Procedures
Comment: To use CREATE FUNCTION/PROCEDURE
***** 5. row *****
Privilege: Create temporary tables
Context: Databases
Comment: To use CREATE TEMPORARY TABLE
***** 6. row *****
Privilege: Create view
Context: Tables
Comment: To create new views
***** 7. row *****
Privilege: Delete
Context: Tables
Comment: To delete existing rows
***** 8. row *****
Privilege: Drop
Context: Databases,Tables
Comment: To drop databases, tables, and views
***** 9. row *****
Privilege: Execute
Context: Functions,Procedures
Comment: To execute stored routines
***** 10. row *****
```

```

Privilege: File
  Context: File access on server
  Comment: To read and write files on the server
*****
Privilege: Grant option
  Context: Databases,Tables,Functions,Procedures
  Comment: To give to other users those privileges you possess
*****
Privilege: Index
  Context: Tables
  Comment: To create or drop indexes
*****

  Context: Tables
  Comment: To update existing rows
*****
Privilege: Usage
  Context: Server Admin
  Comment: No privileges - allow connect only

```

13.5.4.15. SHOW PROCESSLIST Syntax

SHOW [FULL] PROCESSLIST

SHOW PROCESSLIST shows you which threads are running. You can also get this information using the **mysqladmin processlist** statement. If you have the SUPER privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). See Section 13.5.5.3, “KILL Syntax”. If you don't use the FULL keyword, only the first 100 characters of each query are shown.

Starting from MySQL 4.0.12, the statement reports the hostname for TCP/IP connections in *host_name:client_port* format to make it easier to determine which client is doing what.

This statement is very useful if you get the "too many connections" error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the SUPER privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Some states commonly seen in the output from SHOW PROCESSLIST:

- Checking table

The thread is performing (automatic) checking of the table.

- Closing tables

Means that the thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, then you should verify that you don't have a full disk and that the disk is not in very heavy use.

- Connect Out

Slave connecting to master.

- Copying to tmp table on disk

The temporary result set was larger than *tmp_table_size* and the thread is changing the temporary table from in-memory to disk-based format to save memory.

- Creating tmp table

The thread is creating a temporary table to hold a part of the result for the query.

- deleting from main table

The server is executing the first part of a multiple-table delete and deleting only from the first table.

- deleting from reference tables

The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- Flushing tables

The thread is executing FLUSH TABLES and is waiting for all threads to close their tables.

- Killed

Someone has sent a kill to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as

the other thread releases its lock.

- Locked

The query is locked by another query.

- Sending data

The thread is processing rows for a `SELECT` statement and also is sending data to the client.

- Sorting for group

The thread is doing a sort to satisfy a `GROUP BY`.

- Sorting for order

The thread is doing a sort to satisfy a `ORDER BY`.

- Opening tables

The thread is trying to open a table. This should be very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished.

- Removing duplicates

The query was using `SELECT DISTINCT` in such a way that MySQL couldn't optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- Reopen table

The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- Repair by sorting

The repair code is using sorting to create indexes.

- Repair with keycache

The repair code is using creating keys one by one through the key cache. This is much slower than `Repair by sorting`.

- Searching rows for update

The thread is doing a first phase to find all matching rows before updating them. This has to be done if the `UPDATE` is changing the index that is used to find the involved rows.

- Sleeping

The thread is waiting for the client to send a new statement to it.

- System lock

The thread is waiting to get an external system lock for the table. If you are not using multiple **mysqld** servers that are accessing the same tables, you can disable system locks with the `--skip-external-locking` option.

- Upgrading lock

The `INSERT DELAYED` handler is trying to get a lock for the table to insert rows.

- Updating

The thread is searching for rows to update and updating them.

- User Lock

The thread is waiting on a `GET_LOCK()`.

- Waiting for tables

The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to be able to reopen the table, it must wait until all other threads have closed the table in question.

This notification happens if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- waiting for handler insert

The `INSERT DELAYED` handler has processed all pending inserts and is waiting for new ones.

Most states correspond to very quick operations. If a thread stays in any of these states for many seconds, there might be a problem that needs to be investigated.

There are some other states that are not mentioned in the preceding list, but many of them are useful only for finding bugs in the server.

13.5.4.16. SHOW STATUS Syntax

```
SHOW [GLOBAL | SESSION] STATUS [LIKE 'pattern']
```

`SHOW STATUS` provides server status information. This information also can be obtained using the `mysqladmin extended-status` command.

Partial output is shown here. The list of variables and their values may be different for your server. The meaning of each variable is given in See Section 5.3.4, “Server Status Variables”.

```
mysql> SHOW STATUS;
```

Variable_name	Value
Aborted_clients	0
Aborted_connects	0
Bytes_received	155372598
Bytes_sent	1176560426
Connections	30023
Created_tmp_disk_tables	0
Created_tmp_tables	8340
Created_tmp_files	60
...	
Open_tables	1
Open_files	2
Open_streams	0
Opened_tables	44600
Questions	2026873
...	
Table_locks_immediate	1920382
Table_locks_waited	0
Threads_cached	0
Threads_created	30022
Threads_connected	1
Threads_running	1
Uptime	80380

```
+-----+-----+
```

With a `LIKE` clause, the statement displays only those variables that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Key_blocks_used | 14955 |
| Key_read_requests | 96854827 |
| Key_reads | 162040 |
| Key_write_requests | 7589728 |
| Key_writes | 3813196 |
+-----+-----+
```

The `GLOBAL` and `SESSION` options are new in MySQL 5.0.2. With `GLOBAL`, you get the status values for all connections to MySQL. With `SESSION`, you get the status values for the current connection. If you use neither option, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`.

Note that some status variables only have a global value. For these you get the same value for both `GLOBAL` and `SESSION`.

13.5.4.17. SHOW TABLE STATUS Syntax

```
SHOW TABLE STATUS [FROM db_name] [LIKE 'pattern']
```

`SHOW TABLE STATUS` works like `SHOW TABLE`, but provides a lot of information about each table. You can also get this list using the `mysqlshow --status db_name` command. This statement was added in MySQL 3.23. As of MySQL 5.0.1, it also displays information about views.

`SHOW TABLE STATUS` returns the following fields:

- **Name**
The name of the table.
- **Engine**
The storage engine for the table. Before MySQL 4.1.2, this value is labeled as `Type`. See Chapter 14, *MySQL Storage Engines and Table Types*.
- **Version**
The version number of the table's `.frm` file.
- **Row_format**
The row storage format (`Fixed`, `Dynamic`, `Compressed`, `Redundant`, `Compact`). Starting with MySQL/InnoDB 5.0.3, the format of InnoDB tables is reported as `Redundant` or `Compact`. Before 5.0.3, InnoDB tables are always in the `Redundant` format.
- **Rows**
The number of rows. Some storage engines, such as `MyISAM` and `ISAM`, store the exact count.

For other storage engines, such as `InnoDB`, this value is an approximation, and may vary from the actual value by as much as 40 to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.
- **Avg_row_length**

The average row length.

- `Data_length`

The length of the data file.

- `Max_data_length`

The maximum length of the data file. This is the total number of data bytes that can be stored in the table, given the data pointer size used.

- `Index_length`

The length of the index file.

- `Data_free`

The number of allocated but unused bytes.

- `Auto_increment`

The next `AUTO_INCREMENT` value.

- `Create_time`

When the table was created.

- `Update_time`

When the data file was last updated.

- `Check_time`

When the table was last checked.

- `Collation`

The table's character set and collation. (New in 4.1.1)

- `Checksum`

The live checksum value (if any). (New in 4.1.1)

- `Create_options`

Extra options used with `CREATE TABLE`.

- `Comment`

The comment used when creating the table (or some information why MySQL couldn't access the table information).

In the table comment, InnoDB tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for just that table.

For MEMORY (HEAP) tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

For views, all the fields displayed by `SHOW TABLE STATUS` are NULL except that Name indic-

ates the view name and `Comment` says view.

13.5.4.18. SHOW TABLES Syntax

```
SHOW [FULL|OPEN] TABLES [FROM db_name] [LIKE 'pattern']
```

`SHOW TABLES` lists the non-TEMPORARY tables in a given database. You can also get this list using the `mysqlshow db_name` command.

Before MySQL 5.0.1, the output from `SHOW TABLES` contains a single column of table names. Beginning with MySQL 5.0.1, also lists the views in the database. As of MySQL 5.0.2, the `FULL` modifier is supported such that `SHOW FULL TABLES` displays a second output column. Values in the second column are `BASE TABLE` for a table and `VIEW` for a view.

Note: If you have no privileges for a table, the table does not show up in the output from `SHOW TABLES` or `mysqlshow db_name`.

`SHOW OPEN TABLES` lists the tables that are currently open in the table cache. See Section 7.4.8, “How MySQL Opens and Closes Tables”. The `Comment` field in the output tells how many times the table is cached and `in_use`. `OPEN` can be used from MySQL 3.23.33 on.

13.5.4.19. SHOW VARIABLES Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES [LIKE 'pattern']
```

`SHOW VARIABLES` shows the values of some MySQL system variables. This information also can be obtained using the `mysqladmin variables` command.

The `GLOBAL` and `SESSION` options are new in MySQL 4.0.3. With `GLOBAL`, you get the values that are used for new connections to MySQL. With `SESSION`, you get the values that are in effect for the current connection. If you use neither option, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`.

If the default values are unsuitable, you can set most of these variables using command-line options when `mysqld` starts or at runtime with the `SET` statement. See Section 5.3.1, “`mysqld` Command-Line Options” and Section 13.5.3, “`SET` Syntax”.

Partial output is shown here. The list of variables and their values may be different for your server. The meaning of each variable is given in See Section 5.3.3, “Server System Variables”. Information about tuning them is provided in Section 7.5.2, “Tuning Server Parameters”.

```
mysql> SHOW VARIABLES;
```

Variable_name	Value
back_log	50
basedir	/usr/local/mysql
bdb_cache_size	8388572
bdb_log_buffer_size	32768
bdb_home	/usr/local/mysql
...	
max_connections	100
max_connect_errors	10
max_delayed_threads	20
max_error_count	64
max_heap_table_size	16777216
max_join_size	4294967295
max_relay_log_size	0
max_sort_length	1024
...	
timezone	EEST
tmp_table_size	33554432
tmpdir	/tmp/:/mnt/hd2/tmp/
version	4.0.4-beta

wait_timeout	28800
--------------	-------

With a LIKE clause, the statement displays only those variables that match the pattern:

```
mysql> SHOW VARIABLES LIKE 'have%';
```

Variable_name	Value
have_bdb	YES
have_innodb	YES
have_isam	YES
have_raid	NO
have_symlink	DISABLED
have_openssl	YES
have_query_cache	YES

13.5.4.20. SHOW WARNINGS Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

SHOW WARNINGS shows the error, warning, and note messages that resulted from the last statement that generated messages, or nothing if the last statement that used a table generated no messages. This statement is implemented as of MySQL 4.1.0. A related statement, SHOW ERRORS, shows only the errors. See Section 13.5.4.9, “SHOW ERRORS Syntax”.

The list of messages is reset for each new statement that uses a table.

The SHOW COUNT(*) WARNINGS statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the warning_count variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

The value of warning_count might be greater than the number of messages displayed by SHOW WARNINGS if the max_error_count system variable is set low enough that not all messages are stored. An example shown later in this section demonstrates how this can happen.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.1.7, “SELECT Syntax”.

The MySQL server sends back the total number of errors, warnings, and notes resulting from the last statement. If you are using the C API, this value can be obtained by calling mysql_warning_count(). See Section 24.2.3.61, “mysql_warning_count()”.

Note that the framework for warnings was added in MySQL 4.1.0, at which point many statements did not generate warnings. In 4.1.1, the situation is much improved, with warnings generated for statements such as LOAD DATA INFILE and DML statements such as INSERT, UPDATE, CREATE TABLE, and ALTER TABLE.

The following DROP TABLE statement results in a note:

```
mysql> DROP TABLE IF EXISTS no_such_table;
mysql> SHOW WARNINGS;
```

Level	Code	Message
Note	1051	Unknown table 'no_such_table'

Here is a simple example that shows a syntax warning for CREATE TABLE and conversion warnings for INSERT:

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4)) TYPE=MyISAM;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1287
Message: 'TYPE=storage_engine' is deprecated, use
'ENGINE=storage_engine' instead
1 row in set (0.00 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'),(NULL,'test'),
-> (300,'Open Source');
Query OK, 3 rows affected, 4 warnings (0.01 sec)
Records: 3 Duplicates: 0 Warnings: 4

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 1
***** 2. row *****
Level: Warning
Code: 1263
Message: Data truncated, NULL supplied to NOT NULL column 'a' at row 2
***** 3. row *****
Level: Warning
Code: 1264
Message: Data truncated, out of range for column 'a' at row 3
***** 4. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 3
4 rows in set (0.00 sec)
```

The maximum number of error, warning, and note messages to store is controlled by the `max_error_count` system variable. By default, its value is 64. To change the number of messages you want stored, change the value of `max_error_count`. In the following example, the ALTER TABLE statement produces three warning messages, but only one is stored because `max_error_count` has been set to 1:

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 64 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET max_error_count=1;
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SELECT @@warning_count;
+-----+
| @@warning_count |
+-----+
| 3 |
+-----+
1 row in set (0.01 sec)

mysql> SHOW WARNINGS;
```

```

+-----+-----+-----+
| Level   | Code | Message
+-----+-----+-----+
| Warning | 1263 | Data truncated for column 'b' at row 1
+-----+-----+-----+
1 row in set (0.00 sec)

```

To disable warnings, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings have occurred, but none of the messages are stored.

As of MySQL 4.1.11/5.0.3, you can set the `SQL_NOTES` session variable to 0 to cause Note-level warnings not to be recorded.

13.5.5. Other Administrative Statements

13.5.5.1. CACHE INDEX Syntax

```

CACHE INDEX
  tbl_index_list [, tbl_index_list] ...
  IN key_cache_name

tbl_index_list:
  tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]

```

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It is used only for MyISAM tables.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```

mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
+-----+-----+-----+-----+
| Table   | Op                | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+-----+-----+-----+-----+

```

The syntax of `CACHE INDEX` allows you to specify that only particular indexes from a table should be assigned to the cache. However, the current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters can be accessed as members of a structured system variable. See Section 9.4.1, “Structured System Variables”.

A key cache must exist before you can assign indexes to it:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter what client issues the queries.

CACHE INDEX was added in MySQL 4.1.1.

13.5.5.2. FLUSH Syntax

```
FLUSH [LOCAL | NO_WRITE_TO_BINLOG] flush_option [, flush_option] ...
```

You should use the FLUSH statement if you want to clear some of the internal caches MySQL uses. To execute FLUSH, you must have the RELOAD privilege.

flush_option can be any of the following:

- HOSTS

Empties the host cache tables. You should flush the host tables if some of your hosts change IP number or if you get the error message `Host ... is blocked`. When more than `max_connect_errors` errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host tables allows the host to attempt to connect again. See Section A.2.5, “Host '*host_name*' is blocked”. You can start **mysqld** with `--max_connect_errors=999999999` to avoid this error message.

- DES_KEY_FILE

Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

- LOGS

Closes and reopens all log files. If you have specified an update log file or a binary log file without an extension, the extension number of the log file is incremented by one relative to the previous file. If you have used an extension in the file name, MySQL closes and reopens the update log or binary log file. See Section 5.10.3, “The Update Log”. On Unix, this is the same thing as sending a SIGHUP signal to the **mysqld** server (except on some Mac OS X 10.3 versions where **mysqld** ignores SIGHUP and SIGQUIT).

- PRIVILEGES

Reloads the privileges from the grant tables in the `mysql` database.

- QUERY CACHE

Defragment the query cache to better utilize its memory. This statement does not remove any queries from the cache, unlike `RESET QUERY CACHE`.

- STATUS

Resets most status variables to zero. This is something you should use only when debugging a query. See Section 1.6.1.3, “How to Report Bugs or Problems”.

- {TABLE | TABLES} [*tbl_name* [, *tbl_name*] ...]

When no tables are named, closes all open tables and forces all tables in use to be closed. This also flushes the query cache. With one or more table names, flushes only the given tables. `FLUSH TABLES` also removes all query results from the query cache, like the `RESET QUERY CACHE` statement.

- TABLES WITH READ LOCK

Closes all open tables and locks all tables for all databases with a read lock until you execute `UNLOCK TABLES`. This is very convenient way to get backups if you have a filesystem such as Veritas that can take snapshots in time.

- `USER_RESOURCES`

Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity. `FLUSH USER_RESOURCES` does not apply to the limit on maximum simultaneous connections. See Section 13.5.1.3, “GRANT and REVOKE Syntax”.

Before MySQL 4.1.1, `FLUSH` statements are not written to the binary log. As of MySQL 4.1.1, they are written to the binary log unless the optional `NO_WRITE_TO_BINLOG` keyword (or its alias `LOCAL`) is used. Exceptions are that `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK` are not logged in any case because they would cause problems if replicated to a slave.

You can also access some of these statements with the **mysqladmin** utility, using the `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, or `flush-tables` commands.

Take also a look at the `RESET` statement used with replication. See Section 13.5.5.5, “RESET Syntax”.

13.5.5.3. KILL Syntax

```
KILL [CONNECTION | QUERY] thread_id
```

Each connection to **mysqld** runs in a separate thread. You can see which threads are running with the `SHOW PROCESSLIST` statement and kill a thread with the `KILL thread_id` statement.

As of MySQL 5.0.0, `KILL` allows the optional `CONNECTION` or `QUERY` modifiers:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given *thread_id*.
- `KILL QUERY` terminates the statement that the connection currently is executing, but leaves the connection intact.

If you have the `PROCESS` privilege, you can see all threads. If you have the `SUPER` privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the **mysqladmin processlist** and **mysqladmin kill** commands to examine and kill threads.

Note: You currently cannot use `KILL` with the Embedded MySQL Server library, because the embedded server merely runs inside the threads of the host application, it does not create connection threads of its own.

When you do a `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die, because the kill flag is checked only at specific intervals:

- In `SELECT`, `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- During `ALTER TABLE`, the kill flag is checked before each block of rows are read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.

- During UPDATE or DELETE, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. Note that if you are not using transactions, the changes are not rolled back.
- GET_LOCK() aborts and returns NULL.
- An INSERT DELAYED thread quickly flushes (inserts) all rows it has in memory and terminates.
- If the thread is in the table lock handler (state: Locked), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a "disk full" error message.
- Some threads might refuse to be killed. For example, REPAIR TABLE, CHECK TABLE, and OPTIMIZE TABLE cannot be killed before MySQL 4.1 and run to completion. This is changed: REPAIR TABLE and OPTIMIZE TABLE can be killed as of MySQL 4.1.0, as can CHECK TABLE as of MySQL 4.1.3. However, killing a REPAIR TABLE or OPTIMIZE TABLE operation on a MyISAM table results in a table that *is* corrupted and is unusable (reads and writes to it fail) until you optimize or repair it again.

13.5.5.4. LOAD INDEX INTO CACHE Syntax

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
  [[INDEX|KEY] (index_name[, index_name] ...)]
  [IGNORE LEAVES]
```

The LOAD INDEX INTO CACHE statement preloads a table index into the key cache to which it has been assigned by an explicit CACHE INDEX statement, or into the default key cache otherwise. LOAD INDEX INTO CACHE is used only for MyISAM tables.

The IGNORE LEAVES modifier causes only blocks for the non-leaf nodes of the index to be preloaded.

The following statement preloads nodes (index blocks) of indexes of the tables t1 and t2:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
```

Table	Op	Msg_type	Msg_text
test.t1	preload_keys	status	OK
test.t2	preload_keys	status	OK

This statement preloads all index blocks from t1. It preloads only blocks for the non-leaf nodes from t2.

The syntax of LOAD INDEX INTO CACHE allows you to specify that only particular indexes from a table should be preloaded. However, the current implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

LOAD INDEX INTO CACHE was added in MySQL 4.1.1.

13.5.5.5. RESET Syntax

```
RESET reset_option [, reset_option] ...
```

The `RESET` statement is used to clear the state of various server operations. It also acts as a stronger version of the `FLUSH` statement. See Section 13.5.5.2, “`FLUSH` Syntax”.

To execute `RESET`, you must have the `RELOAD` privilege.

`reset_option` can be any of the following:

- `MASTER`

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file. Previously named `FLUSH MASTER`. See Section 13.6.1, “SQL Statements for Controlling Master Servers”.

- `QUERY CACHE`

Removes all query results from the query cache.

- `SLAVE`

Makes the slave forget its replication position in the master binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one. Previously named `FLUSH SLAVE`. See Section 13.6.2, “SQL Statements for Controlling Slave Servers”.

13.6. Replication Statements

This section describes replication-related SQL statements. One group of statements is used for controlling master servers. The other is used for controlling slave servers.

13.6.1. SQL Statements for Controlling Master Servers

Replication can be controlled through the SQL interface. This section discusses statements for managing master replication servers. Section 13.6.2, “SQL Statements for Controlling Slave Servers” discusses statements for managing slave servers.

13.6.1.1. `PURGE MASTER LOGS` Syntax

```
PURGE {MASTER | BINARY} LOGS TO 'log_name'  
PURGE {MASTER | BINARY} LOGS BEFORE 'date'
```

Deletes all the binary logs listed in the log index that are strictly prior to the specified log or date. The logs also are removed from the list recorded in the log index file, so that the given log becomes the first.

Example:

```
PURGE MASTER LOGS TO 'mysql-bin.010';  
PURGE MASTER LOGS BEFORE '2003-04-02 22:46:26';
```

The `BEFORE` variant is available as of MySQL 4.1. Its date argument can be in `'YYYY-MM-DD hh:mm:ss'` format. `MASTER` and `BINARY` are synonyms, but `BINARY` can be used only as of MySQL 4.1.1.

If you have an active slave that currently is reading one of the logs you are trying to delete, this statement does nothing and fails with an error. However, if a slave is dormant and you happen to purge one of the logs it wants to read, the slave is unable to replicate once it comes up. The statement is safe to run while slaves are replicating. You do not need to stop them.

To purge logs, follow this procedure:

1. On each slave server, use `SHOW SLAVE STATUS` to check which log it is reading.
2. Obtain a listing of the logs on the master server with `SHOW MASTER LOGS`.
3. Determine the earliest log among all the slaves. This is the target log. If all the slaves are up to date, this is the last log on the list.
4. Make a backup of all the logs you are about to delete. (The step is optional, but a good idea.)
5. Purge all logs up to but not including the target log.

13.6.1.2. RESET MASTER Syntax

```
RESET MASTER
```

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

This statement was named `FLUSH MASTER` before MySQL 3.23.26.

13.6.1.3. SET SQL_LOG_BIN Syntax

```
SET SQL_LOG_BIN = {0|1}
```

Disables or enables binary logging for the current connection (`SQL_LOG_BIN` is a session variable) if the client connects using an account that has the `SUPER` privilege. The statement is refused with an error if the client does not have that privilege. (Before MySQL 4.1.2, the statement was simply ignored in that case.)

13.6.1.4. SHOW BINLOG EVENTS Syntax

```
SHOW BINLOG EVENTS  
  [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify `'log_name'`, the first binary log is displayed.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.1.7, “`SELECT` Syntax”.

This statement is available as of MySQL 4.0.

13.6.1.5. SHOW MASTER LOGS Syntax

```
SHOW MASTER LOGS  
SHOW BINARY LOGS
```

Lists the binary log files on the server. This statement is used as part of the procedure described in Section 13.6.1.1, “`PURGE MASTER LOGS` Syntax” for determining which logs can be purged.

`SHOW MASTER LOGS` was added in MySQL 3.23.38. As of MySQL 4.1.1, you can also use `SHOW BINARY LOGS`, which is equivalent.

13.6.1.6. SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

Provides status information on the binary log files of the master.

13.6.1.7. SHOW SLAVE HOSTS Syntax

```
SHOW SLAVE HOSTS
```

Displays a list of slaves currently registered with the master. Any slave not started with the `-report-host=slave_name` option is not visible in that list.

13.6.2. SQL Statements for Controlling Slave Servers

Replication can be controlled through the SQL interface. This section discusses statements for managing slave replication servers. Section 13.6.1, “SQL Statements for Controlling Master Servers” discusses statements for managing master servers.

13.6.2.1. CHANGE MASTER TO Syntax

```
CHANGE MASTER TO master_def [, master_def] ...
```

```
master_def:  
  MASTER_HOST = 'host_name'  
  MASTER_USER = 'user_name'  
  MASTER_PASSWORD = 'password'  
  MASTER_PORT = port_num  
  MASTER_CONNECT_RETRY = count  
  MASTER_LOG_FILE = 'master_log_name'  
  MASTER_LOG_POS = master_log_pos  
  RELAY_LOG_FILE = 'relay_log_name'  
  RELAY_LOG_POS = relay_log_pos  
  MASTER_SSL = {0|1}  
  MASTER_SSL_CA = 'ca_file_name'  
  MASTER_SSL_CAPATH = 'ca_directory_name'  
  MASTER_SSL_CERT = 'cert_file_name'  
  MASTER_SSL_KEY = 'key_file_name'  
  MASTER_SSL_CIPHER = 'cipher_list'
```

Changes the parameters that the slave server uses for connecting to and communicating with the master server.

`MASTER_USER`, `MASTER_PASSWORD`, `MASTER_SSL`, `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_KEY`, and `MASTER_SSL_CIPHER` provide information for the slave about how to connect to its master.

The relay log options (`RELAY_LOG_FILE` and `RELAY_LOG_POS`) are available beginning with MySQL 4.0.

The SSL options (`MASTER_SSL`, `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_KEY`, and `MASTER_SSL_CIPHER`) are available beginning with MySQL 4.1.1. You can change these options even on slaves that are compiled without SSL support. They are saved to the `master.info` file, but are ignored until you use a server that has SSL support enabled.

If you don't specify a given parameter, it keeps its old value, except as indicated in the following discussion. For example, if the password to connect to your MySQL master has changed, you just need to issue these statements to tell the slave about the new password:

```
mysql> STOP SLAVE; -- if replication was running  
mysql> CHANGE MASTER TO MASTER_PASSWORD='new3cret';  
mysql> START SLAVE; -- if you want to restart replication
```

There is no need to specify the parameters that do not change (host, port, user, and so forth).

MASTER_HOST and MASTER_PORT are the hostname (or IP address) of the master host and its TCP/IP port. Note that if MASTER_HOST is equal to localhost, then, like in other parts of MySQL, the port may be ignored (if Unix socket files can be used, for example).

If you specify MASTER_HOST or MASTER_PORT, the slave assumes that the master server is different than before (even if you specify a host or port value that is the same as the current value.) In this case, the old values for the master binary log name and position are considered no longer applicable, so if you do not specify MASTER_LOG_FILE and MASTER_LOG_POS in the statement, MASTER_LOG_FILE= ' ' and MASTER_LOG_POS=4 are silently appended to it.

MASTER_LOG_FILE and MASTER_LOG_POS are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. If you specify either of them, you can't specify RELAY_LOG_FILE or RELAY_LOG_POS. If neither of MASTER_LOG_FILE or MASTER_LOG_POS are specified, the slave uses the last coordinates of the *slave SQL thread* before CHANGE MASTER was issued. This ensures that replication has no discontinuity, even if the slave SQL thread was late compared to the slave I/O thread, when you just want to change, say, the password to use. This safe behavior was introduced starting from MySQL 4.0.17 and 4.1.1. (Before these versions, the coordinates used were the last coordinates of the slave I/O thread before CHANGE MASTER was issued. This caused the SQL thread to possibly lose some events from the master, thus breaking replication.)

CHANGE MASTER *deletes all relay log files* and starts a new one, unless you specify RELAY_LOG_FILE or RELAY_LOG_POS. In that case, relay logs are kept; as of MySQL 4.1.1 the relay_log_purge global variable is set silently to 0.

CHANGE MASTER TO updates the contents of the master.info and relay-log.info files.

CHANGE MASTER is useful for setting up a slave when you have the snapshot of the master and have recorded the log and the offset corresponding to it. After loading the snapshot into the slave, you can run CHANGE MASTER TO MASTER_LOG_FILE='log_name_on_master', MASTER_LOG_POS=log_offset_on_master on the slave.

Examples:

```
mysql> CHANGE MASTER TO
->     MASTER_HOST='master2.mycompany.com' ,
->     MASTER_USER='replication' ,
->     MASTER_PASSWORD='big3cret' ,
->     MASTER_PORT=3306 ,
->     MASTER_LOG_FILE='master2-bin.001' ,
->     MASTER_LOG_POS=4 ,
->     MASTER_CONNECT_RETRY=10 ;

mysql> CHANGE MASTER TO
->     RELAY_LOG_FILE='slave-relay-bin.006' ,
->     RELAY_LOG_POS=4025 ;
```

The first example changes the master and master's binary log coordinates. This is used when you want to set up the slave to replicate the master.

The second example shows an operation that is less frequently used. It is done when the slave has relay logs that you want it to execute again for some reason. To do this, the master need not be reachable. You just have to use CHANGE MASTER TO and start the SQL thread (START SLAVE SQL_THREAD).

You can even use the second operation in a non-replication setup with a standalone, non-slave server, to recover after a crash. Suppose that your server has crashed and you have restored a backup. You want to replay the server's own binary logs (not relay logs, but regular binary logs), supposedly named myhost-bin.*. First, make a backup copy of these binary logs in some safe place, in case you don't exactly follow the procedure below and accidentally have the server purge the binary logs. If using MySQL 4.1.1 or newer, use SET GLOBAL relay_log_purge=0 for additional safety. Then start the server without the --log-bin option. Before MySQL 4.0.19, start it with a new (different from before) server id; in newer versions there is no need, just use the -

`--replicate-same-server-id` option. Start it with `--relay-log=myhost-bin` (to make the server believe that these regular binary logs are relay logs) and with `--skip-slave-start`. After the server starts, issue these statements:

```
mysql> CHANGE MASTER TO
->     RELAY_LOG_FILE='myhost-bin.153',
->     RELAY_LOG_POS=410,
->     MASTER_HOST='some_dummy_string';
mysql> START SLAVE SQL_THREAD;
```

The server reads and executes its own binary logs, thus achieving crash recovery. Once the recovery is finished, run `STOP SLAVE`, shut down the server, delete `master.info` and `relay-log.info`, and restart the server with its original options.

For the moment, specifying `MASTER_HOST` (even with a dummy value) is required to make the server think it is a slave. In the future, we plan to add options to get rid of these small constraints.

13.6.2.2. LOAD DATA FROM MASTER Syntax

`LOAD DATA FROM MASTER`

Takes a snapshot of the master and copies it to the slave. It updates the values of `MASTER_LOG_FILE` and `MASTER_LOG_POS` so that the slave starts replicating from the correct position. Any table and database exclusion rules specified with the `--replicate-*-do-*` and `--replicate-*-ignore-*` options are honored. `--replicate-rewrite-db` is *not* taken into account (because one user could, with this option, set up a non-unique mapping such as `--replicate-rewrite-db=db1->db3` and `--replicate-rewrite-db=db2->db3`, which would confuse the slave when it loads the master's tables).

Use of this statement is subject to the following conditions:

- It works only with MyISAM tables.
- It acquires a global read lock on the master while taking the snapshot, which prevents updates on the master during the load operation.

In the future, it is planned to make this statement work with InnoDB tables and to remove the need for a global read lock by using non-blocking online backup.

If you are loading big tables, you might have to increase the values of `net_read_timeout` and `net_write_timeout` on both your master and slave servers. See Section 5.3.3, “Server System Variables”.

Note that `LOAD DATA FROM MASTER` does *not* copy any tables from the `mysql` database. This makes it easy to have different users and privileges on the master and the slave.

The `LOAD DATA FROM MASTER` statement requires the replication account that is used to connect to the master to have the `RELOAD` and `SUPER` privileges on the master and the `SELECT` privilege for all master tables you want to load. All master tables for which the user does not have the `SELECT` privilege are ignored by `LOAD DATA FROM MASTER`. This is because the master hides them from the user: `LOAD DATA FROM MASTER` calls `SHOW DATABASES` to know the master databases to load, but `SHOW DATABASES` returns only databases for which the user has some privilege. See Section 13.5.4.6, “`SHOW DATABASES` Syntax”. On the slave's side, the user that issues `LOAD DATA FROM MASTER` should have grants to drop and create the databases and tables that are copied.

13.6.2.3. LOAD TABLE *tbl_name* FROM MASTER Syntax

`LOAD TABLE tbl_name FROM MASTER`

Transfers a copy of the table from master to the slave. This statement is implemented mainly for debugging of `LOAD DATA FROM MASTER`. It requires that the account used for connecting to the master server has the `RELOAD` and `SUPER` privileges on the master and the `SELECT` privilege on the master table to load. On the slave side, the user that issues `LOAD TABLE FROM MASTER` should have privileges to drop and create the table.

The conditions for `LOAD DATA FROM MASTER` apply here, too. For example, `LOAD TABLE FROM MASTER` works only for `MyISAM` tables. The timeout notes for `LOAD DATA FROM MASTER` apply as well.

13.6.2.4. `MASTER_POS_WAIT()` Syntax

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos)
```

This is a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master's binary log. See Section 12.8.4, "Miscellaneous Functions" for a full description.

13.6.2.5. `RESET SLAVE` Syntax

```
RESET SLAVE
```

Makes the slave forget its replication position in the master's binary logs. This statement is meant to be used for a clean start: It deletes the `master.info` and `relay-log.info` files, all the relay logs, and starts a new relay log.

Note: All relay logs are deleted, even if they have not been totally executed by the slave `SQL` thread. (This is a condition likely to exist on a replication slave if you have issued a `STOP SLAVE` statement or if the slave is highly loaded.)

Connection information stored in the `master.info` file is immediately reset using any values specified in the corresponding startup options. This information includes values such as master host, master port, master user, and master password. If the slave `SQL` thread was in the middle of replicating temporary tables when it was stopped, and `RESET SLAVE` is issued, these replicated temporary tables are deleted on the slave.

This statement was named `FLUSH SLAVE` before MySQL 3.23.26.

13.6.2.6. `SET GLOBAL SQL_SLAVE_SKIP_COUNTER` Syntax

```
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = n
```

Skip the next `n` events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave thread is not running. Otherwise, it produces an error.

Before MySQL 4.0, omit the `GLOBAL` keyword from the statement.

13.6.2.7. `SHOW SLAVE STATUS` Syntax

```
SHOW SLAVE STATUS
```

Provides status information on essential parameters of the slave threads. If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than semicolon to get a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
```

```
Slave_IO_State: Waiting for master to send event
Master_Host: localhost
Master_User: root
Master_Port: 3306
Connect_Retry: 3
Master_Log_File: gbichot-bin.005
Read_Master_Log_Pos: 79
Relay_Log_File: gbichot-relay-bin.005
Relay_Log_Pos: 548
Relay_Master_Log_File: gbichot-bin.005
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
Replicate_Do_DB:
Replicate_Ignore_DB:
Last_Errno: 0
Last_Error:
Skip_Counter: 0
Exec_Master_Log_Pos: 79
Relay_Log_Space: 552
Until_Condition: None
Until_Log_File:
Until_Log_Pos: 0
Master_SSL_Allowed: No
Master_SSL_CA_File:
Master_SSL_CA_Path:
Master_SSL_Cert:
Master_SSL_Cipher:
Master_SSL_Key:
Seconds_Behind_Master: 8
```

Depending on your version of MySQL, you may not see all the fields just shown. In particular, several fields are present only as of MySQL 4.1.1.

SHOW SLAVE STATUS returns the following fields:

- Slave_IO_State

A copy of the State field of the output of SHOW PROCESSLIST for the slave I/O thread. This tells you if the thread is trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. Possible states are listed in Section 6.3, “Replication Implementation Details”. Looking at this field is necessary because, for example, the thread can be running but unsuccessfully trying to connect to the master; only this field makes you aware of the connection problem. The state of the SQL thread is not copied because it is simpler. If it is running, there is no problem; if it is not, you can find the error in the Last_Error field (described below).

This field is present beginning with MySQL 4.1.1.

- Master_Host

The current master host.

- Master_User

The current user used to connect to the master.

- Master_Port

The current master port.

- Connect_Retry

The current value of the --master-connect-retry option.

- `Master_Log_File`
The name of the master binary log file from which the I/O thread is currently reading.
- `Read_Master_Log_Pos`
The position up to which the I/O thread has read in the current master binary log.
- `Relay_Log_File`
The name of the relay log file from which the SQL thread is currently reading and executing.
- `Relay_Log_Pos`
The position up to which the SQL thread has read and executed in the current relay log.
- `Relay_Master_Log_File`
The name of the master binary log file that contains the last event executed by the SQL thread.
- `Slave_IO_Running`
Whether or not the I/O thread is started.
- `Slave_SQL_Running`
Whether or not the SQL thread is started.
- `Replicate_Do_DB, Replicate_Ignore_DB`
The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.

These fields are present beginning with MySQL 4.1.1.
- `Replicate_Do_Table, Replicate_Ignore_Table, Replicate_Wild_Do_Table, Replicate_Wild_Ignore_Table`
The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, if any.

These fields are present beginning with MySQL 4.1.1.
- `Last_Errno, Last_Error`
The error number and error message returned by the most recently executed query. An error number of 0 and message of the empty string mean "no error." If the `Last_Error` value is not empty, it also appears as a message in the slave's error log.

For example:

```
Last_Errno: 1051
Last_Error: error 'Unknown table 'z'' on query 'drop table z'
```

The message indicates that the table `z` existed on the master and was dropped there, but it did not exist on the slave, so `DROP TABLE` failed on the slave. (This might occur, for example, if you forget to copy the table to the slave when setting up replication.)
- `Skip_Counter`
The last used value for `SQL_SLAVE_SKIP_COUNTER`.

- `Exec_Master_Log_Pos`

The position of the last event executed by the SQL thread from the master's binary log (`Relay_Master_Log_File`). (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`) in the master's binary log corresponds to (`Relay_Log_File`, `Relay_Log_Pos`) in the relay log.

- `Relay_Log_Space`

The total combined size of all existing relay logs.

- `Until_Condition`, `Until_Log_File`, `Until_Log_Pos`

The values specified in the UNTIL clause of the `START SLAVE` statement.

`Until_Condition` has these values:

- `None` if no UNTIL clause was specified
- `Master` if the slave is reading until a given position in the master's binary logs
- `Relay` if the slave is reading until a given position in its relay logs

`Until_Log_File` and `Until_Log_Pos` indicate the log filename and position values that define the point at which the SQL thread stops executing.

These fields are present beginning with MySQL 4.1.1.

- `Master_SSL_Allowed`, `Master_SSL_CA_File`, `Master_SSL_CA_Path`, `Master_SSL_Cert`, `Master_SSL_Cipher`, `Master_SSL_Key`

These fields show the SSL parameters used by the slave to connect to the master, if any.

`Master_SSL_Allowed` has these values:

- `Yes` if an SSL connection to the master is allowed
- `No` if an SSL connection to the master is not allowed
- `Ignored` if an SSL connection is allowed but the slave server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the `--master-ca`, `--master-capath`, `--master-cert`, `--master-cipher`, and `--master-key` options.

These fields are present beginning with MySQL 4.1.1.

- `Seconds_Behind_Master`

This field is present beginning with MySQL 4.1.1. It's been experimental and has been changed in MySQL 4.1.9. The following applies to slaves running MySQL 4.1.9 or newer. This field is an indication of how "late" the slave is. When the slave SQL thread is actively running (processing updates), this field is the number of seconds that have elapsed since the timestamp of the last master's event executed by that thread. When that thread has caught up on the slave I/O thread and goes idle waiting for more events from the I/O thread this field is zero. To sum up, this field measures in seconds the time difference between the slave SQL thread and the slave I/O thread.

If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is **not** a good approximation; the slave SQL thread may

quite often be caught up with the slow-reading slave I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the master. In other words, **this column is useful only for fast networks.**

This time difference computation works even though your master and slave don't have identical clocks (the clock difference is computed when the slave I/O thread starts, and assumed to remain constant from then on). `Seconds_Behind_Master` is NULL (which means "unknown") if the slave SQL thread is not running, or if the slave I/O thread is not running or not connected to master. For example if the slave I/O thread is sleeping for `master-connect-retry` seconds before reconnecting, NULL is shown, as the slave cannot know what the master is doing, and thus cannot reliably say how late it is.

This field has one limitation. Indeed the timestamp is preserved through replication, which means that if your master M1 is itself a slave of M0, any event from M1's binlog which has its origin in replication of an event of M0's binlog, has the timestamp of that last event. This enables MySQL to replicate `TIMESTAMP` successfully. But the drawback for `Seconds_Behind_Master` is that if M1 also receives direct updates from clients, then the value randomly goes up and down, because sometimes the last M1's event is from M0 and sometimes it is from a direct update, and so is the last timestamp.

13.6.2.8. START SLAVE Syntax

```
START SLAVE [thread_type [, thread_type] ... ]
START SLAVE [SQL_THREAD] UNTIL
    MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
START SLAVE [SQL_THREAD] UNTIL
    RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos
```

`thread_type`: IO_THREAD | SQL_THREAD

`START SLAVE` with no options starts both of the slave threads. The I/O thread reads queries from the master server and stores them in the relay log. The SQL thread reads the relay log and executes the queries. `START SLAVE` requires the SUPER privilege.

If `START SLAVE` succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they don't manage to connect to the master or read its binary logs, or some other problem). `START SLAVE` does not warn you about this. You must check your slave's error log for error messages generated by the slave threads, or check that they are running fine with `SHOW SLAVE STATUS`.

As of MySQL 4.0.2, you can add `IO_THREAD` and `SQL_THREAD` options to the statement to name which of the threads to start.

As of MySQL 4.1.1, an `UNTIL` clause may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary logs or in the slave relay logs. When the SQL thread reaches that point, it stops. If the `SQL_THREAD` option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the `UNTIL` clause is ignored and a warning is issued.

With an `UNTIL` clause, you must specify both a log filename and position. Do not mix master and relay log options.

Any `UNTIL` condition is reset by a subsequent `STOP SLAVE` statement, a `START SLAVE` statement that includes no `UNTIL` clause, or a server restart.

The `UNTIL` clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate a statement. For example, if an unwise `DROP TABLE` statement was executed on the master, you can use `UNTIL` to tell the slave to execute up to that point but no farther. To find what the event is, use `mysqlbinlog` with the master logs or slave relay logs, or by using a `SHOW BINLOG EVENTS` statement.

If you are using `UNTIL` to have the slave process replicated queries in sections, it is recommended that you start the slave with the `--skip-slave-start` option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The `SHOW SLAVE STATUS` statement includes output fields that display the current values of the `UNTIL` condition.

This statement is called `SLAVE START` before MySQL 4.0.5. For the moment, `SLAVE START` is still accepted for backward compatibility, but is deprecated.

13.6.2.9. STOP SLAVE Syntax

```
STOP SLAVE [thread_type [, thread_type] ... ]
```

```
thread_type: IO_THREAD | SQL_THREAD
```

Stops the slave threads. `STOP SLAVE` requires the `SUPER` privilege.

Like `START SLAVE`, as of MySQL 4.0.2, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to stop.

This statement is called `SLAVE STOP` before MySQL 4.0.5. For the moment, `SLAVE STOP` is still accepted for backward compatibility, but is deprecated.

13.7. SQL Syntax for Prepared Statements

Support for server-side prepared statements was added in MySQL 4.1. This support takes advantage of the efficient client/server binary protocol, provided that you use an appropriate client programming interface. Candidate interfaces include the MySQL C API client library (for C programs), MySQL Connector/J (for Java programs), and MySQL Connector/NET. For example, the C API provides a set of function calls that make up its prepared statement API. See Section 24.2.4, “C API Prepared Statements”. Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library. (The `mysqli` extension in PHP 5.0 [<http://php.net/mysqli>] does this, for example.)

Beginning with MySQL 4.1.3, an alternative interface to prepared statements is available: SQL syntax for prepared statements. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that allows you to send SQL statements to the server to be executed, such as the **mysql** client program.
- You can use it even if the client is using an old version of the client library. The only requirement is that you be able to connect to a server that is recent enough to support SQL syntax for prepared statements.

SQL syntax for prepared statements is intended to be used for situations such as these:

- You may want to test how prepared statements work in your application before doing the application coding. Or perhaps an application has a problem executing prepared statements and you want to determine what the problem is interactively.
- You want to create a test case that describes a problem you are having with prepared statements, so that you can file a bug report.

- You need to use prepared statements but do not have access to a programming API that supports them.

SQL syntax for prepared statements is based on three SQL statements:

```
PREPARE stmt_name FROM preparable_stmt;  
EXECUTE stmt_name [USING @var_name [, @var_name] ...];  
{DEALLOCATE | DROP} PREPARE stmt_name;
```

The PREPARE statement prepares a statement and assigns it a name, *stmt_name*, by which to refer to the statement later. Statement names are not case sensitive. *preparable_stmt* is either a string literal or a user variable that contains the text of the statement. The text must represent a single SQL statement, not multiple statements. Within the statement, '?' characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The '?' characters should not be enclosed within quotes, even if you intend to bind them to string values.

If a prepared statement exists with the same name, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the client session within which it is created. Other clients cannot see it.

After preparing a statement, you execute it with an EXECUTE statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a USING clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the USING clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing it different variables or setting the variables to different values before each execution.

To deallocate a prepared statement, use the DEALLOCATE PREPARE statement. Attempting to execute a prepared statement after deallocating it results in an error.

If you terminate a client session without deallocating a previously prepared statement, the server deallocates it automatically.

The following statements can be used as prepared statements: CREATE TABLE, DELETE, DO, INSERT, REPLACE, SELECT, SET, UPDATE, and most SHOW statements. Other statements are not yet supported.

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';  
mysql> SET @a = 3;  
mysql> SET @b = 4;  
mysql> EXECUTE stmt1 USING @a, @b;  
+-----+  
| hypotenuse |  
+-----+  
|           5 |  
+-----+  
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement with a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          10 |
+-----+
mysql> DEALLOCATE PREPARE stmt2;
```

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to PREPARE cannot itself be a PREPARE, EXECUTE, or DEALLOCATE PREPARE statement.

Also, SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a PREPARE, EXECUTE, or DEALLOCATE PREPARE statement.

Chapter 14. MySQL Storage Engines and Table Types

MySQL supports several storage engines that act as handlers for different table types. MySQL storage engines include both those that handle transaction-safe tables and those that handle non-transaction-safe tables:

- The original storage engine was `ISAM`, which managed non-transactional tables. This engine has been replaced by `MyISAM` and should no longer be used. It is deprecated in MySQL 4.1, and is removed in MySQL 5.0.
- In MySQL 3.23.0, the `MyISAM` and `HEAP` storage engines were introduced. `MyISAM` is an improved replacement for `ISAM`. The `HEAP` storage engine provides in-memory tables. The `MERGE` storage engine was added in MySQL 3.23.25. It allows a collection of identical `MyISAM` tables to be handled as a single table. All three of these storage engines handle non-transactional tables, and all are included in MySQL by default. Note that the `HEAP` storage engine has been renamed the `MEMORY` engine.
- The `InnoDB` and `BDB` storage engines that handle transaction-safe tables were introduced in later versions of MySQL 3.23. Both are available in source distributions as of MySQL 3.23.34a. `BDB` is included in MySQL-Max binary distributions on those operating systems that support it. `InnoDB` also is included in MySQL-Max binary distributions for MySQL 3.23. Beginning with MySQL 4.0, `InnoDB` is included by default in all MySQL binary distributions. In source distributions, you can enable or disable either engine by configuring MySQL as you like.
- The `EXAMPLE` storage engine was added in MySQL 4.1.3. It is a ``stub" engine that does nothing. You can create tables with this engine, but no data can be stored into them or retrieved from them. The purpose of this engine is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.
- `NDB Cluster` is the storage engine used by MySQL Cluster to implement tables that are partitioned over many computers. It is available in source code distributions as of MySQL 4.1.2 and binary distributions as of MySQL-Max 4.1.3.
- The `ARCHIVE` storage engine was added in MySQL 4.1.3. It is used for storing large amounts of data without indexes in a very small footprint.
- The `CSV` storage engine was added in MySQL 4.1.4. This engine stores data in text files using comma-separated-values format.
- The `FEDERATED` storage engine was added in MySQL 5.0.3. This engine stores data in a remote database. In this release, it works with MySQL only, using the MySQL C Client API. Future releases will be able to connect to other data sources using other driver or client connection methods.

This chapter describes each of the MySQL storage engines except for `InnoDB` and `NDB Cluster`, which are covered in Chapter 15, *The InnoDB Storage Engine* and Chapter 16, *MySQL Cluster*.

When you create a new table, you can tell MySQL what type of table to create by adding an `ENGINE` or `TYPE` table option to the `CREATE TABLE` statement:

```
CREATE TABLE t (i INT) ENGINE = INNODB;  
CREATE TABLE t (i INT) TYPE = MEMORY;
```

`ENGINE` is the preferred term, but cannot be used before MySQL 4.0.18. `TYPE` is available beginning with MySQL 3.23.0, the first version of MySQL for which multiple storage engines were

available.

If you omit the `ENGINE` or `TYPE` option, the default storage engine is used. By default this is `MyISAM`. You can change it by using the `--default-storage-engine` or `--default-table-type` server startup option, or by setting the `storage_engine` or `table_type` system variable.

When MySQL is installed on Windows using the MySQL Configuration Wizard, the `InnoDB` storage engine is the default instead of `MyISAM`. See Section 2.3.5.1, “Introduction”.

To convert a table from one type to another, use an `ALTER TABLE` statement that indicates the new type:

```
ALTER TABLE t ENGINE = MYISAM;  
ALTER TABLE t TYPE = BDB;
```

See Section 13.2.5, “`CREATE TABLE` Syntax” and Section 13.2.2, “`ALTER TABLE` Syntax”.

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table of type `MyISAM`. This behavior is convenient when you want to copy tables between MySQL servers that support different storage engines. (For example, in a replication setup, perhaps your master server supports transactional storage engines for increased safety, but the slave servers use only non-transactional storage engines for greater speed.)

This automatic substitution of the `MyISAM` table type when an unavailable type is specified can be confusing for new MySQL users. In MySQL 4.1 and up, a warning is generated when a table type is automatically changed.

MySQL always creates an `.frm` file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the table type. The server creates the `.frm` file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage.

A database may contain tables of different types.

Transaction-safe tables (TSTs) have several advantages over non-transaction-safe tables (NTSTs):

- Safer. Even if MySQL crashes or you get hardware problems, you can get your data back, either by automatic recovery or from a backup plus the transaction log.
- You can combine many statements and accept them all at the same time with the `COMMIT` statement (if `autocommit` is disabled).
- You can execute `ROLLBACK` to ignore your changes (if `autocommit` is disabled).
- If an update fails, all of your changes are reverted. (With non-transaction-safe tables, all changes that have taken place are permanent.)
- Transaction-safe storage engines can provide better concurrency for tables that get many updates concurrently with reads.

Note that to use the `InnoDB` storage engine in MySQL 3.23, you must configure at least the `innodb_data_file_path` startup option. In 4.0 and up, `InnoDB` uses default configuration values if you specify none. See Section 15.4, “`InnoDB` Configuration”.

Non-transaction-safe tables have several advantages of their own, all of which occur because there is no transaction overhead:

- Much faster
- Lower disk space requirements

- Less memory required to perform updates

You can combine transaction-safe and non-transaction-safe tables in the same statements to get the best of both worlds. However, within a transaction with autocommit disabled, changes to non-transaction-safe tables still are committed immediately and cannot be rolled back.

14.1. The MyISAM Storage Engine

MyISAM is the default storage engine as of MySQL 3.23. It is based on the ISAM code but has many useful extensions.

Each MyISAM table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table definition. The data file has an `.MYD` (MYData) extension. The index file has an `.MYI` (MYIndex) extension,

To specify explicitly that you want a MyISAM table, indicate that with an `ENGINE` or `TYPE` table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;  
CREATE TABLE t (i INT) TYPE = MYISAM;
```

Normally, the `ENGINE` or `TYPE` option is unnecessary; MyISAM is the default storage engine unless the default has been changed.

You can check or repair MyISAM tables with the **myisamchk** utility. See Section 5.8.3.7, “Using **myisamchk** for Crash Recovery”. You can compress MyISAM tables with **myisampack** to take up much less space. See Section 8.2, “**myisampack**, the MySQL Compressed Read-only Table Generator”.

The following characteristics of the MyISAM storage engine are improvements over the older ISAM engine:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirement for binary portability is that the machine uses two's-complement signed integers (as every machine for the last 20 years has) and IEEE floating-point format (also totally dominant among mainstream machines). The only area of machines that may not support binary compatibility are embedded systems, which sometimes have peculiar processors.

There is no big speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it doesn't take that much more power to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- Large files (up to 63-bit file length) are supported on filesystems and operating systems that support large files.
- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- The maximum number of indexes per table is 64 (32 before MySQL 4.1.2). This can be changed by recompiling. The maximum number of columns per index is 16.
- The maximum key length is 1000 bytes (500 before MySQL 4.1.2). This can be changed by recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- BLOB and TEXT columns can be indexed.

- NULL values are allowed in indexed columns. This takes 0-1 bytes per key.
- All numeric key values are stored with the high byte first to allow better index compression.
- Index files are usually much smaller with MyISAM than with ISAM. This means that MyISAM normally uses less system resources than ISAM, but needs more CPU time when inserting data into a compressed index.
- When records are inserted in sorted order (as when you are using an AUTO_INCREMENT column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one AUTO_INCREMENT column per table. MyISAM automatically updates this column for INSERT/UPDATE. This makes AUTO_INCREMENT columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted as they are with ISAM. (When an AUTO_INCREMENT column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The AUTO_INCREMENT value can be reset with ALTER TABLE or **myisamchk**.
- If a table doesn't have free blocks in the middle of the data file, you can INSERT new rows into it at the same time that other threads are reading from the table. (These are known as concurrent inserts.) A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again.
- You can put the data file and index file on different directories to get more speed with the DATA DIRECTORY and INDEX DIRECTORY table options to CREATE TABLE. See Section 13.2.5, "CREATE TABLE Syntax".
- As of MySQL 4.1, each character column can have a different character set.
- There is a flag in the MyISAM index file that indicates whether the table was closed correctly. If **mysqld** is started with the `--myisam-recover` option, MyISAM tables are automatically checked when opened and repaired if the table wasn't closed properly.
- **myisamchk** marks tables as checked if you run it with the `--update-state` option. **myisamchk --fast** checks only those tables that don't have this mark.
- **myisamchk --analyze** stores statistics for key parts, not only for whole keys as in ISAM.
- **myisampack** can pack BLOB and VARCHAR columns; **pack_isam** cannot.

MyISAM also supports the following features, which MySQL will be able to use in the near future:

- Support for a true VARCHAR type; a VARCHAR column starts with a length stored in two bytes.
- Tables with VARCHAR may have fixed or dynamic record length.
- VARCHAR and CHAR columns may be up to 64KB.
- A hashed computed index can be used for UNIQUE. This allows you to have UNIQUE on any combination of columns in a table. (You can't search on a UNIQUE computed index, however.)

14.1.1. MyISAM Startup Options

The following options to **mysqld** can be used to change the behavior of MyISAM tables:

- `--myisam-recover=mode`

Set the mode for automatic recovery of crashed MyISAM tables.

- `--delay-key-write=ALL`

Don't flush key buffers between writes for any MyISAM table.

Note: If you do this, you should not use MyISAM tables from another program (such as from another MySQL server or with `myisamchk`) when the table is in use. Doing so leads to index corruption.

Using `--external-locking` does not help for tables that use `--delay-key-write`.

See Section 5.3.1, “`mysqld` Command-Line Options”.

The following system variables affect the behavior of MyISAM tables:

- `bulk_insert_buffer_size`

The size of the tree cache used in bulk insert optimization. **Note:** This is a limit *per thread*!

- `myisam_max_extra_sort_file_size`

Used to help MySQL to decide when to use the slow but safe key cache index creation method. **Note:** This parameter is given in megabytes before MySQL 4.0.3, and in bytes as of 4.0.3. This flag was removed in MySQL 5.0.6.

- `myisam_max_sort_file_size`

Don't use the fast sort index method to create an index if the temporary file would become larger than this. **Note:** This parameter is given in megabytes before MySQL 4.0.3, and in bytes as of 4.0.3.

- `myisam_sort_buffer_size`

Set the size of the buffer used when recovering tables.

See Section 5.3.3, “Server System Variables”.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover` option. In this case, when the server opens a MyISAM table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with `--skip-external-locking`. If either of these conditions is true, the following happens:

- The table is checked for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from a previous completed statement and you didn't specify `FORCE` in the value of the `--myisam-recover` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

Note that if the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

14.1.2. Space Needed for Keys

MyISAM tables use B-tree indexes. You can roughly calculate the size for the index file as $(key_length+4)/0.67$, summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if the string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In MyISAM tables, you can also prefix compress numbers by specifying `PACK_KEYS=1` when you create the table. This helps when you have many integer keys that have an identical prefix when the numbers are stored high-byte first.

14.1.3. MyISAM Table Storage Formats

MyISAM supports three different storage formats. Two of them (fixed and dynamic format) are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility.

When you `CREATE` or `ALTER` a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option. This causes `CHAR` and `VARCHAR` columns to become `CHAR` for `FIXED` format or `VARCHAR` for `DYNAMIC` format.

In the future, you will be able to compress or decompress tables by specifying `ROW_FORMAT={COMPRESSED | DEFAULT}` to `ALTER TABLE`. See Section 13.2.5, “CREATE TABLE Syntax”.

14.1.3.1. Static (Fixed-Length) Table Characteristics

Static format is the default for MyISAM tables. It is used when the table contains no variable-length columns (`VARCHAR`, `BLOB`, or `TEXT`). Each row is stored using a fixed number of bytes.

Of the three MyISAM storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats. The speed comes from the easy way that rows in the data file can be found on disk: When looking up a row based on a row number in the index, multiply the row number by the row length. Also, when scanning a table, it is very easy to read a constant number of records with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format MyISAM file. In this case, `myisamchk` can easily determine where each row starts and ends, so it can usually reclaim all records except the partially written one. Note that MyISAM table indexes can always be reconstructed based on the data rows.

General characteristics of static format tables:

- `CHAR` columns are space-padded to the column width. This is also true for `NUMERIC`, and

DECIMAL columns created before MySQL 5.0.3.

- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because records are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of records and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or **myisamchk -r**.
- Usually require more disk space than for dynamic-format tables.

14.1.3.2. Dynamic Table Characteristics

Dynamic storage format is used if a MyISAM table contains any variable-length columns (VARCHAR, BLOB, or TEXT), or if the table was created with the `ROW_FORMAT=DYNAMIC` option.

This format is a little more complex because each row has a header that indicates how long it is. One record can also end up at more than one location when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or **myisamchk** to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

General characteristics of dynamic-format tables:

- All string columns are dynamic except those with a length less than four.
- Each record is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). Note that this does not include columns that contain NULL values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Non-empty strings are saved as a length byte plus the string contents.
- Much less disk space usually is required than for fixed-length tables.
- Each record uses only as much space as is required. However, if a record becomes larger, it is split into as many pieces as are required, resulting in record fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or **myisamchk -r** from time to time to get better performance. Use **myisamchk -ei** to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because a record may be fragmented into many pieces and a link (fragment) may be missing.
- The expected row length for dynamic-sized records is calculated using the following expression:

$$\begin{aligned} &3 \\ &+ (\textit{number of columns} + 7) / 8 \\ &+ (\textit{number of char columns}) \\ &+ (\textit{packed size of numeric columns}) \\ &+ (\textit{length of strings}) \\ &+ (\textit{number of NULL columns} + 7) / 8 \end{aligned}$$

There is a penalty of 6 bytes for each link. A dynamic record is linked whenever an update causes an enlargement of the record. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, there is another link. You may check how many links there are with **myisamchk -ed**. All links may be removed with **myisamchk -r**.

14.1.3.3. Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the **myisampack** tool.

All MySQL distributions as of version 3.23.19 include **myisampack** by default. (This version is when MySQL was placed under the GPL.) For earlier versions, **myisampack** was included only with licenses or support agreements, but the server still can read tables that were compressed with **myisampack**. Compressed tables can be uncompressed with **myisamchk**. (For the **ISAM** storage engine, compressed tables can be created with **pack_isam** and uncompressed with **isamchk**.)

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is very nice when using slow disks (such as CD-ROMs).
- Each record is compressed separately, so there is very little access overhead. The header for a record is fixed (1-3 bytes) depending on the biggest record in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
 - Suffix space compression.
 - Prefix space compression.
 - Numbers with a value of zero are stored using one bit.
 - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a **BIGINT** column (eight bytes) can be stored as a **TINYINT** column (one byte) if all its values are in the range from -128 to 127.
 - If a column has only a small set of possible values, the column type is converted to **ENUM**.
 - A column may use a combination of the preceding compressions.
- Can handle fixed-length or dynamic-length records.

14.1.4. MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted.

14.1.4.1. Corrupted MyISAM Tables

Even though the **MyISAM** table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if some of the following things happen:

- The **mysqld** process is killed in the middle of a write.
- Unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware errors.
- You are using an external program (such as **myisamchk**) on a table that is being modified by the server at the same time.
- A software bug in the MySQL or **MyISAM** code.

Typical symptoms for a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete data.

You can check whether a MyISAM table is okay with the `CHECK TABLE` statement. You can repair a corrupted MyISAM table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See Section 13.5.2.3, “`CHECK TABLE` Syntax”, Section 13.5.2.6, “`REPAIR TABLE` Syntax”, and Section 5.8.3.1, “`myisamchk` Invocation Syntax”.

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation, which is a bug. You should try to create a reproducible test case that demonstrates the problem. See Section A.4.2, “What to Do If MySQL Keeps Crashing” and Section E.1.6, “Making a Test Case If You Experience Table Corruption”.

14.1.4.2. Problems from Tables Not Being Closed Properly

Each MyISAM index (`.MYI`) file has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table to verify that it's okay.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because of a `FLUSH TABLES` operation or because there isn't room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can go out of sync only under these conditions:

- The MyISAM tables are copied without a preceding `LOCK TABLES` and `FLUSH TABLES`.
- MySQL has crashed between an update and the final close. (Note that the table may still be okay, because MySQL always issues writes for everything between each statement.)
- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.

- Many **mysqld** servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not signaled to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See Section 5.11, “Running Multiple MySQL Servers on the Same Machine” for additional discussion.

14.2. The MERGE Storage Engine

The `MERGE` storage engine was introduced in MySQL 3.23.25. It is also known as the `MRG_MyISAM` engine.

A `MERGE` table is a collection of identical `MyISAM` tables that can be used as one. “Identical” means that all tables have identical column and index information. You can’t merge tables in which the columns are listed in a different order, don’t have exactly the same columns, or have the indexes in different order. However, any or all of the tables can be compressed with **mysampack**. See Section 8.2, “**mysampack**, the MySQL Compressed Read-only Table Generator”. Differences in table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` do not matter.

When you create a `MERGE` table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table definition, and an `.MRG` file contains the names of the tables that should be used as one. (Originally, all used tables had to be in the same database as the `MERGE` table itself. This restriction has been lifted as of MySQL 4.1.1.)

You can use `SELECT`, `DELETE`, `UPDATE`, and (as of MySQL 4.0) `INSERT` on the collection of tables. For the moment, you must have `SELECT`, `UPDATE`, and `DELETE` privileges on the tables that you map to a `MERGE` table.

If you `DROP` the `MERGE` table, you are dropping only the `MERGE` specification. The underlying tables are not affected.

When you create a `MERGE` table, you must specify a `UNION=(list-of-tables)` clause that indicates which tables you want to use as one. You can optionally specify an `INSERT_METHOD` option if you want inserts for the `MERGE` table to happen in the first or last table of the `UNION` list. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table. If you don’t specify any `INSERT_METHOD` option or specify it with a value of `NO`, attempts to insert records into the `MERGE` table result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (  
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
->   message CHAR(20));  
mysql> CREATE TABLE t2 (  
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
->   message CHAR(20));  
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');  
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');  
mysql> CREATE TABLE total (  
->   a INT NOT NULL AUTO_INCREMENT,  
->   message CHAR(20), INDEX(a))  
->   TYPE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Note that the `a` column is indexed in the `MERGE` table, but is not declared as a `PRIMARY KEY` as it is in the underlying `MyISAM` tables. This is necessary because a `MERGE` table cannot enforce uniqueness over the set of underlying tables.

After creating the `MERGE` table, you can do things like this:

```
mysql> SELECT * FROM total;
+----+-----+
| a  | message |
+----+-----+
| 1  | Testing |
| 2  | table   |
| 3  | t1      |
| 1  | Testing |
| 2  | table   |
| 3  | t2      |
+----+-----+
```

Note that you can also manipulate the .MRG file directly from outside of the MySQL server:

```
shell> cd /mysql-data-directory/current-database
shell> ls -l t1 t2 > total.MRG
shell> mysqladmin flush-tables
```

To remap a MERGE table to a different collection of MyISAM tables, you can do one of the following:

- DROP the table and re-create it.
- Use ALTER TABLE *tbl_name* UNION=(. . .) to change the list of underlying tables.
- Change the .MRG file and issue a FLUSH TABLE statement for the MERGE table and all underlying tables to force the storage engine to read the new definition file.

MERGE tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with **myisampack**, and then create a MERGE table to use them as one.
- Obtain more speed. You can split a big read-only table based on some criteria, and then put individual tables on different disks. A MERGE table on this could be much faster than using the big table.
- Do more efficient searches. If you know exactly what you are looking for, you can search in just one of the split tables for some queries and use a MERGE table for others. You can even have many different MERGE tables that use overlapping sets of tables.
- Do more efficient repairs. It's easier to repair the individual tables that are mapped to a MERGE table than to repair a single really big table.
- Instantly map many tables as one. A MERGE table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, MERGE table collections are *very* fast to create or remap. (Note that you must still specify the index definitions when you create a MERGE table, even though no indexes are created.)
- If you have a set of tables that you join as a big table on demand or batch, you should instead create a MERGE table on them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each MyISAM table is bound by this limit, but a collection of MyISAM tables is not.
- You can create an alias or synonym for a MyISAM table by defining a MERGE table that maps to that single table. There should be no really notable performance impact of doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of MERGE tables are:

- You can use only identical MyISAM tables for a MERGE table.
- MERGE tables use more file descriptors. If 10 clients are using a MERGE table that maps to 10 tables, the server uses $(10*10) + 10$ file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Key reads are slower. When you read a key, the MERGE storage engine needs to issue a read on all underlying tables to check which one most closely matches the given key. If you then do a ``read-next," the MERGE storage engine needs to search the read buffers to find the next key. Only when one key buffer is used up, the storage engine needs to read the next key block. This makes MERGE keys much slower on `eq_ref` searches, but not much slower on `ref` searches. See Section 7.2.1, "EXPLAIN Syntax (Get Information About a SELECT)" for more information about `eq_ref` and `ref`.

14.2.1. MERGE Table Problems

The following are the known problems with MERGE tables:

- If you use `ALTER TABLE` to change a MERGE table to another table type, the mapping to the underlying tables is lost. Instead, the rows from the underlying MyISAM tables are copied into the altered table, which then is assigned the new type.
- Before MySQL 4.1.1, all underlying tables and the MERGE table itself had to be in the same database.
- `REPLACE` doesn't work.
- You can't use `DROP TABLE`, `ALTER TABLE`, `DELETE FROM` without a `WHERE` clause, `REPAIR TABLE`, `TRUNCATE TABLE`, `OPTIMIZE TABLE`, or `ANALYZE TABLE` on any of the tables that are mapped into a MERGE table that is ``open." If you do this, the MERGE table may still refer to the original table and you get unexpected results. The easiest way to work around this deficiency is to issue a `FLUSH TABLES` statement to ensure that no MERGE tables remain ``open."
- A MERGE table cannot maintain `UNIQUE` constraints over the whole table. When you perform an `INSERT`, the data goes into the first or last MyISAM table (depending on the value of the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that MyISAM table, but not across all the tables in the collection.
- Before MySQL 3.23.49, `DELETE FROM merge_table` used without a `WHERE` clause only clears the mapping for the table. That is, it incorrectly empties the `.MRG` file rather than deleting records from the mapped tables.
- Using `RENAME TABLE` on an active MERGE table may corrupt the table. This is fixed in MySQL 4.1.x.
- When you create a MERGE table, there is no check whether the underlying tables exist and have identical structure. When the MERGE table is used, MySQL does a quick check that the record length for all mapped tables is equal, but this is not foolproof. If you create a MERGE table from dissimilar MyISAM tables, you are very likely to run into strange problems.
- Index order in the MERGE table and its underlying tables should be the same. If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a MERGE table, and then use `ALTER TABLE` to add a non-unique index on the MERGE table, the index order is different for the tables if there was an old non-unique index in the underlying table. (This is because `ALTER TABLE` puts `UNIQUE` indexes before non-unique indexes to be able to detect duplicate keys as early as possible.) Consequently, queries may return unexpected results.

- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine does the table mapping hidden from the upper layer of MySQL. Because Windows doesn't allow you to delete files that are open, you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.

14.3. The MEMORY (HEAP) Storage Engine

The `MEMORY` storage engine creates tables with contents that are stored in memory. Before MySQL 4.1, `MEMORY` tables are called `HEAP` tables. As of 4.1, `MEMORY` is the preferred term, and `HEAP` is a synonym for `MEMORY`.

Each `MEMORY` table is associated with one disk file. The filename begins with the table name and has an extension of `.frm` to indicate that it stores the table definition.

To specify explicitly that you want a `MEMORY` table, indicate that with an `ENGINE` or `TYPE` table option:

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
CREATE TABLE t (i INT) TYPE = HEAP;
```

`MEMORY` tables are stored in memory and use hash indexes by default. This makes them very fast, and very useful for creating temporary tables. However, when the server shuts down, all data stored in `MEMORY` tables is lost. The tables continue to exist because their definitions are stored in the `.frm` files on disk, but their contents are empty when the server restarts.

Here is an example that shows how you might create, use, and remove a `MEMORY` table:

```
mysql> CREATE TABLE test TYPE=MEMORY
->     SELECT ip,SUM(downloads) AS down
->     FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

`MEMORY` tables have the following characteristics:

- Space for `MEMORY` tables is allocated in small blocks. The tables use 100% dynamic hashing (on inserting). No overflow areas and no extra key space are needed. There is no extra space needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. `MEMORY` tables also don't have problems with deletes plus inserts, which is common with hashed tables.
- `MEMORY` tables allow up to 32 indexes per table, 16 columns per index, and a maximum key length of 500 bytes.
- Before MySQL 4.1, the `MEMORY` storage engine implements only hash indexes. From MySQL 4.1 on, hash indexes are still the default, but you can specify explicitly that a `MEMORY` table index should be a `HASH` or `BTREE` by adding a `USING` clause:

```
CREATE TABLE lookup
  (id INT, INDEX USING HASH (id))
  ENGINE = MEMORY;
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
  ENGINE = MEMORY;
```

General characteristics of B-tree and hash indexes are described in Section 7.4.5, “How MySQL Uses Indexes”.

- You can have non-unique keys in a `MEMORY` table. (This is an uncommon feature for imple-

mentations of hash indexes.)

- As of MySQL 4.1, you can use `INSERT DELAYED` with `MEMORY` tables. See Section 13.1.4.2, “`INSERT DELAYED` Syntax”.
- If you have a hash index on a `MEMORY` table that has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a `BTREE` index to avoid this problem.
- `MEMORY` tables use a fixed record length format.
- `MEMORY` doesn't support `BLOB` or `TEXT` columns.
- `MEMORY` doesn't support `AUTO_INCREMENT` columns before MySQL 4.1.0.
- Prior to MySQL 4.0.2, `MEMORY` doesn't support indexes on columns that can contain `NULL` values.
- `MEMORY` tables are shared between all clients (just like any other non-`TEMPORARY` table).
- `MEMORY` table contents are stored in memory, which is a property that `MEMORY` tables share with internal tables that the server creates on the fly while processing queries. However, the two types of tables differ in that `MEMORY` tables are not subject to storage conversion, whereas internal tables are:
 - If an internal table becomes too large, the server automatically converts it to an on-disk table. The size limit is determined by the value of the `tmp_table_size` system variable.
 - `MEMORY` tables are never converted to disk tables. To ensure that you don't accidentally do anything foolish, you can set the `max_heap_table_size` system variable to impose a maximum size on `MEMORY` tables. For individual tables, you can also specify a `MAX_ROWS` table option in the `CREATE TABLE` statement.
- The server needs enough extra memory to maintain all `MEMORY` tables that are in use at the same time.
- To free memory used by a `MEMORY` table if you no longer require its contents, you should execute `DELETE` or `TRUNCATE TABLE`, or else remove the table with `DROP TABLE`.
- If you want to populate a `MEMORY` table when the MySQL server starts, you can use the `--init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into the file to load the table from some persistent data source. See Section 5.3.1, “`mysqld` Command-Line Options”.
- If you are using replication, the master server's `MEMORY` tables become empty when it is shut down and restarted. However, a slave is not aware that these tables have become empty, so it returns out-of-date content if you select data from them. Beginning with MySQL 4.0.18, when a `MEMORY` table is used on the master for the first time since the master's startup, a `DELETE FROM` statement is written to the master's binary log automatically, thus synchronizing the slave to the master again. Note that even with this strategy, the slave still has out-of-date data in the table during the interval between the master's restart and its first use of the table. But if you use the `--init-file` option to populate the `MEMORY` table on the master at startup, it ensures that the failing time interval is zero.
- The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

14.4. The BDB (BerkeleyDB) Storage Engine

Sleepycat Software has provided MySQL with the Berkeley DB transactional storage engine. This storage engine typically is called BDB for short. Support for the BDB storage engine is included in MySQL source distributions starting from version 3.23.34a and is activated in MySQL-Max binary distributions.

BDB tables may have a greater chance of surviving crashes and are also capable of `COMMIT` and `ROLLBACK` operations on transactions. The MySQL source distribution comes with a BDB distribution that has a couple of small patches to make it work more smoothly with MySQL. You can't use a non-patched BDB version with MySQL.

We at MySQL AB are working in close cooperation with Sleepycat to keep the quality of the MySQL/BDB interface high. (Even though Berkeley DB is in itself very tested and reliable, the MySQL interface is still considered gamma quality. We are improving and optimizing it.)

When it comes to support for any problems involving BDB tables, we are committed to helping our users locate the problem and create a reproducible test case. Any such test case is forwarded to Sleepycat, which in turn helps us find and fix the problem. As this is a two-stage operation, any problems with BDB tables may take a little longer for us to fix than for other storage engines. However, we anticipate no significant difficulties with this procedure because the Berkeley DB code itself is used in many applications other than MySQL.

For general information about Berkeley DB, please visit the Sleepycat Web site, <http://www.sleepycat.com/>.

14.4.1. Operating Systems Supported by BDB

Currently, we know that the BDB storage engine works with the following operating systems:

- Linux 2.x Intel
- Sun Solaris (SPARC and x86)
- FreeBSD 4.x/5.x (x86, sparc64)
- IBM AIX 4.3.x
- SCO OpenServer
- SCO UnixWare 7.1.x

BDB does not work with the following operating systems:

- Linux 2.x Alpha
- Linux 2.x AMD64
- Linux 2.x IA-64
- Linux 2.x s390
- Mac OS X

Note: The preceding lists are not complete. We update them as we receive more information.

If you build MySQL from source with support for BDB tables, but the following error occurs when you start **mysqld**, it means BDB is not supported for your architecture:

```
bdb: architecture lacks fast mutexes: applications cannot be threaded
Can't init databases
```

In this case, you must rebuild MySQL without BDB table support or start the server with the `--skip-bdb` option.

14.4.2. Installing BDB

If you have downloaded a binary version of MySQL that includes support for Berkeley DB, simply follow the usual binary distribution installation instructions. (MySQL-Max distributions include BDB support.)

If you build MySQL from source, you can enable BDB support by running **configure** with the `--with-berkeley-db` option in addition to any other options that you normally use. Download a distribution for MySQL 3.23.34 or newer, change location into its top-level directory, and run this command:

```
shell> ./configure --with-berkeley-db [other-options]
```

For more information, see Section 2.7, “Installing MySQL on Other Unix-Like Systems”, Section 5.1.2, “The **mysqld-max** Extended MySQL Server”, and See Section 2.8, “MySQL Installation Using a Source Distribution”.

14.4.3. BDB Startup Options

The following options to **mysqld** can be used to change the behavior of the BDB storage engine:

- `--bdb-home=path`

The base directory for BDB tables. This should be the same directory you use for `--datadir`.

- `--bdb-lock-detect=method`

The BDB lock detection method. The option value should be `DEFAULT`, `OLDEST`, `RANDOM`, or `YOUNGEST`.

- `--bdb-logdir=path`

The BDB log file directory.

- `--bdb-no-recover`

Don't start Berkeley DB in recover mode.

- `--bdb-no-sync`

Don't synchronously flush the BDB logs.

- `--bdb-shared-data`

Start Berkeley DB in multi-process mode. (Don't use `DB_PRIVATE` when initializing Berkeley DB.)

- `--bdb-tmpdir=path`

The BDB temporary file directory.

- `--skip-bdb`

Disable the BDB storage engine.

See Section 5.3.1, “**mysqld** Command-Line Options”.

The following system variable affects the behavior of BDB tables:

- `bdb_max_lock`

The maximum number of locks you can have active on a BDB table.

See Section 5.3.3, “Server System Variables”.

If you use the `--skip-bdb` option, MySQL does not initialize the Berkeley DB library and this saves a lot of memory. However, if you use this option, you cannot use BDB tables. If you try to create a BDB table, MySQL creates a MyISAM table instead.

Normally, you should start **mysqld** without the `--bdb-no-recover` option if you intend to use BDB tables. However, this may give you problems when you try to start **mysqld** if the BDB log files are corrupted. See Section 2.9.2.3, “Starting and Troubleshooting the MySQL Server”.

With the `bdb_max_lock` variable, you can specify the maximum number of locks that can be active on a BDB table. The default is 10,000. You should increase this if errors such as the following occur when you perform long transactions or when **mysqld** has to examine many rows to execute a query:

```
bdb: Lock table is out of available locks
Got error 12 from ...
```

You may also want to change the `binlog_cache_size` and `max_binlog_cache_size` variables if you are using large multiple-statement transactions. See Section 5.10.4, “The Binary Log”.

14.4.4. Characteristics of BDB Tables

Each BDB table is stored on disk in two files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table definition, and a `.db` file contains the table data and indexes.

To specify explicitly that you want a BDB table, indicate that with an `ENGINE` or `TYPE` table option:

```
CREATE TABLE t (i INT) ENGINE = BDB;
CREATE TABLE t (i INT) TYPE = BDB;
```

BerkeleyDB is a synonym for BDB in the `ENGINE` or `TYPE` option.

The BDB storage engine provides transactional tables. The way you use these tables depends on the autocommit mode:

- If you are running with autocommit enabled (which is the default), changes to BDB tables are committed immediately and cannot be rolled back.
- If you are running with autocommit disabled, changes do not become permanent until you ex-

ecute a `COMMIT` statement. Instead of committing, you can execute `ROLLBACK` to forget the changes.

You can start a transaction with the `BEGIN WORK` statement to suspend autocommit, or with `SET AUTOCOMMIT=0` to disable autocommit explicitly.

See Section 13.4.1, “`START TRANSACTION`, `COMMIT`, and `ROLLBACK` Syntax”.

The BDB storage engine has the following characteristics:

- BDB tables can have up to 31 indexes per table, 16 columns per index, and a maximum key size of 1024 bytes (500 bytes before MySQL 4.0).
- MySQL requires a `PRIMARY KEY` in each BDB table so that each row can be uniquely identified. If you don't create one explicitly, MySQL creates and maintains a hidden `PRIMARY KEY` for you. The hidden key has a length of five bytes and is incremented for each insert attempt.
- The `PRIMARY KEY` is faster than any other index, because the `PRIMARY KEY` is stored together with the row data. The other indexes are stored as the key data + the `PRIMARY KEY`, so it's important to keep the `PRIMARY KEY` as short as possible to save disk space and get better speed.

This behavior is similar to that of `InnoDB`, where shorter primary keys save space not only in the primary index but in secondary indexes as well.

- If all columns you access in a BDB table are part of the same index or part of the primary key, MySQL can execute the query without having to access the actual row. In a `MyISAM` table, this can be done only if the columns are part of the same index.
- Sequential scanning is slower than for `MyISAM` tables because the data in BDB tables is stored in B-trees and not in a separate data file.
- Key values are not prefix- or suffix-compressed like key values in `MyISAM` tables. In other words, key information takes a little more space in BDB tables compared to `MyISAM` tables.
- There are often holes in the BDB table to allow you to insert new rows in the middle of the index tree. This makes BDB tables somewhat larger than `MyISAM` tables.
- `SELECT COUNT(*) FROM tbl_name` is slow for BDB tables, because no row count is maintained in the table.
- The optimizer needs to know the approximate number of rows in the table. MySQL solves this by counting inserts and maintaining this in a separate segment in each BDB table. If you don't issue a lot of `DELETE` or `ROLLBACK` statements, this number should be accurate enough for the MySQL optimizer. However, MySQL stores the number only on close, so it may be incorrect if the server terminates unexpectedly. It should not be fatal even if this number is not 100% correct. You can update the row count by using `ANALYZE TABLE` or `OPTIMIZE TABLE`. See Section 13.5.2.1, “`ANALYZE TABLE` Syntax” and Section 13.5.2.5, “`OPTIMIZE TABLE` Syntax”.
- Internal locking in BDB tables is done at the page level.
- `LOCK TABLES` works on BDB tables as with other tables. If you don't use `LOCK TABLE`, MySQL issues an internal multiple-write lock on the table (a lock that doesn't block other writers) to ensure that the table is properly locked if another thread issues a table lock.
- To be able to roll back transactions, the BDB storage engine maintains log files. For maximum performance, you can use the `--bdb-logdir` option to place the BDB logs on a different disk than the one where your databases are located.
- MySQL performs a checkpoint each time a new BDB log file is started, and removes any BDB log files that are not needed for current transactions. You can also use `FLUSH LOGS` at any

time to checkpoint the Berkeley DB tables.

For disaster recovery, you should use table backups plus MySQL's binary log. See Section 5.8.1, "Database Backups".

Warning: If you delete old log files that are still in use, BDB is not able to do recovery at all and you may lose data if something goes wrong.

- Applications must always be prepared to handle cases where any change of a BDB table may cause an automatic rollback and any read may fail with a deadlock error.
- If you get full disk with a BDB table, you get an error (probably error 28) and the transaction should roll back. This contrasts with MyISAM and ISAM tables, for which **mysqld** waits for enough free disk before continuing.

14.4.5. Things We Need to Fix for BDB

- It's very slow to open many BDB tables at the same time. If you are going to use BDB tables, you should not have a very large table cache (for example, with a size larger than 256) and you should use the `--no-auto-rehash` option when you use the **mysql** client. We plan to partly fix this in 4.0.
- `SHOW TABLE STATUS` doesn't yet provide very much information for BDB tables.
- Optimize performance.
- Change to not use page locks at all for table scanning operations.

14.4.6. Restrictions on BDB Tables

The following list indicates restrictions that you must observe when using BDB tables:

- Each BDB table stores in the `.db` file the path to the file as it was created. This was done to be able to detect locks in a multi-user environment that supports symlinks. However, the consequence is that BDB table files cannot be moved from one database directory to another.
- When making backups of BDB tables, you must either use **mysqldump** or else make a backup that includes the files for each BDB table (the `.frm` and `.db` files) as well as the BDB log files. The BDB storage engine stores unfinished transactions in its log files and requires them to be present when **mysqld** starts. The BDB logs are the files in the data directory with names of the form `log.XXXXXXXXXX` (ten digits).
- If a column that allows NULL values has a unique index, only a single NULL value is allowed. This differs from other storage engines.

14.4.7. Errors That May Occur When Using BDB Tables

- If the following error occurs when you start **mysqld**, it means that the new BDB version doesn't support the old log file format:

```
bdb: Ignoring log file: ../log.XXXXXXXXXX:
unsupported log version #
```

In this case, you must delete all BDB logs from your data directory (the files with names that have the format `log.XXXXXXXXXX`) and restart **mysqld**. We also recommend that you then

use `mysqldump --opt` to dump your BDB tables, drop the tables, and restore them from the dump file.

- If autocommit mode is disabled and you drop a BDB table that is referenced in another transaction, you may get error messages of the following form in your MySQL error log:

```
001119 23:43:56 bdb: Missing log fileid entry
001119 23:43:56 bdb: txn_abort: Log undo failed for LSN:
                    1 3644744: Invalid
```

This is not fatal, but until the problem is fixed, we recommend that you not drop BDB tables except while autocommit mode is enabled. (The fix is not trivial.)

14.5. The `EXAMPLE` Storage Engine

The `EXAMPLE` storage engine was added in MySQL 4.1.3. It is a “stub” engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To examine the source for the `EXAMPLE` engine, look in the `sql/examples` directory of a source distribution for MySQL 4.1.3 or newer.

To enable this storage engine, use the `--with-example-storage-engine` option to **configure** when you build MySQL.

When you create an `EXAMPLE` table, the server creates a table definition file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table or retrieved from it.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

14.6. The `FEDERATED` Storage Engine

The `FEDERATED` storage engine was added in MySQL 5.0.3. It is a storage engine that accesses data in tables of remote databases rather than in local tables.

To examine the source for the `FEDERATED` engine, look in the `sql` directory of a source distribution for MySQL 5.0.3 or newer.

14.6.1. Installing the `FEDERATED` Storage Engine

To enable this storage engine, use the `--with-federated-storage-engine` option to **configure** when you build MySQL.

14.6.2. Description of the `FEDERATED` Storage Engine

When you create a `FEDERATED` table, the server creates a table definition file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created, because the actual data is in a remote database. This differs from the way that storage engines for

local tables work.

For local database tables, data files are local. For example, if you create a MyISAM table named `users`, the MyISAM handler creates a data file named `users.MYD`. A handler for local tables reads, inserts, deletes, and updates data in local data files, and records are stored in a format particular to the handler. To read records, the handler must parse data into columns. To write records, column values must be converted to the row format used by the handler and written to the local data file.

With the MySQL FEDERATED storage engine, there are no local data files for a table (for example, there is no `.MYD` file). Instead, a remote database stores the data that normally would be in the table. This necessitates the use of the MySQL client API to read, delete, update, and insert data. Data retrieval is initiated via a `SELECT * FROM tbl_name` SQL statement. To read the result, rows are fetched one at a time by using the `mysql_fetch_row()` C API function, and then converted from the columns in the `SELECT` result set to the format that the FEDERATED handler expects.

The basic flow is as follows:

1. SQL calls issues locally
2. MySQL handler API (data in handler format)
3. MySQL client API (data converted to SQL calls)
4. Remote database -> MySQL client API
5. Convert result sets (if any) to handler format
6. Handler API -> Result rows or rows-affected count to local

14.6.3. How to use FEDERATED Tables

The procedure for using FEDERATED tables is very simple. Normally, you have two servers running, either both on the same host or on different hosts. (It is also possible for a FEDERATED table to use another table that is managed by the same server, though there is little point in doing so.)

First, you must have a table on the remote server that you want to access with the FEDERATED table. Suppose that the remote table is in the `federated` database and is defined like this:

```
CREATE TABLE test_table (  
    id      int(20) NOT NULL auto_increment,  
    name   varchar(32) NOT NULL default '',  
    other  int(20) NOT NULL default '0',  
    PRIMARY KEY (id),  
    KEY name (name),  
    KEY other_key (other)  
)  
ENGINE=MyISAM  
DEFAULT CHARSET=latin1;
```

The `ENGINE` table option could name any storage engine; the table need not be a MyISAM table.

Next, create a FEDERATED table for accessing the remote table. The server where you create the FEDERATED table is the "client server." On this server, create the table as follows:

```
CREATE TABLE federated_table (  
    id      int(20) NOT NULL auto_increment,  
    name   varchar(32) NOT NULL default '',  
    other  int(20) NOT NULL default '0',  
    PRIMARY KEY (id),  
    KEY name (name),  
    KEY other_key (other)  
)
```

```
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
COMMENT='mysql://root@remote_host:9306/federated/test_table';
```

The structure of this table must be exactly the same as the remote table, except that the `ENGINE` table option should be `FEDERATED` and the `COMMENT` table option is a connection string that indicates to the `FEDERATED` engine how to connect to the remote server.

The `FEDERATED` engine creates only the `test_table.frm` file in the federated database.

The remote host information indicates the remote server to which your "client" server connects, and the database and table information indicates which remote table to use as the "data file." In the example, the remote server is indicated to be running as `remote_host` on port 9306, so you want to start that server so that it is indeed listening to port 9306.

The general form of the connection string in the `COMMENT` option is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Only `mysql` is supported as the `scheme` at this point, and the password and port number are optional.

Here are some example connection strings:

```
COMMENT='mysql://username:password@hostname:port/database/tablename'
COMMENT='mysql://username@hostname/database/tablename'
COMMENT='mysql://username:password@hostname/database/tablename'
```

The use of `COMMENT` for specifying the connection string is non-optimal and will likely change in MySQL 5.1. Keep this in mind when you use `FEDERATED` tables, because it means you'll need to make some modifications when that happens.

Also, because a password is stored in the connection string as plain text, it can be seen by any user who can use `SHOW CREATE TABLE` or `SHOW TABLE STATUS` for the `FEDERATED` table, or query the `TABLES` table of `INFORMATION_SCHEMA`.

14.6.4. Limitations of the `FEDERATED` Storage Engine

What the `FEDERATED` storage engine does and doesn't support:

- In the first version, the remote server must be a MySQL server. Support by `FEDERATED` for other database engines may be added in the future.
- The remote table that a `FEDERATED` table points to *must* exist before you try to access the table through the `FEDERATED` table.
- It is possible for one `FEDERATED` table to point to another, but you must be careful not to create a loop. You know and have heard the screeching of audio feedback? You know what you see visually when you place two mirrors in front of each other, how the reflection continues for eternity? Well, need we say more?!
- There is no support for transactions.
- There is no way for the `FEDERATED` engine to know if the remote table has changed. The reason for this is that this table has to work like a data file that would never be written to by anything other than the database. The integrity of the data in the local table could be breached if there was any change to the remote database.
- The `FEDERATED` storage engine supports `SELECT`, `INSERT`, `UPDATE`, `DELETE`, and indexes. It does not support `ALTER TABLE`, `DROP TABLE`, or any other Data Definition Language

statements. The first implementation does not use Prepared statements. It remains to be seen whether the limited subset of the client API for the server supports this capability.

- The implementation uses `SELECT`, `INSERT`, `UPDATE`, `DELETE` and not `HANDLER`.
- `FEDERATED` tables do not work with the query cache.

Some of these limitations may be lifted in future versions of the `FEDERATED` handler.

14.7. The `ARCHIVE` Storage Engine

The `ARCHIVE` storage engine was added in MySQL 4.1.3. It is used for storing large amounts of data without indexes in a very small footprint.

To enable this storage engine, use the `--with-archive-storage-engine` option to **configure** when you build MySQL.

When you create an `ARCHIVE` table, the server creates a table definition file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data and metadata files have extensions of `.ARZ` and `.ARM`. An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports only `INSERT` and `SELECT`. (No deletes, replaces, or updates.) A `SELECT` performs a complete table scan. Records are compressed as they are inserted. Use of `OPTIMIZE TABLE` can analyze the table and pack it into a smaller format.

The `ARCHIVE` engine uses row-level locking.

14.8. The `CSV` Storage Engine

The `CSV` storage engine was added in MySQL 4.1.4. This engine stores data in text files using comma-separated-values format.

To enable this storage engine, use the `--with-csv-storage-engine` option to **configure** when you build MySQL.

When you create a `CSV` table, the server creates a table definition file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in `CSV` format.

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
+-----+-----+
| i     | c           |
+-----+-----+
|     1 | record one  |
|     2 | record two  |
+-----+-----+
2 rows in set (0.00 sec)
```

If you examine the `test.CSV` file in the database directory after executing the preceding statements, its contents look like this:

```
"1","record one"
```

"2", "record two"

The CSV storage engine does not support indexing.

14.9. The ISAM Storage Engine

The original storage engine in MySQL was the ISAM engine. It was the only storage engine available until MySQL 3.23, when the improved MyISAM engine was introduced as the default. ISAM is deprecated. As of MySQL 4.1, it's included in the source but not enabled in binary distributions. It is not available in MySQL 5.0. Embedded MySQL server versions do not support ISAM tables by default.

Due to the deprecated status of ISAM, and because MyISAM is an improvement over ISAM, you are advised to convert any remaining ISAM tables to MyISAM as soon as possible. To convert an ISAM table to a MyISAM table, use an ALTER TABLE statement:

```
mysql> ALTER TABLE tbl_name TYPE = MYISAM;
```

For more information about MyISAM, see Section 14.1, “The MyISAM Storage Engine”.

Each ISAM table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An .frm file stores the table definition. The data file has an .ISD extension. The index file has an .ISM extension.

ISAM uses B-tree indexes.

You can check or repair ISAM tables with the **isamchk** utility. See Section 5.8.3.7, “Using **myisamchk** for Crash Recovery”.

ISAM has the following properties:

- Compressed and fixed-length keys
- Fixed and dynamic record length
- 16 indexes per table, with 16 key parts per key
- Maximum key length 256 bytes (default)
- Data values are stored in machine format; this is fast, but machine/OS dependent

Many of the properties of MyISAM tables are also true for ISAM tables. However, there are also many differences. The following list describes some of the ways that ISAM is distinct from MyISAM:

- Not binary portable across OS/platforms.
- Can't handle tables larger than 4GB.
- Only supports prefix compression on strings.
- Smaller (more restrictive) key limits.
- Dynamic tables become more fragmented.
- Doesn't support MERGE tables.
- Tables are checked and repaired with **isamchk** rather than with **myisamchk**.

- Tables are compressed with **pack_isam** rather than with **myisampack**.
- Cannot be used with the `BACKUP TABLE` or `RESTORE TABLE` backup-related statements.
- Cannot be used with the `CHECK TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, or `ANALYZE TABLE` table-maintenance statements.
- No support for full-text searching or spatial data types.
- No support for multiple character sets per table.
- Indexes cannot be assigned to specific key caches.

Chapter 15. The InnoDB Storage Engine

15.1. InnoDB Overview

InnoDB provides MySQL with a transaction-safe (ACID compliant) storage engine with commit, rollback, and crash recovery capabilities. InnoDB does locking on the row level and also provides an Oracle-style consistent non-locking read in `SELECT` statements. These features increase multi-user concurrency and performance. There is no need for lock escalation in InnoDB because row-level locks in InnoDB fit in very little space. InnoDB also supports `FOREIGN KEY` constraints. In SQL queries you can freely mix InnoDB type tables with other table types of MySQL, even within the same query.

InnoDB has been designed for maximum performance when processing large data volumes. Its CPU efficiency is probably not matched by any other disk-based relational database engine.

Fully integrated with MySQL Server, the InnoDB storage engine maintains its own buffer pool for caching data and indexes in main memory. InnoDB stores its tables and indexes in a tablespace, which may consist of several files (or raw disk partitions). This is different from, for example, MyISAM tables where each table is stored using separate files. InnoDB tables can be of any size even on operating systems where file size is limited to 2GB.

InnoDB is included in binary distributions by default as of MySQL 4.0. For information about InnoDB support in MySQL 3.23, see Section 15.3, “InnoDB in MySQL 3.23”. Starting from MySQL 4.1.5, the new Windows installer makes InnoDB the MySQL default table type on Windows.

InnoDB is used in production at numerous large database sites requiring high performance. The famous Internet news site Slashdot.org runs on InnoDB. Myrix, Inc. stores over 1TB of data in InnoDB, and another site handles an average load of 800 inserts/updates per second in InnoDB.

InnoDB is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see <http://www.mysql.com/company/legal/licensing/>.

15.2. InnoDB Contact Information

Contact information for Innobase Oy, producer of the InnoDB engine:

Aleksanterinkatu 17
P.O.Box 800
00101 Helsinki
Finland

15.3. InnoDB in MySQL 3.23

Beginning with MySQL 4.0, InnoDB is enabled by default, so the following information applies only to MySQL 3.23.

InnoDB tables are included in the MySQL source distribution starting from 3.23.34a and are activated in the MySQL-Max binaries of the 3.23 series. For Windows, the MySQL-Max binaries are included in the standard distribution.

If you have downloaded a binary version of MySQL that includes support for InnoDB, simply follow the instructions of the MySQL manual for installing a binary version of MySQL. If you have MySQL 3.23 installed, the simplest way to install MySQL-Max is to replace the executable `mysqld` server with the corresponding executable from the MySQL-Max distribution. MySQL and MySQL-Max differ only in the server executable. See Section 2.7, “Installing MySQL on Other Unix-Like Systems” and Section 5.1.2, “The `mysqld-max` Extended MySQL Server”.

To compile the MySQL source code with InnoDB support, download MySQL 3.23.34a or newer from <http://www.mysql.com/> and configure MySQL with the `--with-innodb` option. See Section 2.8, “MySQL Installation Using a Source Distribution”.

To use InnoDB tables with MySQL 3.23, you must specify configuration parameters in the `[mysqld]` section of the `my.cnf` option file. On Windows, you can use `my.ini` instead. If you do not configure InnoDB in the option file, InnoDB does not start. (From MySQL 4.0 on, InnoDB uses default parameters if you do not specify any. However, to get best performance, it is still recommended that you use parameters appropriate for your system, as discussed in Section 15.4, “InnoDB Configuration”.)

In MySQL 3.23, you must specify at the minimum an `innodb_data_file_path` value to configure the InnoDB data files. For example, to configure InnoDB to use a single 500MB data file, place the following setting in the `[mysqld]` section of your option file:

```
[mysqld]
innodb_data_file_path=ibdata1:500M
```

InnoDB creates the `ibdata1` file in the MySQL data directory by default. To specify the location explicitly, specify an `innodb_data_home_dir` setting. See Section 15.4, “InnoDB Configuration”.

15.4. InnoDB Configuration

To enable InnoDB tables in MySQL 3.23, see Section 15.3, “InnoDB in MySQL 3.23”.

From MySQL 4.0 on, the InnoDB storage engine is enabled by default. If you don't want to use InnoDB tables, you can add the `skip-innodb` option to your MySQL option file.

Two important disk-based resources managed by the InnoDB storage engine are its tablespace data files and its log files.

If you specify no InnoDB configuration options, MySQL 4.0 and above creates an auto-extending 10MB data file named `ibdata1` and two 5MB log files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. (In MySQL 4.0.0 and 4.0.1, the data file is 64MB and not auto-extending.) In MySQL 3.23, InnoDB does not start if you provide no configuration options.

Note: InnoDB provides MySQL with a transaction-safe (ACID compliant) storage engine with commit, rollback, and crash recovery capabilities. **It cannot do so** if the underlying operating system and hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations in order to improve performance. On some operating systems, the very system call (`fsync()`) that should wait until all unwritten data for a file has been flushed may actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, you should perform some “pull-the-plug” tests before using anything in production. On Mac OS X 10.3 and later, InnoDB uses a special `fcntl()` file flush method. Under Linux, it is advisable to **disable the write-back cache**.

On ATAPI hard disks, a command like `hdparm -W0 /dev/hda` may work. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

Note: To get good performance, you should explicitly provide InnoDB parameters as discussed in

the following examples. Naturally, you should edit the settings to suit your hardware and requirements.

To set up the InnoDB tablespace files, use the `innodb_data_file_path` option in the `[mysqld]` section of the `my.cnf` option file. On Windows, you can use `my.ini` instead. The value of `innodb_data_file_path` should be a list of one or more data file specifications. If you name more than one data file, separate them by semicolon (`;`) characters:

```
innodb_data_file_path=logfile_spec1[;logfile_spec2]...
```

For example, a setting that explicitly creates a tablespace having the same characteristics as the MySQL 4.0 default is as follows:

```
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend
```

This setting configures a single 10MB data file named `ibdata1` that is auto-extending. No location for the file is given, so the default is the MySQL data directory.

Sizes are specified using `M` or `G` suffix letters to indicate units of MB or GB.

A tablespace containing a fixed-size 50MB data file named `ibdata1` and a 50MB auto-extending file named `ibdata2` in the data directory can be configured like this:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The full syntax for a data file specification includes the filename, its size, and several optional attributes:

```
file_name:file_size[ :autoextend[ :max:max_file_size ] ]
```

The `autoextend` attribute and those following can be used only for the last data file in the `innodb_data_file_path` line. `autoextend` is available starting from MySQL 3.23.50 and 4.0.2.

If you specify the `autoextend` option for the last data file, InnoDB extends the data file if it runs out of free space in the tablespace. The increment is 8MB at a time.

If the disk becomes full, you might want to add another data file on another disk. Instructions for reconfiguring an existing tablespace are given in Section 15.8, “Adding and Removing InnoDB Data and Log Files”.

InnoDB is not aware of the maximum file size, so be cautious on filesystems where the maximum file size is 2GB. To specify a maximum size for an auto-extending data file, use the `max` attribute. The following configuration allows `ibdata1` to grow up to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend:max:500M
```

InnoDB creates tablespace files in the MySQL data directory by default. To specify a location explicitly, use the `innodb_data_home_dir` option. For example, to use two files named `ibdata1` and `ibdata2` but create them in the `/ibdata` directory, configure InnoDB like this:

```
[mysqld]
innodb_data_home_dir = /ibdata
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

Note: InnoDB does not create directories, so make sure that the `/ibdata` directory exists before you start the server. This is also true of any log file directories that you configure. Use the Unix or

DOS `mkdir` command to create any necessary directories.

InnoDB forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name, adding a slash or backslash between if needed. If the `innodb_data_home_dir` option is not mentioned in `my.cnf` at all, the default value is the `dot` directory `./`, which means the MySQL data directory.

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for the data files listed in the `innodb_data_file_path` value. The following example is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
innodb_data_file_path=ibdata/ibdata1:50M;/ibdata/ibdata2:50M:autoextend
```

A simple `my.cnf` example. Suppose that you have a computer with 128MB RAM and one hard disk. The following example shows possible configuration parameters in `my.cnf` or `my.ini` for InnoDB. The example assumes the use of MySQL-Max 3.23.50 or later or MySQL 4.0.2 or later because it uses the `autoextend` attribute.

This example suits most users, both on Unix and Windows, who do not want to distribute InnoDB data files and log files on several disks. It creates an auto-extending data file `ibdata1` and two InnoDB log files `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Also, the small archived InnoDB log file `ib_arch_log_0000000000` that InnoDB creates automatically ends up in the data directory.

```
[mysqld]
# You can write your other MySQL server options here
# ...
# Data files must be able to hold your data and indexes.
# Make sure that you have enough free disk space.
innodb_data_file_path = ibdata1:10M:autoextend
#
# Set buffer pool size to 50-80% of your computer's memory
set-variable = innodb_buffer_pool_size=70M
set-variable = innodb_additional_mem_pool_size=10M
#
# Set the log file size to about 25% of the buffer pool size
set-variable = innodb_log_file_size=20M
set-variable = innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
```

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files or log files.

Note that data files must be less than 2GB in some filesystems. The combined size of the log files must be less than 4GB. The combined size of data files must be at least 10MB.

When you create an InnoDB tablespace for the first time, it is best that you start the MySQL server from the command prompt. InnoDB then prints the information about the database creation to the screen, so you can see what is happening. For example, on Windows, if `mysqld-max` is located in `C:\mysql\bin`, you can start it like this:

```
C:\> C:\mysql\bin\mysqld-max --console
```

If you do not send server output to the screen, check the server's error log to see what InnoDB prints during the startup process.

See Section 15.6, "Creating the InnoDB Tablespace" for an example of what the information displayed by InnoDB should look like.

Where to specify options on Windows? The rules for option files on Windows are as follows:

- Only one of `my.cnf` or `my.ini` should be created.
- The `my.cnf` file should be placed in the root directory of the C: drive.
- The `my.ini` file should be placed in the `WINDIR` directory; for example, `C:\WINDOWS` or `C:\WINNT`. You can use the `SET` command at the command prompt in a console window to print the value of `WINDIR`:

```
C:\> SET WINDIR
windir=C:\WINNT
```

- If your PC uses a boot loader where the C: drive is not the boot drive, your only option is to use the `my.ini` file.
- If you installed MySQL 4.1.5 or higher using the installation and configuration wizards, the `my.ini` file is located in your MySQL installation directory. See Section 2.3.5.14, “The Location of the `my.ini` File”.

Where to specify options on Unix? On Unix, `mysqld` reads options from the following files, if they exist, in the following order:

- `/etc/my.cnf`
Global options.
- `$MYSQL_HOME/my.cnf`
Server-specific options.
- `defaults-extra-file`
The file specified with the `--defaults-extra-file` option.
- `~/my.cnf`
User-specific options.

`MYSQL_HOME` represents an environment variable, which contains a path to the directory containing the server-specific `my.cnf` file.

If you want to make sure that `mysqld` reads options only from a specific file, you can use the `--defaults-file` option as the first option on the command line when starting the server:

```
mysqld --defaults-file=your_path_to_my_cnf
```

An advanced `my.cnf` example. Suppose that you have a Linux computer with 2GB RAM and three 60GB hard disks (at directory paths `/`, `/dr2` and `/dr3`). The following example shows possible configuration parameters in `my.cnf` for InnoDB.

```
[mysqld]
# You can write your other MySQL server options here
# ...
innodb_data_home_dir =
#
# Data files must be able to hold your data and indexes
innodb_data_file_path = /ibdata/ibdata1:2000M:/dr2/ibdata/ibdata2:2000M:autoext
#
```

```
# Set buffer pool size to 50-80% of your computer's memory,
# but make sure on Linux x86 total memory usage is < 2GB
set-variable = innodb_buffer_pool_size=1G
set-variable = innodb_additional_mem_pool_size=20M
innodb_log_group_home_dir = /dr3/iblogs
#
# innodb_log_arch_dir must be the same as innodb_log_group_home_dir
# (starting from 4.0.6, you can omit it)
innodb_log_arch_dir = /dr3/iblogs
set-variable = innodb_log_files_in_group=2
#
# Set the log file size to about 25% of the buffer pool size
set-variable = innodb_log_file_size=250M
set-variable = innodb_log_buffer_size=8M
#
innodb_flush_log_at_trx_commit=1
set-variable = innodb_lock_wait_timeout=50
#
# Uncomment the next lines if you want to use them
#innodb_flush_method=fdatasync
#set-variable = innodb_thread_concurrency=5
```

Note that the example places the two data files on different disks. InnoDB fills the tablespace beginning with the first data file. In some cases, it improves the performance of the database if all data is not placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. You can also use raw disk partitions (raw devices) as InnoDB data files, which may speed up I/O. See Section 15.15.2, “Using Raw Devices for the Tablespace”.

Warning: On 32-bit GNU/Linux x86, you must be careful not to set memory usage too high. glibc may allow the process heap to grow over thread stacks, which crashes your server. It is a risk if the value of the following expression is close to or exceeds 2GB:

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL AB binaries) and in the worst case also uses `sort_buffer_size + read_buffer_size` additional memory.

Starting from MySQL 4.1, by compiling MySQL yourself, you can use up to 64GB of physical memory in 32-bit Windows. See the description for `innodb_buffer_pool_aware_mem_mb` in Section 15.5, “InnoDB Startup Options”.

How to tune other mysqld server parameters? The following values are typical and suit most users:

```
[mysqld]
skip-external-locking
set-variable = max_connections=200
set-variable = read_buffer_size=1M
set-variable = sort_buffer_size=1M
#
# Set key_buffer to 5 - 50% of your RAM depending on how much
# you use MyISAM tables, but keep key_buffer_size + InnoDB
# buffer pool size < 80% of your RAM
set-variable = key_buffer_size=...
```

15.5. InnoDB Startup Options

This section describes the InnoDB-related server options. In MySQL 4.0 and up, all of them can be specified in `--opt_name=value` form on the command line or in option files. Before MySQL 4.0, numeric options should be specified using `--set-variable=opt_name=value` or `-O`

opt_name=value syntax.

- `innodb_additional_mem_pool_size`

The size of a memory pool InnoDB uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you need to allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system, and writes warning messages to the MySQL error log. The default value is 1MB.

- `innodb_autoextend_increment`

The increment size (in megabytes) for extending the size of an autoextending tablespace when it becomes full. The default value is 8. This option is available starting from MySQL 4.0.24 and 4.1.5. As of MySQL 4.0.24 and 4.1.6, it can be changed at runtime as a global system variable.

- `innodb_buffer_pool_ave_mem_mb`

The size of the buffer pool (in MB), if it is placed in the AWE memory of 32-bit Windows. Available from MySQL 4.1.0 and relevant only in 32-bit Windows. If your 32-bit Windows operating system supports more than 4GB memory, so-called "Address Windowing Extensions," you can allocate the InnoDB buffer pool into the AWE physical memory using this parameter. The maximum possible value for this is 64000. If this parameter is specified, `innodb_buffer_pool_size` is the window in the 32-bit address space of `mysqld` where InnoDB maps that AWE memory. A good value for `innodb_buffer_pool_size` is 500MB.

- `innodb_buffer_pool_size`

The size of the memory buffer InnoDB uses to cache data and indexes of its tables. The larger you set this value, the less disk I/O is needed to access data in tables. On a dedicated database server, you may set this to up to 80% of the machine physical memory size. However, do not set it too large because competition for the physical memory might cause paging in the operating system.

- `innodb_checksums`

InnoDB uses checksum validation on all pages read from the disk to ensure extra fault tolerance against broken hardware or data files. However, under some rare circumstances (such as when running benchmarks) this "extra safety" feature is unneeded. In such cases, this option (which is enabled by default) can be turned off with `--skip-innodb-checksums`. This option was added in MySQL 5.0.3.

- `innodb_data_file_path`

The paths to individual data files and their sizes. The full directory path to each data file is acquired by concatenating `innodb_data_home_dir` to each path specified here. The file sizes are specified in megabytes or gigabytes (1024MB) by appending M or G to the size value. The sum of the sizes of the files must be at least 10MB. On some operating systems, files must be less than 2GB. If you do not specify `innodb_data_file_path`, the default behavior starting from 4.0 is to create a single 10MB auto-extending data file named `ibdata1`. Starting from 3.23.44, you can set the file size bigger than 4GB on those operating systems that support big files. You can also use raw disk partitions as data files. See Section 15.15.2, "Using Raw Devices for the Tablespace".

- `innodb_data_home_dir`

The common part of the directory path for all InnoDB data files. If you do not set this value, the default is the MySQL data directory. You can specify this also as an empty string, in which case you can use absolute file paths in `innodb_data_file_path`.

- `innodb_doublewrite`

By default, InnoDB stores all data twice, first to the doublewrite buffer, and then to the actual data files. This option can be used to disable this functionality. Like `innodb_checksums`, this option is enabled by default; it can be turned off with `--skip-innodb-doublewrite` for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures. This option was added in MySQL 5.0.3.

- `innodb_fast_shutdown`

If you set this to 0, InnoDB does a full purge and an insert buffer merge before a shutdown. These operations can take minutes, or even hours in extreme cases. If you set this parameter to 1, InnoDB skips these operations at shutdown. The default value is 1 starting from 3.23.50. If you set it to 2 (available starting from MySQL 5.0.5, except on Netware) InnoDB will just flush its logs and then shut down brutally (and fastly) like if it was a MySQL crash; no committed transaction will be lost, but a crash recovery will be done at next startup.

- `innodb_file_io_threads`

The number of file I/O threads in InnoDB. Normally this should be left at the default value of 4, but disk I/O on Windows may benefit from a larger number. On Unix, increasing the number has no effect; InnoDB always uses the default value. This option is available as of MySQL 3.23.37.

- `innodb_file_per_table`

NOTE: A bug in versions $\leq 4.1.8$ if you specify `innodb_file_per_table` in `my.cnf`! If you shut down **mysqld**, then records may disappear from the secondary indexes of a table. See (Bug #7496 [<http://bugs.mysql.com/7496>]) for more information and workarounds. This is fixed in 4.1.9, but another bug (Bug #8021 [<http://bugs.mysql.com/8021>]) bit the Windows version in 4.1.9, and in the Windows version of 4.1.9 you must put the line `innodb_flush_method=unbuffered` to your `my.cnf` or `my.ini` to get **mysqld** to work.

This option causes InnoDB to create each new table using its own `.ibd` file for storing data and indexes, rather than in the shared tablespace. See Section 15.7.6, “Using Per-Table Tablespaces”. This option is available as of MySQL 4.1.1.

- `innodb_flush_log_at_trx_commit`

When `innodb_flush_log_at_trx_commit` is set to 0, once per second the log buffer is written out to the log file, and the flush to disk operation is performed on the log file, but nothing is done at a transaction commit. When this value is 1 (the default), at each transaction commit the log buffer is written out to the log file, and the flush to disk operation is performed on the log file. When set to 2, at each commit the log buffer is written out to the file, but the flush to disk operation is not performed on it. However, the flushing on the log file takes place once per second also in the case of 2. We must note that the once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues. You can achieve better performance by setting the value different from 1, but then you can lose at most one second worth of transactions in a crash. If you set the value to 0, then any **mysqld** process crash can erase the last second of transactions. If you set the value to 2, then only an operating system crash or a power outage can erase the last second of transactions. Note that many operating systems and some disk hardware fool in the flush-to-disk operation. They may tell to **mysqld** that the flush has taken place, though it has not. Then the durability of transactions is not guaranteed even with the setting 1, and in the worst case a power outage can even corrupt the InnoDB database. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try using the Unix command **hdparm** to disable the caching of disk writes in hardware caches, or use some other command specific to the hardware vendor. The default value of this option is 1 (prior to MySQL 4.0.13, the default is 0).

- `innodb_flush_method`

This option is relevant only on Unix systems. If set to `fdatasync`, InnoDB uses `fsync()` to flush both the data and log files. If set to `O_DSYNC`, InnoDB uses `O_SYNC` to open and flush the log files, but uses `fsync()` to flush the data files. If `O_DIRECT` is specified (available on

some GNU/Linux versions starting from MySQL 4.0.14), InnoDB uses `O_DIRECT` to open the data files, and uses `fsync()` to flush both the data and log files. Note that InnoDB does not use `fdatasync` or `O_DSYNC` by default because there have been problems with them on many Unix flavors. This option is available as of MySQL 3.23.40.

- `innodb_force_recovery`

Warning: This option should be defined only in an emergency situation when you want to dump your tables from a corrupt database! Possible values are from 1 to 6. The meanings of these values are described in Section 15.9.1, “Forcing Recovery”. As a safety measure, InnoDB prevents a user from modifying data when this option is greater than 0. This option is available starting from MySQL 3.23.44.

- `innodb_lock_wait_timeout`

The timeout in seconds an InnoDB transaction may wait for a lock before being rolled back. InnoDB automatically detects transaction deadlocks in its own lock table and rolls back the transaction. Beginning with MySQL 4.0.20 and 4.1.2, InnoDB notices locks set using the `LOCK TABLES` statement. Before that, if you use the `LOCK TABLES` statement, or other transaction-safe storage engines than InnoDB in the same transaction, a deadlock may arise that InnoDB cannot notice. In cases like this, the timeout is useful to resolve the situation. The default is 50 seconds.

- `innodb_locks_unsafe_for_binlog`

This option turns off next-key locking in InnoDB searches and index scans. Default value for this option is false.

Normally InnoDB uses an algorithm called “next-key locking.” InnoDB does the row-level locking in such a way that when it searches or scans an index of a table, it sets shared or exclusive locks on the index records it encounters. Thus the row-level locks are actually index record locks. The locks InnoDB sets on index records also affect the “gap” before that index record. If a user has a shared or exclusive lock on record R in an index, another user cannot insert a new index record immediately before R in the index order. This option causes InnoDB not to use next-key locking in searches or index scans. Next-key locking is still used to ensure foreign key constraints and duplicate key checking. Note that using this option may cause phantom problems: Suppose that you want to read and lock all children from the `child` table with an identifier value larger than 100, with the intent of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

Suppose that there is an index on the `id` column. The query scans that index starting from the first record where `id` is bigger than 100. If the locks set on the index records do not lock out inserts made in the gaps, a new row is meanwhile inserted to the table. If you execute the same `SELECT` within the same transaction, you see a new row in the result set returned by the query. This also means, that if new items are added to the database, InnoDB does not guarantee serializability instead conflict serializability is still guaranteed. Therefore, if this option is used InnoDB guarantees at most isolation level `READ COMMITTED`. This option is available as of MySQL 4.1.4.

Starting from MySQL 5.0.2 this option is even more unsafe. InnoDB in an `UPDATE` or a `DELETE` only locks rows that it updates or deletes. This greatly reduces the probability of deadlocks but they can happen. Note that this option still does not allow e.g. `UPDATE` to overtake other `UPDATE` even the case when both updates different rows. Consider following example:

```
CREATE TABLE A(A INT NOT NULL, B INT);
INSERT INTO A VALUES (1,2), (2,3), (3,2), (4,3), (5,2);
COMMIT;
```

If one connection executes a query:

```
SET AUTOCOMMIT = 0;  
UPDATE A SET B = 5 WHERE B = 3;
```

and the other connection executes after the first one a query:

```
SET AUTOCOMMIT = 0;  
UPDATE A SET B = 4 WHERE B = 2;
```

Then query two has to wait for a commit or rollback of query one, because query one has an exclusive lock to a row (2,3), and query two while scanning rows also tries to take an exclusive lock to the row (2,3) which it cannot have. This is because query two first takes an exclusive lock to a row and then checks does this row belong to the result set and if not then releases the unnecessary lock when option `innodb_locks_unsafe_for_binlog` is used.

Therefore, query one is executed as follows:

```
x-lock(1,2)  
unlock(1,2)  
x-lock(2,3)  
update(2,3) to (2,5)  
x-lock(3,2)  
unlock(3,2)  
x-lock(4,3)  
update(4,3) to (4,5)  
x-lock(5,2)  
unlock(5,2)
```

and then query two is executed as follows:

```
x-lock(1,2)  
update(1,2) to (1,4)  
x-lock(2,3) - wait for query one to commit or rollback
```

- `innodb_log_arch_dir`

The directory where fully written log files would be archived if we used log archiving. The value of this parameter should currently be set the same as `innodb_log_group_home_dir`. Starting from MySQL 4.0.6, you may omit this option.

- `innodb_log_archive`

This value should currently be set to 0. Because recovery from a backup is done by MySQL using its own log files, there is currently no need to archive InnoDB log files. The default for this option is 0.

- `innodb_log_buffer_size`

The size of the buffer that InnoDB uses to write to the log files on disk. Sensible values range from 1MB to 8MB. The default is 1MB. A large log buffer allows large transactions to run without a need to write the log to disk before the transactions commit. Thus, if you have big transactions, making the log buffer larger saves disk I/O.

- `innodb_log_file_size`

The size of each log file in a log group. The combined size of log files must be less than 4GB on 32-bit computers. The default is 5MB. Sensible values range from 1MB to 1/N-th of the size of the buffer pool, below, where *N* is the number of log files in the group. The larger the value, the

less checkpoint flush activity is needed in the buffer pool, saving disk I/O. But larger log files also mean that recovery is slower in case of a crash.

- `innodb_log_files_in_group`

The number of log files in the log group. InnoDB writes to the files in a circular fashion. The default is 2 (recommended).

- `innodb_log_group_home_dir`

The directory path to the InnoDB log files. It must have the same value as `innodb_log_arch_dir`. If you do not specify any InnoDB log parameters, the default is to create two 5MB files names `ib_logfile0` and `ib_logfile1` in the MySQL data directory.

- `innodb_max_dirty_pages_pct`

This is an integer in the range from 0 to 100. The default is 90. The main thread in InnoDB tries to flush pages from the buffer pool so that at most this many percent of pages may not yet flushed been flushed at any particular time. Available starting from 4.0.13 and 4.1.1. If you have the SUPER privilege, this percentage can be changed while the server is running:

```
SET GLOBAL innodb_max_dirty_pages_pct = value;
```

- `innodb_max_purge_lag`

This option controls how to delay INSERT, UPDATE and DELETE operations when the purge operations (see Section 15.13, “Implementation of Multi-Versioning”) are lagging. The default value of this parameter is zero, meaning that there are no delays. This option can be changed at runtime as a global system variable. `innodb_max_purge_lag` is available as of MySQL 4.0.22 and 4.1.6.

The InnoDB transaction system maintains a list of transactions that have delete-marked index records by UPDATE or DELETE operations. Let the length of this list be *purge_lag*. When *purge_lag* exceeds `innodb_max_purge_lag`, each INSERT, UPDATE and DELETE operation is delayed by $((\text{purge_lag}/\text{innodb_max_purge_lag}) * 10) - 5$ milliseconds. The delay is computed in the beginning of a purge batch, every ten seconds. The operations are not delayed if purge cannot run because of an old consistent read view that could see the rows to be purged.

A typical setting for a problematic workload might be 1 million, assuming that our transactions are small, only 100 bytes in size, and we can allow 100 MB of unpurged rows in our tables.

- `innodb_mirrored_log_groups`

The number of identical copies of log groups we keep for the database. Currently this should be set to 1.

- `innodb_open_files`

This option is relevant only if you use multiple tablespaces in InnoDB. It specifies the maximum number of `.ibd` files that InnoDB can keep open at one time. The minimum value is 10. The default is 300. This option is available as of MySQL 4.1.1.

The file descriptors used for `.ibd` files are for InnoDB only. They are independent of those specified by the `--open-files-limit` server option, and do not affect the operation of the table cache.

- `innodb_table_locks`

Starting from MySQL 4.0.20, and 4.1.2, InnoDB honors `LOCK TABLES`; MySQL does not return from `LOCK TABLE ... WRITE` until all other threads have released all their locks to the

table. In MySQL 4.0.19 and before, InnoDB ignored table locks, which allowed one to more easily simulate transactions with a combination of MyISAM and InnoDB tables. The default value is 1, which means that `LOCK TABLES` causes also InnoDB internally to take a table lock. In applications using `AUTOCOMMIT=1`, InnoDB's internal table locks can cause deadlocks. You can set `innodb_table_locks=0` in `my.cnf` to remove that problem.

- `innodb_thread_concurrency`

InnoDB tries to keep the number of operating system threads concurrently inside InnoDB less than or equal to the limit given by this parameter. The default value is 8. If you have low performance and `SHOW INNODB STATUS` reveals many threads waiting for semaphores, you may have thread thrashing and should try setting this parameter lower or higher. If you have a computer with many processors and disks, you can try setting the value higher to better utilize the resources of your computer. A recommended value is the sum of the number of processors and disks your system has. A value of 500 or greater disables the concurrency checking. This option is available starting from MySQL 3.23.44 and 4.0.1.

- `innodb_status_file`

This option causes InnoDB to create a file `<datadir>/innodb_status.<pid>` for periodic `SHOW INNODB STATUS` output. This option is available as of MySQL 4.0.21.

15.6. Creating the InnoDB Tablespace

Suppose that you have installed MySQL and have edited your option file so that it contains the necessary InnoDB configuration parameters. Before starting MySQL, you should verify that the directories you have specified for InnoDB data files and log files exist and that the MySQL server has access rights to those directories. InnoDB cannot create directories, only files. Check also that you have enough disk space for the data and log files.

It is best to run the MySQL server `mysqld` from the command prompt when you create an InnoDB database, not from the `mysqld_safe` wrapper or as a Windows service. When you run from a command prompt you see what `mysqld` prints and what is happening. On Unix, just invoke `mysqld`. On Windows, use the `--console` option.

When you start the MySQL server after initially configuring InnoDB in your option file, InnoDB creates your data files and log files. InnoDB prints something like the following:

```
InnoDB: The first specified datafile /home/heikki/data/ibdata1
did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file /home/heikki/data/ibdata1 size to 134217728
InnoDB: Database physically writes the file full: wait...
InnoDB: datafile /home/heikki/data/ibdata2 did not exist:
new to be created
InnoDB: Setting file /home/heikki/data/ibdata2 size to 262144000
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file /home/heikki/data/logs/ib_logfile0 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile0 size
to 5242880
InnoDB: Log file /home/heikki/data/logs/ib_logfile1 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile1 size
to 5242880
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: Creating foreign key constraint system tables
InnoDB: Foreign key constraint system tables created
InnoDB: Started
mysqld: ready for connections
```

A new InnoDB database has been created. You can connect to the MySQL server with the usual MySQL client programs like `mysql`. When you shut down the MySQL server with `mysqladmin shutdown`, the output is like the following:

```
010321 18:33:34 mysqld: Normal shutdown
010321 18:33:34 mysqld: Shutdown Complete
InnoDB: Starting shutdown...
InnoDB: Shutdown completed
```

You can look at the data file and log directories and you see the files created. The log directory also contains a small file named `ib_arch_log_0000000000`. That file resulted from the database creation, after which InnoDB switched off log archiving. When MySQL is started again, the data files and log files have been created, so the output is much briefer:

```
InnoDB: Started
mysqld: ready for connections
```

Starting from MySQL 4.1.1, you can add the option `innodb_file_per_table` to `my.cnf`, and make InnoDB to store each table into its own `.ibd` file in a database directory of MySQL. See Section 15.7.6, “Using Per-Table Tablespaces”.

15.6.1. Dealing with InnoDB Initialization Problems

If InnoDB prints an operating system error in a file operation, usually the problem is one of the following:

- You did not create the InnoDB data file directory or the InnoDB log directory.
- `mysqld` does not have access rights to create files in those directories.
- `mysqld` cannot not read the proper `my.cnf` or `my.ini` option file, and consequently does not see the options you specified.
- The disk is full or a disk quota is exceeded.
- You have created a subdirectory whose name is equal to a data file you specified.
- There is a syntax error in `innodb_data_home_dir` or `innodb_data_file_path`.

If something goes wrong when InnoDB attempts to initialize its tablespace or its log files, you should delete all files created by InnoDB. This means all `ibdata` files and all `ib_logfiles`. In case you created some InnoDB tables, delete the corresponding `.frm` files for these tables (and any `.ibd` files if you are using multiple tablespaces) from the MySQL database directories as well. Then you can try the InnoDB database creation again. It is best to start the MySQL server from a command prompt so that you see what is happening.

15.7. Creating InnoDB Tables

Suppose that you have started the MySQL client with the command `mysql test`. To create an InnoDB table, you must specify an `ENGINE = InnoDB` or `TYPE = InnoDB` option in the table creation SQL statement:

```
CREATE TABLE customers (a INT, b CHAR (20), INDEX (a)) ENGINE=InnoDB;
CREATE TABLE customers (a INT, b CHAR (20), INDEX (a)) TYPE=InnoDB;
```

The SQL statement creates a table and an index on column `a` in the InnoDB tablespace that consists of the data files you specified in `my.cnf`. In addition, MySQL creates a file `customers.frm` in the `test` directory under the MySQL database directory. Internally, InnoDB adds to

its own data dictionary an entry for table 'test/customers'. This means you can create a table of the same name `customers` in some other database, and the table names do not collide inside InnoDB.

You can query the amount of free space in the InnoDB tablespace by issuing a `SHOW TABLE STATUS` statement for any InnoDB table. The amount of free space in the tablespace appears in the Comment section in the output of `SHOW TABLE STATUS`. An example:

```
SHOW TABLE STATUS FROM test LIKE 'customers'
```

Note that the statistics `SHOW` gives about InnoDB tables are only approximate. They are used in SQL optimization. Table and index reserved sizes in bytes are accurate, though.

15.7.1. How to Use Transactions in InnoDB with Different APIs

By default, each client that connects to the MySQL server begins with autocommit mode enabled, which automatically commits every SQL statement you run. To use multiple-statement transactions, you can switch autocommit off with the SQL statement `SET AUTOCOMMIT = 0` and use `COMMIT` and `ROLLBACK` to commit or roll back your transaction. If you want to leave autocommit on, you can enclose your transactions between `START TRANSACTION` and `COMMIT` or `ROLLBACK`. Before MySQL 4.0.11, you have to use the keyword `BEGIN` instead of `START TRANSACTION`. The following example shows two transactions. The first is committed and the second is rolled back.

```
shell> mysql test
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 5 to server version: 3.23.50-log
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql> CREATE TABLE CUSTOMER (A INT, B CHAR (20), INDEX (A))
-> TYPE=InnoDB;
Query OK, 0 rows affected (0.00 sec)
mysql> BEGIN;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO CUSTOMER VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> SET AUTOCOMMIT=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO CUSTOMER VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM CUSTOMER;
+-----+-----+
| A     | B           |
+-----+-----+
|    10 | Heikki     |
+-----+-----+
1 row in set (0.00 sec)
mysql>
```

In APIs like PHP, Perl DBI/DBD, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

15.7.2. Converting MyISAM Tables to InnoDB

Important: You should not convert MySQL system tables in the `mysql` database (such as `user` or `host`) to the InnoDB type. The system tables must always be of the MyISAM type.

If you want all your (non-system) tables to be created as InnoDB tables, you can, starting from the

MySQL 3.23.43, add the line `default-table-type=innodb` to the `[mysqld]` section of your `my.cnf` or `my.ini` file.

InnoDB does not have a special optimization for separate index creation the way the MyISAM storage engine does. Therefore, it does not pay to export and import the table and create indexes afterward. The fastest way to alter a table to InnoDB is to do the inserts directly to an InnoDB table. That is, use `ALTER TABLE ... TYPE=INNODB`, or create an empty InnoDB table with identical definitions and insert the rows with `INSERT INTO ... SELECT * FROM ...`.

If you have UNIQUE constraints on secondary keys, starting from MySQL 3.23.52, you can speed up a table import by turning off the uniqueness checks temporarily during the import session: `SET UNIQUE_CHECKS=0`; For big tables, this saves a lot of disk I/O because InnoDB can then use its insert buffer to write secondary index records in a batch.

To get better control over the insertion process, it might be good to insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
  WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records have been inserted, you can rename the tables.

During the conversion of big tables, you should increase the size of the InnoDB buffer pool to reduce disk I/O. Do not use more than 80% of the physical memory, though. You can also increase the sizes of the InnoDB log files and the log files.

Make sure that you do not fill up the tablespace: InnoDB tables require a lot more disk space than MyISAM tables. If an `ALTER TABLE` runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, InnoDB uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. In rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see Section 15.9.1, “Forcing Recovery”.

15.7.3. How an AUTO_INCREMENT Column Works in InnoDB

If you specify an `AUTO_INCREMENT` column for a table, the InnoDB table handle in the data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. The auto-increment counter is stored only in main memory, not on disk.

InnoDB uses the following algorithm to initialize the auto-increment counter for a table `T` that contains an `AUTO_INCREMENT` column named `ai_col`: After a server startup, when a user first does an insert to a table `T`, InnoDB executes the equivalent of this statement:

```
SELECT MAX(ai_col) FROM T FOR UPDATE;
```

The value retrieved by the statement is incremented by one and assigned to the column and the auto-increment counter of the table. If the table is empty, the value 1 is assigned. If the auto-increment counter is not initialized and the user invokes a `SHOW TABLE STATUS` statement that displays output for the table `T`, the counter is initialized (but not incremented) and stored for use by later inserts. Note that in this initialization we do a normal exclusive-locking read on the table and the lock lasts to the end of the transaction.

InnoDB follows the same procedure for initializing the auto-increment counter for a freshly created table.

Note that if the user specifies `NULL` or `0` for the `AUTO_INCREMENT` column in an `INSERT`, InnoDB treats the row as if the value had not been specified and generates a new value for it.

After the auto-increment counter has been initialized, if a user inserts a row that explicitly specifies the column value, and the value is bigger than the current counter value, the counter is set to the specified column value. If the user does not explicitly specify a value, InnoDB increments the counter by one and assigns the new value to the column.

When accessing the auto-increment counter, InnoDB uses a special table level AUTO-INC lock that it keeps to the end of the current SQL statement, not to the end of the transaction. The special lock release strategy was introduced to improve concurrency for inserts into a table containing an AUTO_INCREMENT column. Two transactions cannot have the AUTO-INC lock on the same table simultaneously.

Note that you may see gaps in the sequence of values assigned to the AUTO_INCREMENT column if you roll back transactions that have gotten numbers from the counter.

The behavior of the auto-increment mechanism is not defined if a user assigns a negative value to the column or if the value becomes bigger than the maximum integer that can be stored in the specified integer type.

Beginning with MySQL 5.0.3, InnoDB supports the AUTO_INCREMENT = *n* table option in CREATE TABLE and ALTER TABLE statements, to set the initial counter value or alter the current counter value. The effect of this option is canceled by a server restart, for reasons discussed earlier in this section.

15.7.4. FOREIGN KEY Constraints

Starting from MySQL 3.23.44, InnoDB features foreign key constraints.

The syntax of a foreign key constraint definition in InnoDB looks like this:

```
[CONSTRAINT symbol] FOREIGN KEY [id] (index_col_name, ...)
  REFERENCES tbl_name (index_col_name, ...)
  [ON DELETE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
  [ON UPDATE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
```

Foreign keys definitions are subject to the following conditions:

- Both tables must be InnoDB type.
- In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order.
- In the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- Index prefixes on foreign key columns are not supported. One consequence of this is that BLOB and TEXT columns cannot be included in a foreign key, because indexes on those columns must always include a prefix length.

InnoDB rejects any INSERT or UPDATE operation that attempts to create a foreign key value in a child table without a matching candidate key value in the parent table. The action InnoDB takes for any UPDATE or DELETE operation that attempts to update or delete a candidate key value in the parent table that has some matching rows in the child table is dependent on the *referential action* specified using ON UPDATE and ON DELETE subclauses of the FOREIGN KEY clause. When the user attempts to delete or update a row from a parent table, and there are one or more matching rows in the child table, InnoDB supports five options regarding the action to be taken:

- CASCADE: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. ON DELETE CASCADE is available starting from MySQL 3.23.50 and ON UPDATE CASCADE is available starting from 4.0.8.

- `SET NULL`: Delete or update the row from the parent table and set the foreign key column(s) in the child table to `NULL`. This is only valid if the foreign key columns do not have the `NOT NULL` qualifier specified. `ON DELETE SET NULL` is available starting from MySQL 3.23.50 and `ON UPDATE SET NULL` is available starting from 4.0.8.
- `NO ACTION`: In ANSI SQL-92 standard, `NO ACTION` means *no action* in the sense that an attempt to delete or update a primary key value will not be allowed to proceed if there is a related foreign key value in the referenced table (Gruber, *Mastering SQL*, 2000:181). Starting from 4.0.18 InnoDB rejects the delete or update operation for the parent table.
- `RESTRICT`: Rejects the delete or update operation for the parent table. `NO ACTION` and `RESTRICT` are the same as omitting the `ON DELETE` or `ON UPDATE` clause. (Some database systems have deferred checks, and `NO ACTION` is a deferred check. In MySQL, foreign key constraints are checked immediately, so `NO ACTION` and `RESTRICT` are the same.)
- `SET DEFAULT`: This action is recognized by the parser, but InnoDB rejects table definitions containing `ON DELETE SET DEFAULT` or `ON UPDATE SET DEFAULT` clauses.

InnoDB supports the same options when the candidate key in the parent table is updated. With `CASCADE`, the foreign key column(s) in the child table are set to new value(s) of the candidate key in the parent table. In the same way, the updates cascade if updated column(s) in the child table reference foreign keys in another table.

Note that InnoDB supports foreign key references within a table and in these cases child table really means dependent records within the table.

InnoDB needs indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. Starting with MySQL 4.1.2, these indexes are created automatically. In older versions, the indexes must be created explicitly or the creation of foreign key constraints fails.

Corresponding columns in the foreign key and the referenced key must have similar internal data types inside InnoDB so that they can be compared without a type conversion. The **size and the signedness of integer types has to be the same**. The length of string types need not be the same. If you specify a `SET NULL` action, make sure that you have **not declared the columns in the child table** as `NOT NULL`.

If MySQL reports an error number 1005 from a `CREATE TABLE` statement, and the error message string refers to `errno 150`, this means that the table creation failed because a foreign key constraint was not correctly formed. Similarly, if an `ALTER TABLE` fails and it refers to `errno 150`, that means a foreign key definition would be incorrectly formed for the altered table. Starting from MySQL 4.0.13, you can use `SHOW INNODB STATUS` to display a detailed explanation of the latest InnoDB foreign key error in the server.

Starting from MySQL 3.23.50, InnoDB does not check foreign key constraints on those foreign key or referenced key values that contain a `NULL` column.

A deviation from SQL standards: If in the parent table there are several rows that have the same referenced key value, then InnoDB acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, InnoDB does not allow the deletion of any of those parent rows.

InnoDB performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.

A deviation from SQL standards: If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible from 4.0.13. A self-referential `ON DELETE CASCADE` has been possible since `ON DELETE` was implemented. Since 4.0.21, cascading operations may not be nested more than 15 levels.

A deviation from SQL standards: Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, InnoDB checks UNIQUE and FOREIGN KEY constraints row-by-row. According to the SQL standard, the default behavior should be that constraints are only checked after the WHOLE SQL statement has been processed.

A simple example that relates parent and child tables through a single-column foreign key:

```
CREATE TABLE parent(id INT NOT NULL,
                    PRIMARY KEY (id)
) TYPE=INNODB;
CREATE TABLE child(id INT, parent_id INT,
                   INDEX par_ind (parent_id),
                   FOREIGN KEY (parent_id) REFERENCES parent(id)
                   ON DELETE CASCADE
) TYPE=INNODB;
```

A more complex example in which a product_order table has foreign keys for two other tables. One foreign key references a two-column index in the product table. The other references a single-column index in the customer table:

```
CREATE TABLE product (category INT NOT NULL, id INT NOT NULL,
                      price DECIMAL,
                      PRIMARY KEY(category, id)) TYPE=INNODB;
CREATE TABLE customer (id INT NOT NULL,
                       PRIMARY KEY (id)) TYPE=INNODB;
CREATE TABLE product_order (no INT NOT NULL AUTO_INCREMENT,
                             product_category INT NOT NULL,
                             product_id INT NOT NULL,
                             customer_id INT NOT NULL,
                             PRIMARY KEY(no),
                             INDEX (product_category, product_id),
                             FOREIGN KEY (product_category, product_id)
                             REFERENCES product(category, id)
                             ON UPDATE CASCADE ON DELETE RESTRICT,
                             INDEX (customer_id),
                             FOREIGN KEY (customer_id)
                             REFERENCES customer(id)) TYPE=INNODB;
```

Starting from MySQL 3.23.50, InnoDB allows you to add a new foreign key constraint to a table by using ALTER TABLE:

```
ALTER TABLE yourtablename
  ADD [CONSTRAINT symbol] FOREIGN KEY [id] (index_col_name, ...)
  REFERENCES tbl_name (index_col_name, ...)
  [ON DELETE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
  [ON UPDATE {RESTRICT | CASCADE | SET NULL | NO ACTION}]
```

Remember to create the required indexes first. You can also add a self-referential foreign key constraint to a table using ALTER TABLE.

Starting from MySQL 4.0.13, InnoDB supports the use of ALTER TABLE to drop foreign keys:

```
ALTER TABLE yourtablename DROP FOREIGN KEY fk_symbol;
```

If the FOREIGN KEY clause included a CONSTRAINT name when you created the foreign key, you can refer to that name to drop the foreign key. (A constraint name can be given as of MySQL 4.0.18.) Otherwise, the *fk_symbol* value is internally generated by InnoDB when the foreign key is created. To find out the symbol when you want to drop a foreign key, use the SHOW CREATE TABLE statement. An example:

```
mysql> SHOW CREATE TABLE ibtest11c\G
***** 1. row *****
      Table: ibtest11c
```

```

Create Table: CREATE TABLE `ibtest11c` (
  `A` int(11) NOT NULL auto_increment,
  `D` int(11) NOT NULL default '0',
  `B` varchar(200) NOT NULL default '',
  `C` varchar(175) default NULL,
  PRIMARY KEY (`A`,`D`,`B`),
  KEY `B` (`B`,`C`),
  KEY `C` (`C`),
  CONSTRAINT `0_38775` FOREIGN KEY (`A`, `D`)
REFERENCES `ibtest11a` (`A`, `D`)
ON DELETE CASCADE ON UPDATE CASCADE,
  CONSTRAINT `0_38776` FOREIGN KEY (`B`, `C`)
REFERENCES `ibtest11a` (`B`, `C`)
ON DELETE CASCADE ON UPDATE CASCADE
) TYPE=InnoDB CHARSET=latin1
1 row in set (0.01 sec)

mysql> ALTER TABLE ibtest11c DROP FOREIGN KEY 0_38775;

```

Starting from MySQL 3.23.50, the InnoDB parser allows you to use backticks around table and column names in a FOREIGN KEY ... REFERENCES ... clause. Starting from MySQL 4.0.5, the InnoDB parser also takes into account the lower_case_table_names system variable setting.

Before MySQL 3.23.50, ALTER TABLE or CREATE INDEX should not be used in connection with tables that have foreign key constraints or that are referenced in foreign key constraints: Any ALTER TABLE removes all foreign key constraints defined for the table. You should not use ALTER TABLE with the referenced table, either. Instead, use DROP TABLE and CREATE TABLE to modify the schema. When MySQL does an ALTER TABLE it may internally use RENAME TABLE, and that confuses the foreign key constraints that refer to the table. In MySQL, a CREATE INDEX statement is processed as an ALTER TABLE, so the same considerations apply.

Starting from MySQL 3.23.50, InnoDB returns the foreign key definitions of a table as part of the output of the SHOW CREATE TABLE statement:

```
SHOW CREATE TABLE tbl_name;
```

From this version, **mysqldump** also produces correct definitions of tables to the dump file, and does not forget about the foreign keys.

You can display the foreign key constraints for a table like this:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name'
```

The foreign key constraints are listed in the Comment column of the output.

When performing foreign key checks, InnoDB sets shared row level locks on child or parent records it has to look at. InnoDB checks foreign key constraints immediately; the check is not deferred to transaction commit.

To make it easier to reload dump files for tables that have foreign key relationships, **mysqldump** automatically includes a statement in the dump output to set FOREIGN_KEY_CHECKS to 0 as of MySQL 4.1.1. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. For earlier versions, you can disable the variable manually within **mysql** when loading the dump file like this:

```

mysql> SET FOREIGN_KEY_CHECKS = 0;
mysql> SOURCE dump_file_name
mysql> SET FOREIGN_KEY_CHECKS = 1;

```

This allows you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. FOREIGN_KEY_CHECKS is

available starting from MySQL 3.23.52 and 4.0.3.

Setting `FOREIGN_KEY_CHECKS` to 0 can also be useful for ignoring foreign key constraints during `LOAD DATA` or `ALTER TABLE` operations.

InnoDB does not allow you to drop a table that is referenced by a `FOREIGN KEY` constraint, unless you do `SET FOREIGN_KEY_CHECKS=0`. When you drop a table, the constraints that were defined in its create statement are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the right column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns error number 1005 and refers to `errno 150` in the error message string.

15.7.5. InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the table type on the slave is not the same as the original table type on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave.

To set up a new slave for a master, you have to make a copy of the InnoDB tablespace and the log files, as well as the `.frm` files of the InnoDB tables, and move the copies to the slave. For the proper procedure to do this, see Section 15.10, “Moving an InnoDB Database to Another Machine”.

If you can shut down the master or an existing slave, you can take a cold backup of the InnoDB tablespace and log files and use that to set up a slave. To make a new slave without taking down any server you can also use the non-free (commercial) InnoDB Hot Backup tool [<http://www.innodb.com/order.html>].

There are minor limitations in InnoDB replication:

- `LOAD TABLE FROM MASTER` does not work for InnoDB type tables. There are workarounds: 1) dump the table on the master and import the dump file into the slave, or 2) use `ALTER TABLE tbl_name TYPE=MyISAM` on the master before setting up replication with `LOAD TABLE tbl_name FROM MASTER`, and then use `ALTER TABLE` to alter the master table back to the InnoDB type afterward.
- Before MySQL 4.0.6, `SLAVE STOP` did not respect the boundary of a multiple-statement transaction. An incomplete transaction would be rolled back, and the next `SLAVE START` would only execute the remaining part of the half transaction. That would cause replication to fail.
- Before MySQL 4.0.6, a slave crash in the middle of a multiple-statement transaction would cause the same problem as `SLAVE STOP`.
- Before MySQL 4.0.11, replication of the `SET FOREIGN_KEY_CHECKS=0` statement does not work properly.

Most of these limitations can be eliminated by using more recent server versions for which the limitations do not apply.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A slave reads the binary log of the master and executes the same SQL statements. However, statements that occur within a transaction are not written to the binary log until the transaction commits, at which point all statements in the transaction are written at once. If a statement fails, for example, because of a foreign key violation, or if a transaction is rolled back, no SQL statements are written to the binary log, and the transaction is not executed on the slave at all.

15.7.6. Using Per-Table Tablespaces

NOTE: A bug in versions $\leq 4.1.8$ if you specify `innodb_file_per_table` in `my.cnf`! If you shut down **mysqld**, then records may disappear from the secondary indexes of a table. See (Bug #7496 [<http://bugs.mysql.com/7496>]) for more information and workarounds. This is fixed in 4.1.9, but another bug (Bug #8021 [<http://bugs.mysql.com/8021>]) bit the Windows version in 4.1.9, and in the Windows version of 4.1.9 you must put the line `innodb_flush_method=unbuffered` to your `my.cnf` or `my.ini` to get **mysqld** to work.

Starting from MySQL 4.1.1, you can store each InnoDB table and its indexes into its own file. This feature is called "multiple tablespaces" because in effect each table has its own tablespace.

Using multiple tablespaces can be beneficial to users who want to move specific tables to separate physical disks or who wish to restore backups of single tables quickly without interrupting the use of the remaining InnoDB tables.

If you need to downgrade to 4.0, you have to take table dumps and re-create the whole InnoDB tablespace. If you have not created new InnoDB tables under MySQL 4.1.1 or later, and need to downgrade quickly, you can also do a direct downgrade to the MySQL 4.0.18 or later in the 4.0 series. Before doing the direct downgrade to 4.0.x, you have to end all client connections to the **mysqld** server that is to be downgraded, and let it run the purge and insert buffer merge operations to completion, so that `SHOW INNODB STATUS` shows the main thread in the state `waiting for server activity`. Then you can shut down **mysqld** and start 4.0.18 or later in the 4.0 series.

You can enable multiple tablespaces by adding a line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table
```

After restarting the server, InnoDB stores each newly created table into its own file `tbl_name.ibd` in the database directory where the table belongs. This is similar to what the MyISAM storage engine does, but MyISAM divides the table into a data file `tbl_name.MYD` and the index file `tbl_name.MYI`. For InnoDB, the data and the indexes are stored together in the `.ibd` file. The `tbl_name.frm` file is still created as usual.

If you remove the `innodb_file_per_table` line from `my.cnf` and restart the server, InnoDB creates tables inside the shared tablespace files again.

`innodb_file_per_table` affects only table creation. If you start the server with this option, new tables are created using `.ibd` files, but you can still access tables that exist in the shared tablespace. If you remove the option, new tables are created in the shared tablespace, but you can still access any tables that were created using multiple tablespaces.

InnoDB always needs the shared tablespace. The `.ibd` files are not sufficient for InnoDB to operate. The shared tablespace consists of the familiar `ibdata` files where InnoDB puts its internal data dictionary and undo logs.

You cannot freely move `.ibd` files around between database directories the way you can with MyISAM table files. This is because the table definition is stored in the InnoDB shared tablespace, and also because InnoDB must preserve the consistency of transaction IDs and log sequence numbers.

Within a given MySQL installation, you can move an `.ibd` file and the associated table from one database to another with the familiar `RENAME TABLE` statement:

```
RENAME TABLE old_db_name.tbl_name TO new_db_name.tbl_name ;
```

If you have a "clean" backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. Issue this `ALTER TABLE` statement:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

Caution: This deletes the current `.ibd` file.

2. Put the backup `.ibd` file back in the proper database directory.
3. Issue this `ALTER TABLE` statement:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

In this context, a ``clean" `.ibd` file backup means:

- There are no uncommitted modifications by transactions in the `.ibd` file.
- There are no unmerged insert buffer entries in the `.ibd` file.
- Purge has removed all delete-marked index records from the `.ibd` file.
- **mysqld** has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make such a clean backup `.ibd` file with the following method:

1. Stop all activity from the **mysqld** server and commit all transactions.
2. Wait until `SHOW INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of InnoDB is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the commercial InnoDB Hot Backup tool:

1. Use InnoDB Hot Backup to back up the InnoDB installation.
2. Start a second **mysqld** server on the backup and let it clean up the `.ibd` files in the backup.

It is in the TODO to also allow moving clean `.ibd` files to another MySQL installation. This requires resetting of transaction IDs and log sequence numbers in the `.ibd` file.

15.8. Adding and Removing InnoDB Data and Log Files

This section describes what you can do when your InnoDB tablespace runs out of room or when you want to change the size of the log files.

From MySQL 3.23.50 and 4.0.2, the easiest way to increase the size of the InnoDB tablespace is to configure it from the beginning to be auto-extending. Specify the `autoextend` attribute for the last data file in the tablespace definition. Then InnoDB increases the size of that file automatically in 8MB increments when it runs out of space. Starting with MySQL 4.0.24 and 4.1.5, the increment size can be configured with the option `innodb_autoextend_increment`, in megabytes. The default value is 8.

Alternatively, you can increase the size of your tablespace by adding another data file. To do this, you have to shut down the MySQL server, edit the `my.cnf` file to add a new data file to the end of

`innodb_data_file_path`, and start the server again.

If your last data file was defined with the keyword `autoextend`, the procedure to edit `my.cnf` must take into account the size to which the last data file has grown. You have to look at the size of the data file, round the size downward to the closest multiple of $1024 * 1024$ bytes (= 1MB), and specify the rounded size explicitly in `innodb_data_file_path`. Then you can add another data file. Remember that only the last data file in the `innodb_data_file_path` can be specified as auto-extending.

As an example, assume that the tablespace has just one auto-extending data file `ibdata1`:

```
innodb_data_home_dir =  
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Below is the configuration line after adding another auto-extending data file.

```
innodb_data_home_dir =  
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When you add a new file to the tablespace, make sure that it does not exist. InnoDB creates and initializes the file when you restart the server.

Currently, you cannot remove a data file from the tablespace. To decrease the size of your tablespace, use this procedure:

1. Use **mysqldump** to dump all your InnoDB tables.
2. Stop the server.
3. Remove all the existing tablespace files.
4. Configure a new tablespace.
5. Restart the server.
6. Import the dump files.

If you want to change the number or the size of your InnoDB log files, you have to stop the MySQL server and make sure that it shuts down without errors. Then copy the old log files into a safe place just in case something went wrong in the shutdown and you need them to recover the tablespace. Delete the old log files from the log file directory, edit `my.cnf` to change the log file configuration, and start the MySQL server again. **mysqld** sees that no log files exist at startup and tells you that it is creating new ones.

15.9. Backing Up and Recovering an InnoDB Database

The key to safe database management is taking regular backups.

InnoDB Hot Backup is an online backup tool you can use to backup your InnoDB database while it is running. InnoDB Hot Backup does not require you to shut down your database and it does not set any locks or disturb your normal database processing. InnoDB Hot Backup is a non-free (commercial) additional tool whose annual license fee is 390 euros per computer where the MySQL server is run. See the InnoDB Hot Backup home page [<http://www.innodb.com/order.html>] for detailed information and screenshots.

If you are able to shut down your MySQL server, you can make a "binary" backup that consists of all files used by InnoDB to manage its tables. Use the following procedure:

1. Shut down your MySQL server and make sure that it shuts down without errors.
2. Copy all your data files (`ibdata` files, `.ibd` files) into a safe place.
3. Copy all your `ib_logfiles` to a safe place.
4. Copy your `my.cnf` configuration file or files to a safe place.
5. Copy all the `.frm` files for your InnoDB tables to a safe place.

Replication works with InnoDB type tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability.

In addition to taking binary backups as just described, you should also regularly take dumps of your tables with **mysqldump**. The reason for this is that a binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, since the format is simpler, the chance for serious data corruption is smaller. **mysqldump** also has a `--single-transaction` option that you can use to take a consistent snapshot without locking out other clients.

To be able to recover your InnoDB database to the present from the binary backup described above, you have to run your MySQL server with binary logging turned on. Then you can apply the binary log to the backup database to achieve point-in-time recovery:

```
mysqlbinlog yourhostname-bin.123 | mysql
```

To recover from a crash of your MySQL server process, the only thing you have to do is to restart it. InnoDB automatically checks the logs and performs a roll-forward of the database to the present. InnoDB automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, **mysqld** displays output something like this:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

If your database gets corrupted or your disk fails, you have to do the recovery from a backup. In the case of corruption, you should first find a backup that is not corrupted. After restoring the base backup, do the recovery from the binary log files.

In some cases of database corruption it is enough just to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE SQL` statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption. You can use `innodb_tablespace_monitor` to check the integrity of the file space management inside the tablespace files.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best first to try restarting your computer. It may eliminate errors that appeared to be database page corruption.

15.9.1. Forcing Recovery

If there is database page corruption, you may want to dump your tables from the database with `SELECT INTO OUTFILE`, and usually most of the data is intact and correct. But the corruption may cause `SELECT * FROM tbl_name` or InnoDB background operations to crash or assert, or even the InnoDB roll-forward recovery to crash. Starting from MySQL 3.23.44, there is an InnoDB variable that you can use to force the InnoDB storage engine to start up, and you can also prevent background operations from running, so that you are able to dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 4
```

Before MySQL 4.0, use this syntax instead:

```
[mysqld]
set-variable = innodb_force_recovery=4
```

The allowable non-zero values for `innodb_force_recovery` follow. A larger number includes all precautions of lower numbers. If you are able to dump your tables with an option value of at most 4, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 6 is more dramatic, because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

- 1 (`SRV_FORCE_IGNORE_CORRUPT`)
Let the server run even if it detects a corrupt page; try to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.
- 2 (`SRV_FORCE_NO_BACKGROUND`)
Prevent the main thread from running. If a crash would occur in the purge operation, this prevents it.
- 3 (`SRV_FORCE_NO_TRX_UNDO`)
Do not run transaction rollbacks after recovery.
- 4 (`SRV_FORCE_NO_IBUF_MERGE`)
Prevent also insert buffer merge operations. If they would cause a crash, better not do them; do not calculate table statistics.
- 5 (`SRV_FORCE_NO_UNDO_LOG_SCAN`)
Do not look at undo logs when starting the database: InnoDB treats even incomplete transactions as committed.
- 6 (`SRV_FORCE_NO_LOG_REDO`)
Do not do the log roll-forward in connection with recovery.

The database must not otherwise be used with any of these options enabled! As a safety measure, InnoDB prevents users from doing `INSERT`, `UPDATE`, or `DELETE` when `innodb_force_recovery` is set to a value greater than 0.

Starting from MySQL 3.23.53 and 4.0.4, you are allowed to `DROP` or `CREATE` a table even if forced recovery is used. If you know that a certain table is causing a crash in rollback, you can drop it. You can use this also to stop a runaway rollback caused by a failing mass import or `ALTER TABLE`. You can kill the `mysqld` process and set `innodb_force_recovery` to 3 to bring your database up without the rollback. Then `DROP` the table that is causing the runaway rollback.

15.9.2. Checkpoints

InnoDB implements a checkpoint mechanism called a "fuzzy checkpoint." InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would in practice stop processing of user SQL statements for a while.

In crash recovery, InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the place of the checkpoint, applying the logged modifications to the database.

InnoDB writes to the log files in a circular fashion. All committed modifications that make the database pages in the buffer pool different from the images on disk must be available in the log files in case InnoDB has to do a recovery. This means that when InnoDB starts to reuse a log file in the circular fashion, it has to make sure that the database page images on disk contain the modifications logged in the log file InnoDB is going to reuse. In other words, InnoDB has to make a checkpoint and often this involves flushing of modified database pages to disk.

The preceding description explains why making your log files very big may save disk I/O in checkpointing. It can make sense to set the total size of the log files as big as the buffer pool or even bigger. The drawback of big log files is that crash recovery can take longer because there is more logged information to apply to the database.

15.10. Moving an InnoDB Database to Another Machine

On Windows, InnoDB internally always stores database and table names in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, you should have all table and database names in lowercase. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` before you start creating your databases and tables:

```
[mysqld]
set-variable = lower_case_table_names=1
```

Like MyISAM data files, InnoDB data and log files are binary-compatible on all platforms if the floating-point number format on the machines is the same. You can move an InnoDB database simply by copying all the relevant files, which were listed in Section 15.9, "Backing Up and Recovering an InnoDB Database". If the floating-point formats on the machines are different but you have not used `FLOAT` or `DOUBLE` data types in your tables, then the procedure is the same: Just copy the relevant files. If the formats are different and your tables contain floating-point data, you have to use `mysqldump` to dump your tables on one machine and then import the dump files on the other machine.

A performance tip is to switch off autocommit mode when you import data into your database, assuming that your tablespace has enough space for the big rollback segment the the big import transactions generate. Do the commit only after importing a whole table or a segment of a table.

15.11. InnoDB Transaction Model and Locking

In the InnoDB transaction model, the goal has been to combine the best properties of a multi-

versioning database with traditional two-phase locking. InnoDB does locking on the row level and runs queries as non-locking consistent reads by default, in the style of Oracle. The lock table in InnoDB is stored so space-efficiently that lock escalation is not needed: Typically several users are allowed to lock every row in the database, or any random subset of the rows, without InnoDB running out of memory.

15.11.1. InnoDB Lock Modes

InnoDB implements standard row level locking where there are two types of locks:

- Shared (*S*) allows a transaction to read a row.
- Exclusive (*X*) allows a transaction to update or delete a row.

If a transaction *A* holds an exclusive (*X*) lock on tuple *t*, then a request from some distinct transaction *B* for a lock either type on *t* cannot be immediately granted. Instead the transaction *B* has to wait for the transaction *A* to release lock on tuple *t*.

If transaction *A* holds a shared (*S*) lock on tuple *t*, then

- A request from some distinct transaction *B* for an *X* lock on *t* cannot be immediately granted.
- A request from some distinct transaction *B* for an *S* lock on *t* can be immediately granted. Thus now both *A* and *B* holds an *S* lock on *t*.

Additionally, InnoDB supports *multiple granularity locking* which allows coexistence of record locks and locks on entire tables. To make multiple granularity level locking practical, additional types of locks, called *intention locks* are used. Intention locks are table locks in the InnoDB. The idea behind intention locks is for a transaction to indicate what type of lock (shared or exclusive) it will require later to a row in that table. There are two types of intention locks used in the InnoDB (assume that transaction *T* has requested a lock of the indicated type on table *R*):

- Intent shared (*IS*): Transaction *T* intends to set *S* locks on individual tuples to table *T*.
- Intention exclusive (*IX*): Transaction *T* intends to set *X* locks on those tuples.

Thus, intent locking protocol is as follows:

- Before a given transaction can acquire an *S* lock on a given row, it must first acquire an *IS* or stronger lock on the table containing that row.
- Before a given transaction can acquire an *X* lock on a given row, it must first acquire an *IX* lock on the table containing that row.

These rules can be conveniently summarized by means of a *lock type compatibility matrix*:

	X	IX	S	IS	-
X	N	N	N	N	Y
IX	N	Y	N	Y	Y
S	N	Y	Y	Y	Y
IS	N	Y	Y	Y	Y
-	Y	Y	Y	Y	Y

Thus, intention locks do not block anything except full table requests (e.g. `LOCK TABLES ... WRITE`). The main purpose of `IX` and `IS` is to show that someone is locking a row, or going to lock a row in the table.

15.11.2. InnoDB and AUTOCOMMIT

In InnoDB, all user activity occurs inside a transaction. If the autocommit mode is enabled, each SQL statement forms a single transaction on its own. MySQL always starts a new connection with autocommit enabled.

If the autocommit mode is switched off with `SET AUTOCOMMIT = 0`, then we can consider that a user always has a transaction open. A SQL `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts. Both statements release all InnoDB locks that were set during the current transaction. A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other users. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction.

If the connection has autocommit enabled, the user can still perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with `COMMIT` or `ROLLBACK`.

15.11.3. InnoDB and TRANSACTION ISOLATION LEVEL

In terms of the SQL:1992 transaction isolation levels, the InnoDB default is `REPEATABLE READ`. Starting from MySQL 4.0.5, InnoDB offers all four different transaction isolation levels described by the SQL standard. You can set the default isolation level for all connections by using the `--transaction-isolation` option on the command line or in option files. For example, you can set the option in the `[mysqld]` section of `my.cnf` like this:

```
[mysqld]
transaction-isolation = {READ-UNCOMMITTED | READ-COMMITTED
                        | REPEATABLE-READ | SERIALIZABLE}
```

A user can change the isolation level of a single session or all new incoming connections with the `SET TRANSACTION` statement. Its syntax is as follows:

```
SET [SESSION | GLOBAL] TRANSACTION ISOLATION LEVEL
    {READ UNCOMMITTED | READ COMMITTED
     | REPEATABLE READ | SERIALIZABLE}
```

Note that there are hyphens in the level names for the `--transaction-isolation` option, but not for the `SET TRANSACTION` statement.

The default behavior is to set the isolation level for the next (not started) transaction. If you use the `GLOBAL` keyword, the statement sets the default transaction level globally for all new connections created from that point on (but not existing connections). You need the `SUPER` privilege to do this. Using the `SESSION` keyword sets the default transaction level for all future transactions performed on the current connection.

Any client is free to change the session isolation level (even in the middle of a transaction), or the isolation level for the next transaction.

Before MySQL 3.23.50, `SET TRANSACTION` had no effect on InnoDB tables. Before 4.0.5, only `REPEATABLE READ` and `SERIALIZABLE` were available.

You can query the global and session transaction isolation levels with these statements:

```
SELECT @@global.tx_isolation;
SELECT @@tx_isolation;
```

In row-level locking, InnoDB uses so-called "next-key locking." That means that besides index records, InnoDB can also lock the "gap" before an index record to block insertions by other users immediately before the index record. A next-key lock refers to a lock that locks an index record and the gap before it. A gap lock refers to a lock that only locks a gap before some index record.

A detailed description of each isolation level in InnoDB:

- `READ UNCOMMITTED`

`SELECT` statements are performed in a non-locking fashion, but a possible earlier version of a record might be used. Thus, using this isolation level, such reads are not "consistent." This is also called "dirty read." Other than that, this isolation level works like `READ COMMITTED`.

- `READ COMMITTED`

A somewhat Oracle-like isolation level. All `SELECT ... FOR UPDATE` and `SELECT ... LOCK IN SHARE MODE` statements lock only the index records, not the gaps before them, and thus allow free inserting of new records next to locked records. `UPDATE` and `DELETE` statements that use a unique index with a unique search condition lock only the index record found, not the gap before it. In range-type `UPDATE` and `DELETE` statements, InnoDB must set next-key or gap locks and block insertions by other users to the gaps covered by the range. This is necessary because "phantom rows" must be blocked for MySQL replication and recovery to work.

Consistent reads behave as in Oracle: Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. See Section 15.11.4, "Consistent Non-Locking Read".

- `REPEATABLE READ`

This is the default isolation level of InnoDB. `SELECT ... FOR UPDATE`, `SELECT ... LOCK IN SHARE MODE`, `UPDATE`, and `DELETE` statements that use a unique index with a unique search condition lock only the index record found, not the gap before it. With other search conditions, these operations employ next-key locking, locking the index range scanned with next-key or gap locks, and block new insertions by other users.

In consistent reads, there is an important difference from the previous isolation level: In this level, all consistent reads within the same transaction read the same snapshot established by the first read. This convention means that if you issue several plain `SELECT` statements within the same transaction, these `SELECT` statements are consistent also with respect to each other. See Section 15.11.4, "Consistent Non-Locking Read".

- `SERIALIZABLE`

This level is like `REPEATABLE READ`, but all plain `SELECT` statements are implicitly converted to `SELECT ... LOCK IN SHARE MODE`.

15.11.4. Consistent Non-Locking Read

A consistent read means that InnoDB uses its multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by exactly those transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by the transaction itself that issues the query.

If you are running with the default `REPEATABLE READ` isolation level, then all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

Consistent read is the default mode in which InnoDB processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other users are free to modify those tables at the same time a

consistent read is being performed on the table.

15.11.5. Locking Reads `SELECT ... FOR UPDATE` and `SELECT ... LOCK IN SHARE MODE`

In some circumstances, a consistent read is not convenient. For example, you might want to add a new row into your table `child`, and make sure that the child has a parent in table `parent`. The following example shows how to implement referential integrity in your application code.

Suppose that you use a consistent read to read the table `parent` and indeed see the parent of the child in the table. Can you safely add the child row to table `child`? No, because it may happen that meanwhile some other user deletes the parent row from the table `parent`, without you being aware of it.

The solution is to perform the `SELECT` in a locking mode using `LOCK IN SHARE MODE`:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

Performing a read in share mode means that we read the latest available data, and set a shared mode lock on the rows we read. A shared mode lock prevents others from updating or deleting the row we have read. Also, if the latest data belongs to a yet uncommitted transaction of another client connection, we wait until that transaction commits. After we see that the preceding query returns the parent 'Jones', we can safely add the child record to the `child` table and commit our transaction.

Let us look at another example: We have an integer counter field in a table `child_codes` that we use to assign a unique identifier to each child added to table `child`. Obviously, using a consistent read or a shared mode read to read the present value of the counter is not a good idea, since two users of the database may then see the same value for the counter, and a duplicate-key error occurs if two users attempt to add children with the same identifier to the table.

Here, `LOCK IN SHARE MODE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when attempting to update the counter.

In this case, there are two good ways to implement the reading and incrementing of the counter: (1) update the counter first by incrementing it by 1 and only after that read it, or (2) read the counter first with a lock mode `FOR UPDATE`, and increment after that. The latter approach can be implemented as follows:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus it sets the same locks a searched `SQL UPDATE` would set on the rows.

Please note that the above is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

15.11.6. Next-Key Locking: Avoiding the Phantom Problem

In row-level locking, InnoDB uses an algorithm called "next-key locking." InnoDB does the row-level locking in such a way that when it searches or scans an index of a table, it sets shared or ex-

clusive locks on the index records it encounters. Thus the row-level locks are actually index record locks.

The locks InnoDB sets on index records also affect the "gap" before that index record. If a user has a shared or exclusive lock on record R in an index, another user cannot insert a new index record immediately before R in the index order. This locking of gaps is done to prevent the so-called "phantom problem." Suppose that you want to read and lock all children from the `child` table with an identifier value larger than 100, with the intent of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

Suppose that there is an index on the `id` column. The query scans that index starting from the first record where `id` is bigger than 100. If the locks set on the index records would not lock out inserts made in the gaps, a new row might meanwhile be inserted to the table. If you execute the same `SELECT` within the same transaction, you would see a new row in the result set returned by the query. This is contrary the isolation principle of transactions: A transaction should be able to run so that the data it has read does not change during the transaction. If we regard a set of rows as a data item, the new "phantom" child would violate this isolation principle.

When InnoDB scans an index, it can also lock the gap after the last record in the index. Just that happens in the previous example: The locks set by InnoDB prevent any insert to the table where `id` would be bigger than 100.

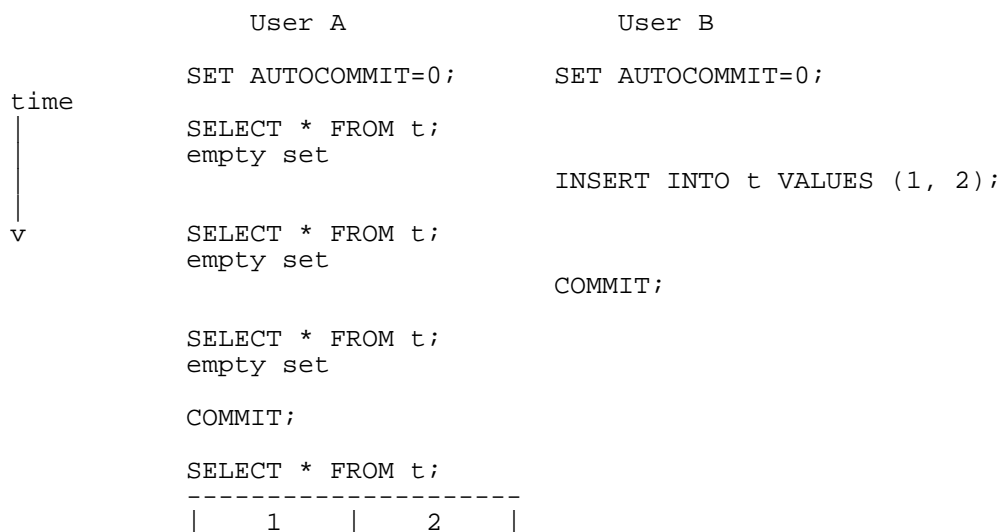

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus the next-key locking allows you to "lock" the non-existence of something in your table.

15.11.7. An Example of How the Consistent Read Works in InnoDB

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read, that is, an ordinary `SELECT` statement, InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

You can advance your timepoint by committing your transaction and then doing another `SELECT`.

This is called "multi-versioned concurrency control."

```
-----
1 row in set
```

In this example, user A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

If you want to see the “freshest” state of the database, you should use either the `READ COMMITTED` isolation level or a locking read:

```
SELECT * FROM t LOCK IN SHARE MODE;
```

15.11.8. Locks Set by Different SQL Statements in InnoDB

A locking read, an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of the SQL query. It does not matter if there are `WHERE` conditions in the query that would exclude the row from the result set of the query. InnoDB does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The record locks are normally next-key locks that also block inserts to the “gap” immediately before the record.

If the locks to be set are exclusive, then InnoDB always retrieves also the clustered index record and sets a lock on it.

If you do not have indexes suitable for your query and MySQL has to scan the whole table to process the query, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily need to scan many rows.

- `SELECT ... FROM` is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to `SERIALIZABLE`. For `SERIALIZABLE` level, this sets shared next-key locks on the index records it encounters.
- `SELECT ... FROM ... LOCK IN SHARE MODE` sets shared next-key locks on all index records the read encounters.
- `SELECT ... FROM ... FOR UPDATE` sets exclusive next-key locks on all index records the read encounters.
- `INSERT INTO ... VALUES (...)` sets an exclusive lock on the inserted row. Note that this lock is not a next-key lock and does not prevent other users from inserting to the gap before the inserted row. If a duplicate-key error occurs, a shared lock on the duplicate index record is set.
- While initializing a previously specified `AUTO_INCREMENT` column on a table, InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, InnoDB uses a specific table lock mode `AUTO-INC` where the lock lasts only to the end of the current SQL statement, instead of to the end of the whole transaction. See Section 15.11.2, “InnoDB and `AUTOCOMMIT`”.

Before MySQL 3.23.50, `SHOW TABLE STATUS` applied to a table with an `AUTO_INCREMENT` column sets an exclusive row-level lock to the high end of the `AUTO_INCREMENT` index. This means also that `SHOW TABLE STATUS` could cause a deadlock of transactions, something that may surprise users. Starting from MySQL 3.23.50, InnoDB fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

- `INSERT INTO T SELECT ... FROM S WHERE ...` sets an exclusive (non-next-key) lock on each row inserted into T. It does the search on S as a consistent read, but sets shared next-key locks on S if MySQL binary logging is turned on. InnoDB has to set locks in the latter

case: In roll-forward recovery from a backup, every SQL statement has to be executed in exactly the same way it was done originally.

- `CREATE TABLE ... SELECT ...` performs the `SELECT` as a consistent read or with shared locks, as in the previous item.
- `REPLACE` is done like an insert if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row that has to be updated.
- `UPDATE ... WHERE ...` sets an exclusive next-key lock on every record the search encounters.
- `DELETE FROM ... WHERE ...` sets an exclusive next-key lock on every record the search encounters.
- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires checking of the constraint condition sets shared record-level locks on the records it looks at to check the constraint. InnoDB also sets these locks in the case where the constraint fails.
- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the InnoDB layer that sets these locks. Beginning with MySQL 4.0.20 and 4.1.2, InnoDB is aware of table locks if `innodb_table_locks=1` and `AUTOCOMMIT=0`, and the MySQL layer above InnoDB knows about row-level locks. Before that, the automatic deadlock detection of InnoDB cannot detect deadlocks where such table locks are involved. Also, since the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another user currently has row-level locks. But that does not put transaction integrity in danger. See Section 15.11.10, “Deadlock Detection and Rollback”. See Section 15.17, “Restrictions on InnoDB Tables”.

15.11.9. When Does MySQL Implicitly Commit or Roll Back a Transaction?

MySQL begins each client connection with autocommit mode enabled by default. When autocommit is enabled, MySQL does a commit after each SQL statement if that statement did not return an error.

If you have the autocommit mode off and close a connection without calling an explicit commit of your transaction, then MySQL rolls back your transaction.

If an SQL statement returns an error, the commit/rollback behavior depends on the error. See Section 15.16, “Error Handling”.

The following SQL statements (and any synonyms for them) cause an implicit commit of the current transaction in MySQL:

- `ALTER TABLE`, `BEGIN`, `CREATE INDEX`, `DROP DATABASE`, `DROP INDEX`, `DROP TABLE`, `LOAD MASTER DATA`, `LOCK TABLES`, `RENAME TABLE`, `SET AUTOCOMMIT=1`, `START TRANSACTION`, `TRUNCATE`, `UNLOCK TABLES`.
- `CREATE TABLE` (this commits only if before MySQL 4.0.13 and MySQL binary logging is used).
- The `CREATE TABLE` statement in InnoDB is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

15.11.10. Deadlock Detection and Rollback

InnoDB automatically detects a deadlock of transactions and rolls back a transaction or transactions to prevent the deadlock. Starting from MySQL 4.0.5, InnoDB tries to pick small transactions to roll back. The size of a transaction is determined by the number of rows it has inserted, updated, or deleted. Prior to 4.0.5, InnoDB always rolled back the transaction whose lock request was the last one to build a deadlock, that is, a cycle in the "waits-for" graph of transactions.

Beginning with MySQL 4.0.20 and 4.1.2, InnoDB is aware of table locks if `innodb_table_locks=1` (1 is the default), and the MySQL layer above InnoDB knows about row-level locks. Before that, InnoDB cannot detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement is involved, or if a lock set by another storage engine than InnoDB is involved. You have to resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

When InnoDB performs a complete rollback of a transaction, all the locks of the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the locks set by the SQL statement may be preserved. This is because InnoDB stores row locks in a format such it cannot know afterward which lock was set by which SQL statement.

15.11.11. How to Cope with Deadlocks

Deadlocks are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really "atomic"; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- Use `SHOW INNODB STATUS` to determine the cause of the latest deadlock. That can help you to tune your application to avoid deadlocks. This strategy can be used as of MySQL 3.23.52 and 4.0.3, depending on your MySQL series.
- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Commit your transactions often. Small transactions are less prone to collide.
- If you are using locking reads (`SELECT ... FOR UPDATE` or `... LOCK IN SHARE MODE`), try using a lower isolation level such as `READ COMMITTED`.
- Access your tables and rows in a fixed order. Then transactions form nice queues and do not deadlock.
- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.
- Use less locking. If you can afford to allow a `SELECT` to return data from an old snapshot, do not add the clause `FOR UPDATE` or `LOCK IN SHARE MODE` to it. Using `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
- If nothing helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, like InnoDB, is to set `AUTOCOMMIT = 0` and not to call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write table `t1` and read table `t2`, you can do this:

```
SET AUTOCOMMIT=0;
```

```
LOCK TABLES t1 WRITE, t2 READ, ...;
[do something with tables t1 and t2 here];
COMMIT;
UNLOCK TABLES;
```

Table-level locks make your transactions queue nicely, and deadlocks are avoided.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the InnoDB instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.
- In applications using `AUTOCOMMIT=1` and MySQL's `LOCK TABLES` command, InnoDB's internal table locks that were present from 4.0.20 to 4.0.23 can cause deadlocks. Starting from 4.0.22, you can set `innodb_table_locks=0` in `my.cnf` to fall back to the old behavior and remove the problem. 4.0.24 does not set InnoDB table locks if `AUTOCOMMIT=1`.

15.12. InnoDB Performance Tuning Tips

- If the Unix `top` tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound. Maybe you are making too many transaction commits, or the buffer pool is too small. Making the buffer pool bigger can help, but do not set it bigger than 80% of physical memory.
- Wrap several modifications into one transaction. InnoDB must flush the log to disk at each transaction commit if that transaction made modifications to the database. Since the rotation speed of a disk is typically at most 167 revolutions/second, that constrains the number of commits to the same 167th/second if the disk does not fool the operating system.
- If you can afford the loss of some of the latest committed transactions, you can set the `my.cnf` parameter `innodb_flush_log_at_trx_commit` to 0. InnoDB tries to flush the log once per second anyway, although the flush is not guaranteed.
- Make your log files big, even as big as the buffer pool. When InnoDB has written the log files full, it has to write the modified contents of the buffer pool to disk in a checkpoint. Small log files cause many unnecessary disk writes. The drawback of big log files is that the recovery time is longer.
- Make the log buffer quite big as well (say, 8MB).
- Use the `VARCHAR` column type instead of `CHAR` if you are storing variable-length strings or if the column may contain many `NULL` values. A `CHAR(N)` column always takes `N` bytes to store data, even if the string is shorter or its value is `NULL`. Smaller tables fit better in the buffer pool and reduce disk I/O.
- (Relevant from 3.23.39 up.) In some versions of GNU/Linux and Unix, flushing files to disk with the Unix `fsync()` and other similar methods is surprisingly slow. The default method InnoDB uses is the `fsync()` function. If you are not satisfied with the database write performance, you might try setting `innodb_flush_method` in `my.cnf` to `O_DSYNC`, although `O_DSYNC` seems to be slower on most systems.
- (Verified using MySQL 4.1, assumed for other MySQL versions, given that this is a platform architecture issue.) When using the InnoDB storage engine on Solaris 10 for `x86_64` architecture (AMD Opteron), it is important to mount any filesystems used for storing InnoDB-related files using the `forcedirectio` option. (The default on Solaris 10/`x86_64` is **not** to use this filesystem mounting option.) Failing to use `forcedirectio` will cause a serious degradation of InnoDB's speed and performance on this platform.

- When importing data into InnoDB, make sure that MySQL does not have autocommit mode enabled because that would require a log flush to disk for every insert. To disable autocommit during your import operation, surround it with `SET AUTOCOMMIT` and `COMMIT` statements:

```
SET AUTOCOMMIT=0;
/* SQL import statements ... */
COMMIT;
```

If you use the `mysqldump` option `--opt`, you get dump files that are fast to import into an InnoDB table, even without wrapping them with the `SET AUTOCOMMIT` and `COMMIT` statements.

- Beware of big rollbacks of mass inserts: InnoDB uses the insert buffer to save disk I/O in inserts, but no such mechanism is used in a corresponding rollback. A disk-bound rollback can take 30 times the time of the corresponding insert. Killing the database process does not help because the rollback starts again at the server startup. The only way to get rid of a runaway rollback is to increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or to use a special procedure. See Section 15.9.1, “Forcing Recovery”.
- Beware also of other big disk-bound operations. Use `DROP TABLE + CREATE TABLE` to empty a table, not `DELETE FROM tbl_name`.
- Use the multiple-row `INSERT` syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table type, not just InnoDB.

- If you have `UNIQUE` constraints on secondary keys, starting from MySQL 3.23.52 and 4.0.3, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```
SET UNIQUE_CHECKS=0;
```

For big tables, this saves a lot of disk I/O because InnoDB can use its insert buffer to write secondary index records in a batch.

- If you have `FOREIGN KEY` constraints in your tables, starting from MySQL 3.23.52 and 4.0.3, you can speed up table imports by turning the foreign key checks off for a while in the import session:

```
SET FOREIGN_KEY_CHECKS=0;
```

For big tables, this can save a lot of disk I/O.

- If you often have recurring queries to tables that are not updated frequently, use the query cache available as of MySQL 4.0:

```
[mysqld]
query_cache_type = ON
query_cache_size = 10M
```

In MySQL 4.0, the query cache works only with autocommit enabled. This restriction is removed in MySQL 4.1.1 and up.

15.12.1. SHOW INNODB STATUS and the InnoDB Monit-

ors

Starting from MySQL 3.23.42, InnoDB includes InnoDB Monitors that print information about the InnoDB internal state. Starting from MySQL 3.23.52 and 4.0.3, you can use the SQL statement `SHOW INNODB STATUS` to fetch the output of the standard InnoDB Monitor to your SQL client. The information is useful in performance tuning. If you are using the `mysql` interactive SQL client, the output is more readable if you replace the usual semicolon statement terminator by `\G`: For a discussion about the InnoDB lock modes see Section 15.11.1, “InnoDB Lock Modes”.

```
mysql> SHOW INNODB STATUS\G
```

Another way to use InnoDB Monitors is to let them continuously write data to the standard output of the server `mysqld`. In this case, no output is sent to clients. When switched on, InnoDB Monitors print data about every 15 seconds. Server output usually is directed to the `.err` log in the MySQL data directory. This data is useful in performance tuning. On Windows, you must start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

Monitor output includes information of the following types:

- Table and record locks held by each active transaction
- Lock waits of a transactions
- Semaphore waits of threads
- Pending file I/O requests
- Buffer pool statistics
- Purge and insert buffer merge activity of the main InnoDB thread

To cause the standard InnoDB Monitor to write to the standard output of `mysqld`, use the following SQL statement:

```
CREATE TABLE innodb_monitor(a INT) TYPE=InnoDB;
```

The monitor can be stopped by issuing the following statement:

```
DROP TABLE innodb_monitor;
```

The `CREATE TABLE` syntax is just a way to pass a command to the InnoDB engine through the MySQL SQL parser: The only things that matter are the table name `innodb_monitor` and that it be an InnoDB table. The structure of the table is not relevant at all for the InnoDB Monitor. If you shut down the server when the monitor is running, and you want to start the monitor again, you have to drop the table before you can issue a new `CREATE TABLE` statement to start the monitor. This syntax may change in a future release.

In a similar way, you can start `innodb_lock_monitor`, which is otherwise the same as `innodb_monitor` but also prints a lot of lock information. A separate `innodb_tablespace_monitor` prints a list of created file segments existing in the tablespace and also validates the tablespace allocation data structures. Starting from 3.23.44, there is `innodb_table_monitor` with which you can print the contents of the InnoDB internal data dictionary.

A sample of InnoDB Monitor output:

```
mysql> SHOW INNODB STATUS\G
***** 1. row *****
Status:
```

```

Some notes on the output:

- If the TRANSACTIONS section reports lock waits, your application may have lock contention. The output can also help to trace the reasons for transaction deadlocks.
- The SEMAPHORES section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside InnoDB. Contention can be due to heavy parallelism of queries, or problems in operating system thread scheduling. Setting `innodb_thread_concurrency` smaller than the default value of 8 can help in such situations.
- The BUFFER POOL AND MEMORY section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.
- The ROW OPERATIONS section shows what the main thread is doing.

Beginning with MySQL 4.0.19, InnoDB sends diagnostic output to `stderr` or files instead of `stdout` or fixed-size memory buffers, to avoid potential buffer overflow errors. As a side effect, the output of `SHOW INNODB STATUS` is written to a status file every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. This file is created in the MySQL data directory. InnoDB removes the file for a normal shutdown. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, you might want to examine them to see if they contain useful information to the cause of abnormal shutdowns. Beginning with MySQL 4.0.21, the `innodb_status.pid` file is only created if the configuration option `innodb_status_file=1` is set.

15.13. Implementation of Multi-Versioning

Because InnoDB is a multi-versioned database, it must keep information about old versions of rows in the tablespace. This information is stored in a data structure called a rollback segment after an analogous data structure in Oracle.

Internally, InnoDB adds two fields to each row stored in the database. A 6-byte field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated.

InnoDB uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, and they can be discarded only after there is no transaction present for which InnoDB has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

You must remember to commit your transactions regularly, including those transactions that only issue consistent reads. Otherwise, InnoDB cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space need for your rollback segment.

In the InnoDB multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. Only when InnoDB can discard the update undo log record written for the deletion can it also physically remove the corresponding row and its index records from the database. This removal operation is called a purge, and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

In a scenario where the user inserts and deletes rows in smallish batches at about the same rate in the table, it is possible that the purge thread starts to lag behind, and the table grows bigger and bigger, making everything disk-bound and very slow. Even if the table would carry just 10 MB of useful data, it may grow to occupy 10 GB with all the dead rows. In such a case, it would be good to throttle new row operations, and allocate more resources for the purge thread. Starting with MySQL/InnoDB-4.1.6 and 4.0.22, there is a startup option and settable global variable `innodb_max_purge_lag` for exactly this purpose. See Section 15.5, “InnoDB Startup Options”.

15.14. Table and Index Structures

MySQL stores its data dictionary information for tables in `.frm` files in database directories. This is true for all MySQL storage engines. But every InnoDB table also has its own entry in InnoDB internal data dictionaries inside the tablespace. When MySQL drops a table or a database, it has to delete both an `.frm` file or files, and the corresponding entries inside the InnoDB data dictionary. This is the reason why you cannot move InnoDB tables between databases simply by moving the `.frm` files. It is also the reason why `DROP DATABASE` did not work for InnoDB type tables before MySQL 3.23.44.

Every InnoDB table has a special index called the clustered index where the data of the rows is stored. If you define a `PRIMARY KEY` on your table, the index of the primary key is the clustered index.

If you do not define a `PRIMARY KEY` for your table, MySQL picks the first `UNIQUE` index that has only `NOT NULL` columns as the primary key and InnoDB uses it as the clustered index. If there is no such index in the table, InnoDB internally generates a clustered index where the rows are

ordered by the row ID that InnoDB assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus the rows ordered by the row ID are physically in the insertion order.

Accessing a row through the clustered index is fast because the row data is on the same page where the index search leads. If a table is large, the clustered index architecture often saves a disk I/O when compared to the traditional solution. (In many databases, the data is traditionally stored on a different page from the index record.)

In InnoDB, the records in non-clustered indexes (also called secondary indexes) contain the primary key value for the row. InnoDB uses this primary key value to search for the row from the clustered index. Note that if the primary key is long, the secondary indexes use more space.

InnoDB compares CHAR and VARCHAR strings of different lengths such that the remaining length in the shorter string is treated as if padded with spaces.

15.14.1. Physical Structure of an Index

All indexes in InnoDB are B-trees where the index records are stored in the leaf pages of the tree. The default size of an index page is 16KB. When new records are inserted, InnoDB tries to leave 1/16 of the page free for future insertions and updates of the index records.

If index records are inserted in a sequential order (ascending or descending), the resulting index pages is about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full. If the fillfactor of an index page drops below 1/2, InnoDB tries to contract the index tree to free the page.

15.14.2. Insert Buffering

It is a common situation in a database application that the primary key is a unique identifier and new rows are inserted in the ascending order of the primary key. Thus the insertions to the clustered index do not require random reads from a disk.

On the other hand, secondary indexes are usually non-unique, and insertions into secondary indexes happen in a relatively random order. This would cause a lot of random disk I/O operations without a special mechanism used in InnoDB.

If an index record should be inserted to a non-unique secondary index, InnoDB checks whether the secondary index page is in the buffer pool. If that is the case, InnoDB does the insertion directly to the index page. If the index page is not found in the buffer pool, InnoDB inserts the record to a special insert buffer structure. The insert buffer is kept so small that it fits entirely in the buffer pool, and insertions can be done very fast.

Periodically, the insert buffer is merged into the secondary index trees in the database. Often it is possible to merge several insertions to the same page of the index tree, saving disk I/O operations. It has been measured that the insert buffer can speed up insertions into a table up to 15 times.

The insert buffer merging may continue to happen *after* the inserting transaction has been committed. In fact, it may continue to happen after a server shutdown & restart (see Section 15.9.1, “Forcing Recovery”).

The insert buffer merging may take many hours, when many secondary indexes must be updated, and many rows have been inserted. During this time, disk I/O will be increased, which can cause significant slowdown on disk-bound queries. Another significant background I/O operation is the purge thread (see Section 15.13, “Implementation of Multi-Versioning”).

15.14.3. Adaptive Hash Indexes

If a table fits almost entirely in main memory, the fastest way to perform queries on it is to use hash indexes. InnoDB has an automatic mechanism that monitors index searches made to the indexes defined for a table. If InnoDB notices that queries could benefit from building a hash index, it does so automatically.

Note that the hash index is always built based on an existing B-tree index on the table. InnoDB can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches that InnoDB observes for the B-tree index. A hash index can be partial: It is not required that the whole B-tree index is cached in the buffer pool. InnoDB builds hash indexes on demand for those pages of the index that are often accessed.

In a sense, InnoDB tailors itself through the adaptive hash index mechanism to ample main memory, coming closer to the architecture of main memory databases.

15.14.4. Physical Record Structure

Records in InnoDB tables have the following characteristics:

- Each index record in InnoDB contains a header of six bytes. The header is used to link consecutive records together, and also in row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a six-byte field for the transaction ID and a seven-byte field for the roll pointer.
- If no primary key was defined for a table, each clustered index record also contains a six-byte row ID field.
- Each secondary index record contains also all the fields defined for the clustered index key.
- A record contains also a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.
- Internally, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length format. InnoDB truncates trailing spaces from `VARCHAR` columns. Note that MySQL may internally convert `CHAR` columns to `VARCHAR`. See Section 13.2.5.1, “Silent Column Specification Changes”.
- An SQL `NULL` value reserves 1 or 2 bytes in the record directory. Besides that, an SQL `NULL` value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. The motivation behind reserving the fixed space for `NULL` values is that then an update of the column from `NULL` to a non-`NULL` value can be done in place and does not cause fragmentation of the index page.

15.15. File Space Management and Disk I/O

15.15.1. Disk I/O

InnoDB uses simulated asynchronous disk I/O: InnoDB creates a number of threads to take care of I/O operations, such as read-ahead.

There are two read-ahead heuristics in InnoDB:

- In sequential read-ahead, if InnoDB notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if InnoDB notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

Starting from MySQL 3.23.40b, InnoDB uses a novel file flush technique called doublewrite. It

adds safety to crash recovery after an operating system crash or a power outage, and improves performance on most Unix flavors by reducing the need for `fsync()` operations.

Doublewrite means that before writing pages to a data file, InnoDB first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does InnoDB write the pages to their proper positions in the data file. If the operating system crashes in the middle of a page write, InnoDB can later find a good copy of the page from the doublewrite buffer during recovery.

15.15.2. Using Raw Devices for the Tablespace

Starting from MySQL 3.23.41, you can use raw disk partitions as tablespace data files. By using a raw disk, you can perform non-buffered I/O on Windows and on some Unix systems without filesystem overhead, which might improve performance.

When you create a new data file, you must put the keyword `newraw` immediately after the data file size in `innodb_data_file_path`. The partition must be at least as large as the size that you specify. Note that 1MB in InnoDB is $1024 * 1024$ bytes, whereas 1MB usually means 1,000,000 bytes in disk specifications.

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Gnewraw:/dev/hdd2:2Gnewraw
```

The next time you start the server, InnoDB notices the `newraw` keyword and initializes the new partition. However, do not create or change any InnoDB tables yet. Otherwise, when you next restart the server, InnoDB reinitializes the partition and your changes are lost. (Starting from 3.23.44, as a safety measure InnoDB prevents users from modifying data when any partition with `newraw` is specified.)

After InnoDB has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:5Graw:/dev/hdd2:2Graw
```

Then restart the server and InnoDB allows changes to be made.

On Windows, starting from 4.1.1, you can allocate a disk partition as a data file like this:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D:10Gnewraw
```

The `//./` corresponds to the Windows syntax of `\\.\` for accessing physical drives.

When you use raw disk partitions, be sure that they have permissions that allow read and write access by the account used for running the MySQL server.

15.15.3. File Space Management

The data files you define in the configuration file form the tablespace of InnoDB. The files are simply concatenated to form the tablespace. There is no striping in use. Currently you cannot define where in the tablespace your tables are allocated. However, in a newly created tablespace, InnoDB allocates space starting from the first data file.

The tablespace consists of database pages with a default size of 16KB. The pages are grouped into extents of 64 consecutive pages. The "files" inside a tablespace are called segments in InnoDB. The name of the "rollback segment" is somewhat confusing because it actually contains many segments in the tablespace.

Two segments are allocated for each index in InnoDB. One is for non-leaf nodes of the B-tree, the other is for the leaf nodes. The idea here is to achieve better sequentiality for the leaf nodes, which contain the data.

When a segment grows inside the tablespace, InnoDB allocates the first 32 pages to it individually. After that InnoDB starts to allocate whole extents to the segment. InnoDB can add to a large segment up to 4 extents at a time to ensure good sequentiality of data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an InnoDB tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS`, InnoDB reports the extents that are definitely free in the tablespace. InnoDB always reserves some extents for clean-up and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, InnoDB contracts the corresponding B-tree indexes. It depends on the pattern of deletes whether that frees individual pages or extents to the tablespace, so that the freed space becomes available for other users. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only in an (automatic) purge operation after they are no longer needed for transaction rollbacks or consistent reads.

15.15.4. Defragmenting a Table

If there are random insertions into or deletions from the indexes of a table, the indexes may become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

A symptom of fragmentation is that a table takes more space than it 'should take'. How much exactly is that, is difficult to determine. All InnoDB data and indexes are stored in B-trees, and their fill-factor may vary 50 % to 100 %. Another symptom of fragmentation is that a table scan:

```
SELECT COUNT(*) FROM t WHERE a_non_indexed_column <> 12345;
```

takes more time than 'it should take'. (Above we are fooling the SQL optimizer to scan the clustered index, not a secondary index.) Most disks can read 10 - 50 MB/s. That can be used to estimate how fast a table scan should run.

It can speed up index scans if you periodically perform a ``null" `ALTER TABLE` operation:

```
ALTER TABLE tbl_name TYPE=InnoDB
```

That causes MySQL to rebuild the table. Another way to perform a defragmentation operation is to use **mysqldump** to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions to an index are always ascending and records are deleted only from the end, the InnoDB file space management algorithm guarantees that fragmentation in the index does not occur.

15.16. Error Handling

Error handling in InnoDB is not always the same as specified in the SQL standard. According to the standard, any error during an SQL statement should cause the rollback of that statement. InnoDB sometimes rolls back only part of the statement, or the whole transaction. The following items describe how InnoDB performs error handling:

- If you run out of file space in the tablespace, you get the MySQL `Table is full` error and InnoDB rolls back the SQL statement.

- A transaction deadlock or a timeout in a lock wait causes InnoDB to roll back the whole transaction.
- A duplicate-key error rolls back the SQL statement, if you have not specified the IGNORE option in your statement.
- A "row too long" error rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the InnoDB storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During such implicit rollbacks, as well as during the explicit `ROLLBACK SQL` command, `SHOW PROCESSLIST` displays "Rolling back" in the `State` column for the connection (starting from MySQL 4.1.8).

15.16.1. InnoDB Error Codes

The following is a non-exhaustive list of common InnoDB-specific errors that you may encounter, with information about why they occur and how to resolve the problem.

- 1005 (ER_CANT_CREATE_TABLE)
Cannot create table. If the error message string refers to `errno 150`, table creation failed because a foreign key constraint was not correctly formed.
- 1016 (ER_CANT_OPEN_FILE)
Cannot find the InnoDB table from the InnoDB data files though the `.frm` file for the table exists. See Section 15.18.1, "Troubleshooting InnoDB Data Dictionary Operations".
- 1114 (ER_RECORD_FILE_FULL)
InnoDB has run out of free space in the tablespace. You should reconfigure the tablespace to add a new data file.
- 1205 (ER_LOCK_WAIT_TIMEOUT)
Lock wait timeout expired. Transaction was rolled back.
- 1213 (ER_LOCK_DEADLOCK)
Transaction deadlock. You should rerun the transaction.
- 1216 (ER_NO_REFERENCED_ROW)
You are trying to add a row but there is no parent row, and a foreign key constraint fails. You should add the parent row first.
- 1217 (ER_ROW_IS_REFERENCED)
You are trying to delete a parent row that has children, and a foreign key constraint fails. You should delete the children first.

15.16.2. Operating System Error Codes

To print the meaning of an operating system error number, use the `perror` program that comes with the MySQL distribution.

The following table provides a list of some common Linux system error codes. For a more complete

list, see Linux source code [<http://www.iglu.org.il/lxr/source/include/asm-i386/errno.h>].

- 1 (EPERM)
Operation not permitted
- 2 (ENOENT)
No such file or directory
- 3 (ESRCH)
No such process
- 4 (EINTR)
Interrupted system call
- 5 (EIO)
I/O error
- 6 (ENXIO)
No such device or address
- 7 (E2BIG)
Arg list too long
- 8 (ENOEXEC)
Exec format error
- 9 (EBADF)
Bad file number
- 10 (ECHILD)
No child processes
- 11 (EAGAIN)
Try again
- 12 (ENOMEM)
Out of memory
- 13 (EACCES)
Permission denied
- 14 (EFAULT)
Bad address
- 15 (ENOTBLK)
Block device required
- 16 (EBUSY)

- Device or resource busy
 - 17 (EEXIST)
File exists
 - 18 (EXDEV)
Cross-device link
 - 19 (ENODEV)
No such device
 - 20 (ENOTDIR)
Not a directory
 - 21 (EISDIR)
Is a directory
 - 22 (EINVAL)
Invalid argument
 - 23 (ENFILE)
File table overflow
 - 24 (EMFILE)
Too many open files
 - 25 (ENOTTY)
Inappropriate ioctl for device
 - 26 (ETXTBSY)
Text file busy
 - 27 (EFBIG)
File too large
 - 28 (ENOSPC)
No space left on device
 - 29 (ESPIPE)
Illegal seek
 - 30 (EROFS)
Read-only file system
 - 31 (EMLINK)
Too many links

The following table provides a list of some common Windows system error codes. For a complete

list see the Microsoft website
[http://msdn.microsoft.com/library/default.asp?url=/library/en-us/debug/base/system_error_codes.asp].

- 1 (ERROR_INVALID_FUNCTION)
Incorrect function.
- 2 (ERROR_FILE_NOT_FOUND)
The system cannot find the file specified.
- 3 (ERROR_PATH_NOT_FOUND)
The system cannot find the path specified.
- 4 (ERROR_TOO_MANY_OPEN_FILES)
The system cannot open the file.
- 5 (ERROR_ACCESS_DENIED)
Access is denied.
- 6 (ERROR_INVALID_HANDLE)
The handle is invalid.
- 7 (ERROR_ARENA_TRASHED)
The storage control blocks were destroyed.
- 8 (ERROR_NOT_ENOUGH_MEMORY)
Not enough storage is available to process this command.
- 9 (ERROR_INVALID_BLOCK)
The storage control block address is invalid.
- 10 (ERROR_BAD_ENVIRONMENT)
The environment is incorrect.
- 11 (ERROR_BAD_FORMAT)
An attempt was made to load a program with an incorrect format.
- 12 (ERROR_INVALID_ACCESS)
The access code is invalid.
- 13 (ERROR_INVALID_DATA)
The data is invalid.
- 14 (ERROR_OUTOFMEMORY)
Not enough storage is available to complete this operation.
- 15 (ERROR_INVALID_DRIVE)
The system cannot find the drive specified.

- 16 (ERROR_CURRENT_DIRECTORY)
The directory cannot be removed.
- 17 (ERROR_NOT_SAME_DEVICE)
The system cannot move the file to a different disk drive.
- 18 (ERROR_NO_MORE_FILES)
There are no more files.
- 19 (ERROR_WRITE_PROTECT)
The media is write protected.
- 20 (ERROR_BAD_UNIT)
The system cannot find the device specified.
- 21 (ERROR_NOT_READY)
The device is not ready.
- 22 (ERROR_BAD_COMMAND)
The device does not recognize the command.
- 23 (ERROR_CRC)
Data error (cyclic redundancy check).
- 24 (ERROR_BAD_LENGTH)
The program issued a command but the command length is incorrect.
- 25 (ERROR_SEEK)
The drive cannot locate a specific area or track on the disk.
- 26 (ERROR_NOT_DOS_DISK)
The specified disk or diskette cannot be accessed.
- 27 (ERROR_SECTOR_NOT_FOUND)
The drive cannot find the sector requested.
- 28 (ERROR_OUT_OF_PAPER)
The printer is out of paper.
- 29 (ERROR_WRITE_FAULT)
The system cannot write to the specified device.
- 30 (ERROR_READ_FAULT)
The system cannot read from the specified device.
- 31 (ERROR_GEN_FAILURE)
A device attached to the system is not functioning.
- 32 (ERROR_SHARING_VIOLATION)

The process cannot access the file because it is being used by another process.

- 33 (ERROR_LOCK_VIOLATION)

The process cannot access the file because another process has locked a portion of the file.

- 34 (ERROR_WRONG_DISK)

The wrong diskette is in the drive. Insert %2 (Volume Serial Number: %3) into drive %1.

- 36 (ERROR_SHARING_BUFFER_EXCEEDED)

Too many files opened for sharing.

- 38 (ERROR_HANDLE_EOF)

Reached the end of the file.

- 39 (ERROR_HANDLE_DISK_FULL)

The disk is full.

- 87 (ERROR_INVALID_PARAMETER)

The parameter is incorrect. (If you get this error in MySQL-4.1.9 on Windows, and you have set `innodb_file_per_table` in `my.cnf` or `my.ini`, then this is Bug #8021 [<http://bugs.mysql.com/8021>], and a workaround is to put the line `innodb_flush_method=unbuffered` to your `my.cnf` or `my.ini`.)

- 112 (ERROR_DISK_FULL)

The disk is full.

- 123 (ERROR_INVALID_NAME)

The filename, directory name, or volume label syntax is incorrect.

- 1450 (ERROR_NO_SYSTEM_RESOURCES)

Insufficient system resources exist to complete the requested service.

15.17. Restrictions on InnoDB Tables

- A table cannot contain more than 1000 columns.
- The internal maximum key length is 3500 bytes, but MySQL itself restricts this to 1024 bytes.
- The maximum row length, except for BLOB and TEXT columns, is slightly less than half of a database page. That is, the maximum row length is about 8000 bytes. LONGBLOB and LONGTEXT columns must be less than 4GB, and the total row length, including also BLOB and TEXT columns, must be less than 4GB. InnoDB stores the first 512 bytes of a BLOB or TEXT column in the row, and the rest into separate pages.
- On some old operating systems, data files must be less than 2GB.
- The combined size of the InnoDB log files must be less than 4GB.
- The minimum tablespace size is 10MB. The maximum tablespace size is four billion database pages (64TB). This is also the maximum size for a table.

- InnoDB tables do not support FULLTEXT indexes.
- InnoDB tables do not support spatial column types.
- ANALYZE TABLE counts cardinality by doing 10 random dives to each of the index trees and updating index cardinality estimates accordingly. Note that because these are only estimates, repeated runs of ANALYZE TABLE may produce different numbers. This makes ANALYZE TABLE fast on InnoDB tables but not 100% accurate as it doesn't take all rows into account.

MySQL uses index cardinality estimates only in join optimization. If some join is not optimized in the right way, you may try using ANALYZE TABLE. In the few cases that ANALYZE TABLE doesn't produce values good enough for your particular tables, you can use FORCE INDEX with your queries to force the usage of a particular index, or set max_seeks_for_key to ensure that MySQL prefers index lookups over table scans. See Section 5.3.3, “Server System Variables”. See Section A.6, “Optimizer-Related Issues”.

- On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in binary format from Unix to Windows or from Windows to Unix, you should have all database and table names in lowercase.
- **Warning:** Do *not* convert MySQL system tables in the mysql database from MyISAM to InnoDB tables! This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or re-generate them with the **mysql_install_db** script.
- InnoDB does not keep an internal count of rows in a table. (This would actually be somewhat complicated because of multi-versioning.) To process a SELECT COUNT(*) FROM T statement, InnoDB must scan an index of the table, which takes some time if the index is not entirely in the buffer pool. To get a fast count, you have to use a counter table you create yourself and let your application update it according to the inserts and deletes it does. If your table does not change often, using the MySQL query cache is a good solution. SHOW TABLE STATUS also can be used if an approximate row count is sufficient. See Section 15.12, “InnoDB Performance Tuning Tips”.
- For an AUTO_INCREMENT column, you must always define an index for the table, and that index must contain just the AUTO_INCREMENT column. In MyISAM tables, the AUTO_INCREMENT column may be part of a multi-column index.
- InnoDB does not support the AUTO_INCREMENT table option for setting the initial sequence value in a CREATE TABLE or ALTER TABLE statement. To set the value with InnoDB, insert a dummy row with a value one less and delete that dummy row, or insert the first row with an explicit value specified.
- When you restart the MySQL server, InnoDB may reuse an old value for an AUTO_INCREMENT column (that is, a value that was assigned to an old transaction that was rolled back).
- When an AUTO_INCREMENT column runs out of values, InnoDB wraps a BIGINT to -9223372036854775808 and BIGINT UNSIGNED to 1. However, BIGINT values have 64 bits, so do note that if you were to insert one million rows per second, it would still take nearly three hundred thousand years before BIGINT reached its upper bound. With all other integer type columns, a duplicate-key error results. This is similar to how MyISAM works, because it is mostly general MySQL behavior and not about any storage engine in particular.
- DELETE FROM tbl_name does not regenerate the table but instead deletes all rows, one by one.
- TRUNCATE tbl_name is mapped to DELETE FROM tbl_name for InnoDB and doesn't reset the AUTO_INCREMENT counter.
- SHOW TABLE STATUS does not give accurate statistics on InnoDB tables, except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.

- Before MySQL 4.0.14 or 4.1.0, if you tried to create a unique index on a prefix of a column you got an error:

```
CREATE TABLE T (A CHAR(20), B INT, UNIQUE (A(5))) TYPE = InnoDB;
```

If you created a non-unique index on a prefix of a column, InnoDB created an index over the whole column. These restrictions were removed in MySQL 4.0.14.

- Before MySQL 4.0.20 or 4.1.2, the MySQL `LOCK TABLES` operation does not know about InnoDB row-level locks set by completed SQL statements. This means that you can get a table lock on a table even if there still exist transactions by other users who have row level locks on the same table. Thus your operations on the table may have to wait if they collide with these locks of other users. Also a deadlock is possible. However, this does not endanger transaction integrity, because the row level locks set by InnoDB always take care of the integrity. Also, a table lock prevents other transactions from acquiring more row level locks (in a conflicting lock mode) on the table.
- Beginning with MySQL 4.0.20 and 4.1.2, the MySQL `LOCK TABLES` operation acquires two locks on each table if `innodb_table_locks=1`. (1 is the default.) In addition to a table lock on the MySQL layer, it also acquires an InnoDB table lock. Older versions of MySQL do not acquire InnoDB table locks. Beginning with MySQL 4.0.22 and 4.1.7, the old behavior can be selected by setting `innodb_table_locks=0`. If no InnoDB table lock is acquired, `LOCK TABLES` completes even if some records of the tables are being locked by other transactions.
- All InnoDB locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke `LOCK TABLES` on InnoDB tables in `AUTO-COMMIT=1` mode, because the acquired InnoDB table locks would be released immediately.
- Sometimes it would be useful to lock further tables in the course of a transaction. Unfortunately, `LOCK TABLES` in MySQL performs an implicit `COMMIT` and `UNLOCK TABLES`. An InnoDB variant of `LOCK TABLES` has been planned that can be executed in the middle of a transaction.
- Before MySQL 3.23.52, replication always ran with autocommit enabled. Therefore consistent reads in the slave would also see partially processed transactions, and thus the read would not be really consistent in the slave. This restriction was removed in MySQL 3.23.52.
- The `LOAD TABLE FROM MASTER` statement for setting up replication slave servers does not yet work for InnoDB tables. A workaround is to alter the table to MyISAM on the master, do then the load, and after that alter the master table back to InnoDB.
- The default database page size in InnoDB is 16KB. By recompiling the code, you can set it to values ranging from 8KB to 64KB. You have to update the values of `UNIV_PAGE_SIZE` and `UNIV_PAGE_SIZE_SHIFT` in the `univ.i` source file.

15.18. InnoDB Troubleshooting

- A general rule is that when an operation fails or you suspect a bug, you should look at the MySQL server error log, which typically has a name something like `hostname.err`, or possibly `mysql.err` on Windows.
- When doing troubleshooting, it is usually best to run the MySQL server from the command prompt, not through the `mysqld_safe` wrapper or as a Windows service. You then see what **mysqld** prints to the command prompt window, and you have a better grasp of what is going on. On Windows, you must start the server with the `--console` option to direct the output to the console window.
- Use the InnoDB Monitors to obtain information about a problem. If the problem is performance-related, or your server appears to be hung, you should use `innodb_monitor` to print information about the internal state of InnoDB. If the problem is with locks, use `in-`

`nodb_lock_monitor`. If the problem is in creation of tables or other data dictionary operations, use `innodb_table_monitor` to print the contents of the InnoDB internal data dictionary.

- If you suspect a table is corrupt, run `CHECK TABLE` on that table.

15.18.1. Troubleshooting InnoDB Data Dictionary Operations

A specific issue with tables is that the MySQL server keeps data dictionary information in `.frm` files it stores in the database directories, while InnoDB also stores the information into its own data dictionary inside the tablespace files. If you move `.frm` files around, or use `DROP DATABASE` in MySQL versions before 3.23.44, or the server crashes in the middle of a data dictionary operation, the `.frm` files may end up out of sync with the InnoDB internal data dictionary.

A symptom of an out-of-sync data dictionary is that a `CREATE TABLE` statement fails. If this occurs, you should look in the server's error log. If the log says that the table already exists inside the InnoDB internal data dictionary, you have an orphaned table inside the InnoDB tablespace files that has no corresponding `.frm` file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphaned table by following the instructions given in the error message.

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open a `.InnoDB` file:

```
ERROR 1016: Can't open file: 'child2.InnoDB'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphaned `.frm` file without a corresponding table inside InnoDB. You can drop the orphaned `.frm` file by deleting it manually.

If MySQL crashes in the middle of an `ALTER TABLE` operation, you may end up with an orphaned temporary table inside the InnoDB tablespace. With `innodb_table_monitor` you see a table whose name is `#sql-...` Starting from MySQL 4.0.6, you can perform SQL statements also on tables whose name contains the character '#' if you enclose the name in backticks. Thus, you can drop such an orphaned table like any other orphaned table with the method described above. Note that to copy or rename a file in the Unix shell, you need to put the file name in double quotes if the file name contains '#'

Older MySQL versions did not allow accessing any table with a name containing '#'. The solution in older MySQL versions is to use a special InnoDB mechanism available starting from MySQL 3.23.48. When you have an orphaned table `#sql-id` inside the tablespace, you can cause InnoDB to rename it to `rsql-id_recover_innodb_tmp_table` with the following statement:

```
CREATE TABLE `rsql-id_recover_innodb_tmp_table`(...) TYPE=InnoDB;
```

Chapter 16. MySQL Cluster

MySQL Cluster is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. It uses the **NDB Cluster** storage engine to enable running several MySQL servers in a cluster. This storage engine is available and in binary releases from MySQL-Max 4.1.3. Beginning with MySQL 4.1.10a, it is also available in RPMs compatible with most modern Linux distributions. (Note that both the `mysql-server` and `mysql-max` RPMs must be installed in order to have MySQL Cluster capability.)

The operating systems on which MySQL Cluster is currently available are Linux, Mac OS X, and Solaris. We are working to make Cluster run on all operating systems supported by MySQL, including Windows.

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL AB Web site at <http://www.mysql.com/products/cluster/>.

You may wish to make use of two additional online resources provided by MySQL AB:

- the MySQL Cluster <http://lists.mysql.com/cluster> [mailing list].
- the Cluster topic area [<http://forums.mysql.com/list.php?25>] on the MySQL User Forums.

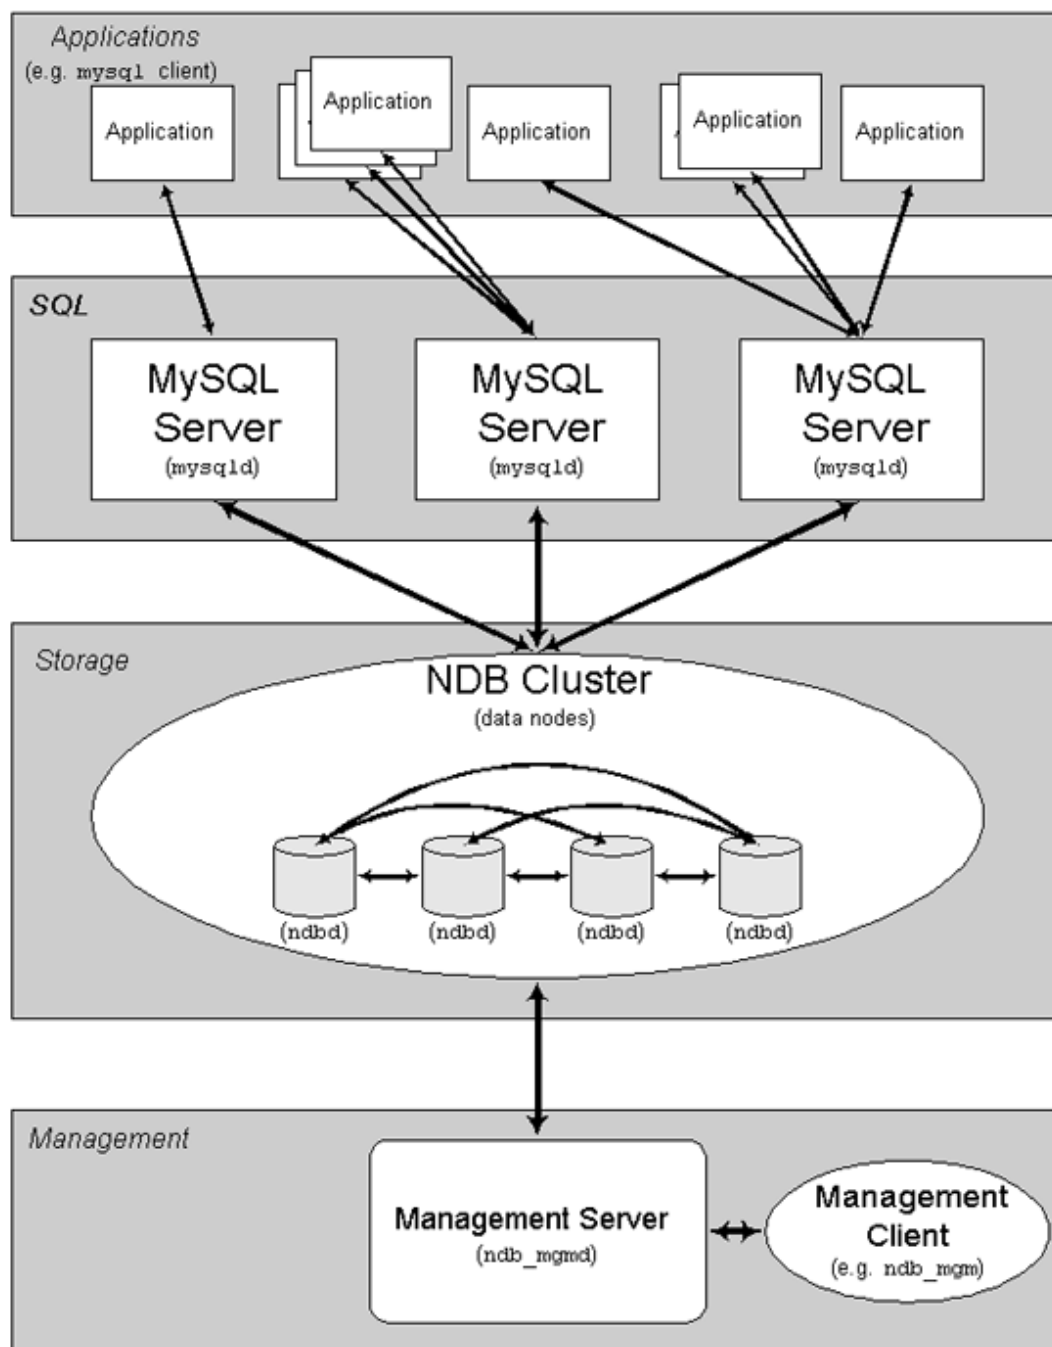

Answers to some commonly asked questions about Cluster may be found in the Section 16.10, “MySQL Cluster FAQ”. If you are new to MySQL Cluster, you may also find our Developer Zone article [How to set up a MySQL Cluster for two servers](http://dev.mysql.com/tech-resources/articles/mysql-cluster-for-two-servers.html) [<http://dev.mysql.com/tech-resources/articles/mysql-cluster-for-two-servers.html>] to be helpful.

16.1. MySQL Cluster Overview

MySQL Cluster is a technology which enables clustering of in-memory databases in a share-nothing system. The share-nothing architecture allows the system to work with very inexpensive hardware, and without any specific requirements on hardware or software. It also does not have any single point of failure because each component has its own memory and disk.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called **NDB**. In our documentation, the term **NDB** refers to the part of the setup that is specific to the storage engine, whereas **MySQL Cluster** refers to the combination of MySQL and the new storage engine.

A MySQL Cluster consists of a set of computers, each running a number of processes including MySQL servers, data nodes for NDB Cluster, management servers, and (possibly) specialized data access programs. The relationship of these components in a cluster is shown here:

All these programs work together to form a MySQL Cluster. When data is stored in the NDB Cluster storage engine, the tables are stored in the data nodes. Such tables are directly accessible from all other MySQL servers in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Since transactional applications are expected to handle transaction failure, this should not be a source of problems.

By bringing MySQL Cluster to the Open Source world, MySQL makes clustered data management with high availability, high performance, and scalability available to all who need it.

16.2. Basic MySQL Cluster Concepts

NDB is an in-memory storage engine offering high-availability and data-persistence features.

The NDB storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster's NDB storage engine contains a complete set of data, dependent only on other data within the cluster itself.

We will now describe how to set up a MySQL Cluster consisting of an NDB storage engine and some MySQL servers.

The cluster portion of MySQL Cluster is currently configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a **node**.

Note: In many contexts, the term "node" is used to indicate a computer, but when discussing MySQL Cluster it means a *process*. There can be any number of nodes on a single computer, for which we use the term **cluster host**.

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- The **management (MGM) node**: The role of this type of node is to manage the other nodes within the MySQL Cluster, such as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. A MGM node is started with the command **ndb_mgmd**.
- The **data node**: This is the type of node that stores the cluster's data. There are as many data nodes as there are replicas, times the number of fragments. For example, with two replicas, each having two fragments, you will need four data nodes. It is not necessary to have more than one replica. A data node is started with the command **ndbd**.
- The **SQL node**: This is the node that accesses the cluster data. In the case of MySQL Cluster, a client node is a traditional MySQL server that uses the NDB Cluster storage engine. An SQL node is typically started with the command **mysqld --ndbcluster** or simply by using **mysqld** with `ndbcluster` added to `my.cnf`.

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that storage nodes are homogenous in terms of processor power, memory space, and bandwidth. In addition, in order to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server (MGM node) manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These are of two types:

- **Standard MySQL clients**: These are no different for MySQL Cluster than they are for standard (non-Cluster) MySQL. In other words, MySQL Cluster can be accessed from existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on.
- **Management clients**: These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on.

16.3. Simple Multi-Computer How-To

This section is a "How-To" in which we will describe the basics for how to plan, install, configure, and run a viable MySQL Cluster. Unlike the example in Section 16.4, "MySQL Cluster Configuration", the result of following the guidelines and procedures outlined below should be a usable MySQL Cluster which meets minimum requirements for availability and safeguarding of data.

In this section, we will cover: hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

Basic Assumptions

This How-To makes the following assumptions:

1. We are setting up our cluster with 4 nodes, each on a separate host, and each with a fixed network address on a typical Ethernet as shown here:

Node	IP Address
Management (MGM) node	192.168.0.10
MySQL server (SQL) node	192.168.0.20
Storage (NDBD) node "A"	192.168.0.30
data node "B"	192.168.0.40

This may be made clearer in the following diagram:

Note: In the interest of simplicity (and reliability), we will use only numeric IP addresses in this How-To. However, if DNS resolution is available on your network, then it is possible to use hostnames in lieu of IP addresses in configuring Cluster. Alternatively, you can also use the `/etc/hosts` file or your operating system's equivalent for providing a means to do host

lookup if such is available.

- Each host is an Intel-based desktop PC running a common, generic Linux distribution installed to disk in a standard configuration, and with no unnecessary services. The core OS with a standard TCP/IP networking client should be sufficient. Also for the sake of simplicity, we also assume that the filesystems on all hosts are set up identically. In the event that they are not, you will need to adapt these instructions that follow accordingly.
- Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all 4 hosts are connected via a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput; that is, all 4 machines in the cluster should have 100 Mbps cards *or* all 4 machines should have 1 Gbps cards.) MySQL Cluster will work in a 100 Mbps network; however, using gigabit Ethernet will provide better performance.

Note that MySQL Cluster is not intended for use in a network whose connectivity is less than 100 Mbps. For this reason (among others), attempting to run a MySQL Cluster over a public network such as the Internet is not likely to be successful, and is not recommended.

- For our sample data, we will use the **world** database which is available for download from the MySQL AB website. As this database takes up a relatively small amount of space, we assume that each machine has 256 MB RAM, which should be sufficient for running the operating system and host NDB process, and (for the data nodes) for storing the database.

While we refer to a Linux operating system in this How-To, the instructions and procedures that we provide here should be easily adaptable to either Solaris or Mac OS X. We also assume that you already know how to perform a minimal installation and configuration of the operating system with networking capability, or that you are able to obtain assistance in this elsewhere if needed.

We discuss MySQL Cluster hardware, software, and networking requirements in somewhat greater detail in the next section. (See Section 16.3.1, “Hardware, Software, and Networking”.)

16.3.1. Hardware, Software, and Networking

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (Note that this is subject to change, and that we intend to implement disk-based storage in a future MySQL Cluster release.) Naturally, multiple and faster CPUs will enhance performance. Memory requirements for Cluster processes are relatively small.

The software requirements for Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For Mac OS X or Solaris, the standard installation is sufficient. For Linux, a standard, “out of the box” installation should be all that is necessary. The MySQL software requirements are simple: all that is needed is a production release of MySQL-max 4.1.3 or newer; you must use the `-max` version of MySQL in order to have Cluster support. It is not necessary to compile MySQL yourself merely to be able to use Cluster. In this How-To, we will assume that you are using the `-max` binary appropriate to your operating system, available via the MySQL software downloads page at <http://dev.mysql.com/downloads>.

For inter-node communication, Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with non-Cluster machines for the following reasons:

- Security:** Communications between Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarised Zone (DMZ)

[http://compnetworking.about.com/cs/networksecurity/g/bldef_dmz.htm] or elsewhere.

- **Efficiency:** Setting up a Cluster on a private or protected network allows for the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorised access to Cluster data, it also ensures that Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See Section 16.7, “Using High-Speed Interconnects with MySQL Cluster” for more about this protocol and its use with MySQL Cluster.

16.3.2. Installation

Each MySQL Cluster host computer running storage or SQL nodes must have installed on it a MySQL-max binary. For management nodes, it is not necessary to install the MySQL server binary, but you do have to install the MGM server daemon and client binaries (**ndb_mgmd** and **ndb_mgm**, respectively). In this section, we will cover the steps necessary to install the correct binaries for each type of Cluster node.

As of this writing, the most recent production version for Linux was MySQL 4.1.10a; if a more recent version is available, you should use that instead, and substitute the version number in the following instructions as appropriate. MySQL AB provides precompiled binaries, and there is generally no need to compile these yourself. (If you do require a custom binary, see Section 2.8.3, “Installing from the Development Source Tree”.) Therefore, the first step in the installation process for each cluster host is to download the file `mysql-max-4.1.10a-pc-linux-gnu-i686.tar.gz` from the MySQL downloads area [<http://dev.mysql.com/downloads>], and we will assume that you have placed it in each machine's `/var/tmp` directory.

RPMs are also available for both 32-bit and 64-bit Linux platforms; as of MySQL 4.1.10a, the `-max` binaries installed by the RPMs supports the NDBCluster storage engine. If you choose to use these rather than the binary files, be aware that you must install **both** the `-server` and `-max` packages on all machines that are to host cluster nodes. (See Linux for more information about installing MySQL using the RPMs.) After installing from RPM, you will still need to configure the cluster as discussed in Section 16.3.3, “Configuration”.

Note: After completing the installation, do not yet start any of the binaries. We will show you how to do so following the configuration of all nodes.

Storage and SQL Node Installation

On each of the 3 machines designated to host storage or SQL nodes, perform the following steps as the system root user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether or not there are already a `mysql` group and `mysql` user on the system, as some OS distributions create these as part of the operating system installation process. If these are not already present, then create a new `mysql` user group, then add a `mysql` user to this group:

```
groupadd mysql
useradd -g mysql mysql
```

2. Change to the directory containing the downloaded file; unpack the archive; create a symlink to the `mysql-max` executable:

```
cd /var/tmp
```

```
tar -xzvf -C /usr/local/bin mysql-max-4.1.10a-pc-linux-gnu-i686.tar.gz
ln -s /usr/local/bin/mysql-max-4.1.10a-pc-linux-gnu-i686 mysql
```

3. Change to the `mysql` directory, and run the supplied script for creating the system databases:

```
cd mysql
scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
chown -R root .
chown -R mysql data
chgrp -R mysql .
```

Note that the data directory on each machine hosting a data node is `/usr/local/mysql/data`. We will make use of this piece of information when we configure the management node. (See Section 16.3.3, “Configuration”.)

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
cp support-files/mysql.server /etc/rc.d/init.d/
chmod +x /etc/rc.d/init.d/mysql.server
chkconfig --add mysql.server
```

Here we use Red Hat's **chkconfig** for creating links to the startup scripts; use whatever means is appropriate for this purpose on your operating system/distribution, such as **update-rc.d** on Debian.

Remember that the steps listed above must be performed separately for each machine on which a storage or SQL node is to reside.

Management Node Installation

For the MGM (management) node, it is not necessary to install the **mysqld** executable, only the binaries for the MGM server and client, which can be found in the downloaded `-max` archive. Again we assume that you have placed this file in `/var/tmp`. As root (that is, after using **su root** or your system's equivalent for temporarily assuming the system root account's privileges), perform the following steps to install **ndb_mgm** and **ndb_mgmd** on the Cluster management node host:

1. Move to the `/var/tmp` directory, and extract the **ndb_mgm** and **ndb_mgmd** from the archive into a suitable directory such as `/usr/local/bin`:

```
cd /var/tmp
tar -zxvf mysql-max-4.1.10a-pc-linux-gnu-i686.tar.gz /usr/local/bin */bin
```

2. Move to the directory into which you unpacked the files, and then make both of these executable:

```
cd /usr/local/bin
chmod +x ndb_mgm*
```

In Section 16.3.3, “Configuration”, we will create and write configuration files for all of the nodes in our example Cluster.

16.3.3. Configuration

For our 4-node, 4-host MySQL Cluster, we will need to write 4 configuration files, 1 per node/host.

- Each data node or SQL node will require a `my.cnf` file that provides two pieces of information: a **connectstring** telling the node where to find the MGM node, and a line telling the MySQL server on this host (the machine hosting the data node) to run in NDB mode.

For more information on connectstrings, see Section 16.4.4.2, “The MySQL Cluster connect-string”.

- The management node will need a `config.ini` file telling it how many replicas are to be maintained, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where data will be saved to disk on each data node, and where to find any SQL nodes.

Configuring the Storage and SQL Nodes

The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited (and created if necessary) using any text editor, for example:

```
vi /etc/my.cnf
```

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[MYSQLD]                # Options for mysqld process:
ndbcluster              # run NDB engine
ndb-connectstring=192.168.0.10 # location of MGM node

[MYSQL_CLUSTER]        # Options for ndbd process:
ndb-connectstring=192.168.0.10 # location of MGM node
```

After entering the above, save this file and exit the text editor. Do this for the machines hosting data node "A", data node "B", and the SQL node.

Configuring the Management Node

The first step in configuring the MGM node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as root):

```
mkdir /var/lib/mysql-cluster
cd /var/lib/mysql-cluster
vi config.ini
```

We show `vi` being used here to create the file, but any text editor should work just as well.

For our representative setup, the `config.ini` file should read as follows:

```
[NDBD DEFAULT]        # Options affecting ndbd processes on all data nodes:
NoOfReplicas=2        # Number of replicas
DataMemory=80M        # How much memory to allocate for data storage
IndexMemory=52M       # How much memory to allocate for index storage
                      # For DataMemory and IndexMemory, we have used the
                      # default values. Since the "world" database takes up
                      # only about 500KB, this should be more than enough for
                      # this example Cluster setup.

[TCP DEFAULT]         # TCP/IP options:
portnumber=2202       # This the default; however, you can use any
```

```

# port that is free for all the hosts in cluster
# Note: It is recommended beginning with MySQL 5.0 that
# you do not specify the portnumber at all and simply allow
# the default value to be used instead

[NDB_MGMD]                # Management process options:
hostname=192.168.0.10     # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster # Directory for MGM node logfiles

[NDBD]                    # Options for data node "A":
                           # (one [NDBD] section per data node)
hostname=192.168.0.30     # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's datafiles

[NDBD]                    # Options for data node "B":
                           # (one [NDBD] section per data node)
hostname=192.168.0.40     # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for this data node's datafiles

[MYSQLD]                  # SQL node options:
hostname=192.168.0.20     # Hostname or IP address
datadir=/usr/local/mysql/data # Directory for SQL node's datafiles
                           # (additional mysqld connections can be
                           # specified for this node for various
                           # purposes such as running ndb_restore)

```

(NOTE: The "world" database can be downloaded from <http://dev.mysql.com/doc/> where it can be found listed under "Examples".)

Once all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 16.3.4, "Initial Startup".

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see Section 16.4.4, "Configuration File" and Section 16.4, "MySQL Cluster Configuration". For configuration of MySQL Cluster as relates to making backups, see Section 16.6.4.4, "Configuration for Cluster Backup".

Note: The default port for Cluster management nodes is 1186; the default port for data nodes is 2202.

16.3.4. Initial Startup

Starting the cluster is not very difficult once it has been configured. Each cluster node process must be started separately, and on the host where it resides. While it is possible to start the nodes in any order, it is recommended that the management node be started first, followed by the storage nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the MGM node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

Note that **ndb_mgmd** must be told where to find its configuration file, using the `-f` or `-config-file` option. (See Section 16.5.3, "**ndb_mgmd**, the Management Server Process" for details.)

2. On each of the data node hosts, run this command to start the NDBD process for the first time:

```
shell> ndbd --initial
```

Note that it is very important to use the `--initial` parameter **only** when starting `ndbd` for the first time, or when restarting after backup/restore or configuration change. This is because this parameter will cause the node to delete any files created by earlier `ndbd` instances needed for recovery, including the recovery log files.

3. On the cluster host where the SQL node is to reside, execute a normal `mysqld` startup command as shown here:

```
shell> mysqld &
```

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client; the output should look like what is shown below:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> show
Connected to Management Server at: localhost:1186
Cluster Configuration
-----
[ndbd(NDB)]      2 node(s)
id=2      @192.168.0.30 (Version: 4.1.11, Nodegroup: 0, Master)
id=3      @192.168.0.40 (Version: 4.1.11, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=1      @192.168.0.10 (Version: 4.1.11)

[mysqld(SQL)]   1 node(s)
id=4      (Version: 4.1.11)
```

You may see some slight differences depending upon the exact version of MySQL that you are using.

Note: If you are using an older version of MySQL, you may see the SQL node referenced as `'[mysqld(API)]'`. This reflects an older usage which is now deprecated.

You should now be ready to work with databases, tables, and data in MySQL Cluster. See Section 16.3.5, “Loading Sample Data and Performing Queries” for a brief discussion.

16.3.5. Loading Sample Data and Performing Queries

Working with data in MySQL Cluster is not much different than working with it MySQL without Cluster. There are two points to keep in mind when doing so:

- Tables must be created with the `ENGINE=NDB` or `ENGINE=NDBCLUSTER` option, or be altered (using `ALTER TABLE`) to use the `NDB CLUSTER` storage engine in order to have them replicated in the cluster. If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script(s) in a text editor and add this option to any table creation statements, or replace any existing `ENGINE` (or `TYPE`) option(s) with one of these. For example, suppose that you have the sample `world` database on another MySQL server (that doesn't support MySQL Cluster), and you wish to export the definition for the `CITY` table:

```
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```
DROP TABLE IF EXISTS City;
CREATE TABLE City (
```

```

ID int(11) NOT NULL auto_increment,
Name char(35) NOT NULL default '',
CountryCode char(3) NOT NULL default '',
District char(20) NOT NULL default '',
Population int(11) NOT NULL default '0',
PRIMARY KEY (ID)
) TYPE=MyISAM;

INSERT INTO City VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO City VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO City VALUES (3,'Herat','AFG','Herat',186800);
# (remaining INSERT statements omitted)

```

You will need to make sure that MySQL uses the NDB storage engine for this table. There are two ways that this can be accomplished. One of these is, **before** importing the table into the Cluster database, to modify its definition so that it reads (still using the **City** as an example):

```

DROP TABLE IF EXISTS City;
CREATE TABLE City (
ID int(11) NOT NULL auto_increment,
Name char(35) NOT NULL default '',
CountryCode char(3) NOT NULL default '',
District char(20) NOT NULL default '',
Population int(11) NOT NULL default '0',
PRIMARY KEY (ID)
) ENGINE=NDBCLUSTER;

INSERT INTO City VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO City VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO City VALUES (3,'Herat','AFG','Herat',186800);
# (etc.)

```

This will need to be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is simply to do a search-and-replace on the `world.sql` file and replace all instances of `TYPE=MyISAM` with `ENGINE=NDBCLUSTER`. If you do not wish to modify the file, you can also use `ALTER TABLE`; see below for particulars.

Assuming that you have already created a database named **world** on the SQL node of the cluster, you can then use the **mysql** command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the above command must be executed on the host where the SQL node is running -- in this case, on the machine with the IP address **192.168.0.20**.

To create a copy of the **world** database on the SQL node, save the file to `/usr/local/mysql/data`, then run

```
shell> cd /usr/local/mysql/data
shell> mysql world < world.sql
```

Of course, the SQL script must be readable by the **mysql** user. If you save the file to a different location, adjust the above accordingly.

It is important to note that NDB Cluster in MySQL 4.1 and MySQL 5.0 does not support autodiscovery of databases. (See Section 16.8, "Cluster Limitations in MySQL 4.1".) This means that, once the **world** database and its tables have been created on one data node, you will need to issue the command **CREATE DATABASE world**; (beginning with MySQL 5.0.2, you may use **CREATE SCHEMA world**; instead) followed by **FLUSH TABLES**; on each data node in the cluster. This will cause the node to recognise the database and read its table defini-

tions.

Running **SELECT** queries on the SQL node is no different than running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way:

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 4.1.9-max

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

If you did not modify the `ENGINE=` clauses in the table definitions prior to importing the SQL script, then you should at this point run the following commands:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Note that we simply use the default root account with its empty password here. Of course, in a production setting, you should **always** follow the standard security precautions for installing a MySQL server, including the setting of a strong root password and creation of a user account with only those privileges required to accomplish the tasks necessary for that user. For more information about these, see Section 5.6, “The MySQL Access Privilege System”.

It is worth taking into account that Cluster nodes do not make use of the MySQL privileges system when accessing one another, and setting or changing MySQL user accounts (including the root account) has no effect on interaction between nodes, only on applications accessing the SQL node.

Selecting a database and running a **SELECT** query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----+-----+
| Name      | Population |
+-----+-----+
| Bombay    | 10500000  |
| Seoul     | 9981619   |
| São Paulo | 9968485   |
| Shanghai  | 9696300   |
| Jakarta   | 9604900   |
+-----+-----+
5 rows in set (0.34 sec)

mysql> \q
Bye

shell>
```

Applications using MySQL can use standard APIs. It is important to remember that your application must access the SQL node, and not the MGM or storage nodes. This brief example shows how we might execute the same query as above using PHP 5's `mysqli` extension running on a Web server elsewhere on the network:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
"http://www.w3.org/TR/html4/loose.dtd">
<html>
```

```

<head>
  <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
  <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
  # connect to SQL node:
  $link = new mysqli('192.168.0.20', 'root', '', 'world');
  # parameters for mysqli constructor are:
  #   host, user, password, database

  if( mysqli_connect_errno() )
    die("Connect failed: " . mysqli_connect_error());

  $query = "SELECT Name, Population
            FROM City
            ORDER BY Population DESC
            LIMIT 5";

  # if no errors...
  if( $result = $link->query($query) )
  {
?>
<table border="1" width="40%" cellpadding="4" cellspacing="1">
  <tbody>
  <tr>
    <th width="10%">City</th>
    <th>Population</th>
  </tr>
?>
  # then display the results...
  while($row = $result->fetch_object())
    printf("<tr>\n  <td align=\"center\">%s</td><td>%d</td>\n</tr>\n",
          $row->Name, $row->Population);
?>
  </tbody>
</table>
?>
  # ...and verify the number of rows that were retrieved
  printf("<p>Affected rows: %d</p>\n", $link->affected_rows);
  }
  else
    # otherwise, tell us what went wrong
    echo mysqli_error();

  # free the result set and the mysqli connection object
  $result->close();
  $link->close();
?>
</body>
</html>

```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL AB's Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

- Also remember that all NDB tables must have a primary key. If no primary key is defined by the user when a table is created, the NDB Cluster storage engine will automatically generate a hidden one. (**Note:** This hidden key takes up space just as does any other table index. It is not uncommon to encounter problems due to insufficient memory to accommodate these automatically created keys.)

16.3.6. Safe Shutdown and Restart

To shut down the cluster simply enter the following in a shell on the machine hosting the MGM node:

```
shell> ndb_mgm -e shutdown
```

This will cause the **ndb_mgm**, **ndb_mgm**, and any **ndbd** processes to terminate gracefully. Any SQL nodes can be terminated using **mysqladmin shutdown** and other means.

To restart the cluster, simply run these commands:

- On the management host (192.168.0.10 in our setup):

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40):

```
shell> ndbd
```

Remember **not** to invoke this command with the `--initial` option when restarting an NDBD node normally.

- And on the SQL host (192.168.0.20):

```
shell> mysqld &
```

For information on making backups, see Section 16.6.4.2, “Using The Management Server to Create a Backup”.

To restore the cluster from backup requires the use of the **ndb_restore** command. This is covered in Section 16.6.4.3, “How to Restore a Cluster Backup”.

More information on configuring MySQL Cluster can be found in Section 16.4, “MySQL Cluster Configuration”.

16.4. MySQL Cluster Configuration

A MySQL server that is part of a MySQL Cluster differs in only one respect from a normal (non-clustered) MySQL server, in that it employs the NDB Cluster storage engine. This engine is also referred to simply as **NDB**, and the two forms of the name are synonymous.

In order to avoid unnecessary allocation of resources, the server is configured by default with the NDB storage engine disabled. To enable NDB, you will need to modify the server's `my.cnf` configuration file, or start it with the `--ndbcluster` option.

Since the MySQL server is a part of the cluster, it will also need to know how to access an MGM node in order to obtain the cluster configuration data. The default behavior is to look for the MGM node on `localhost`. However, should you need to specify its location elsewhere, this can be done in `my.cnf` or on the MySQL server command line. Before the NDB storage engine can be used, at least one MGM node must be operational, as well as any desired data nodes.

16.4.1. Building from Source Code

NDB, the Cluster storage engine, is available in binary distributions beginning with MySQL-Max 4.1.3 for Linux, Mac OS X, and Solaris. It is not yet supported on Windows, but we intend to make it available for win32 and other platforms in the near future.

If you choose to build from a source tarball or the MySQL 4.1 BitKeeper tree, be sure to use the `--with-ndbcluster` option when running `configure`. You can also use the **BUILD/compile-pentium-max** build script. Note that this script includes OpenSSL, so you must have or obtain OpenSSL to build successfully; otherwise you will need to modify **compile-pentium-max** to exclude this requirement. Of course, you can also just follow the standard instructions for compiling your own binaries, then perform the usual tests and installation procedure. See Section 2.8.3, “Installing from the Development Source Tree”.

16.4.2. Installing the Software

In the next few sections, we assume that you are already familiar with installing MySQL, and here we cover only the differences between configuring MySQL Cluster and configuring MySQL without clustering. (See Chapter 2, *Installing MySQL* if you require more information about the latter.)

You will find Cluster configuration easiest if you have already have all management and data nodes running first; this is likely to be the most time-consuming part of the configuration. Editing the `my.cnf` file is fairly straightforward, and this section will cover only any differences from configuring MySQL without clustering.

16.4.3. Quick Test Setup of MySQL Cluster

In order to familiarise you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system root user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` with the following information, substituting appropriate values for `HostName` and `DataDir` as necessary for your system.

```
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: DB, API, and MGM are aliases for NDBD, MYSQLD, and NDB_MGMD
# respectively. DB and API are deprecated and should not be used in new
# installations.
[NDBD DEFAULT]
NoOfReplicas= 1

[MYSQLD DEFAULT]
[NDB_MGMD DEFAULT]
[TCP DEFAULT]

[NDB_MGMD]
HostName= myhost.example.com

[NDBD]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[MYSQLD]
[MYSQLD]
[MYSQLD]
```

You can now start the management server as follows:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single DB node by running **ndbd**. When starting **ndbd** for a given DB node for the very first time, you should use the `--initial` option as shown here:

```
shell> ndbd --initial
```

For subsequent **ndbd** starts, you will generally **not** want to use this option:

```
shell> ndbd
```

This is because the `--initial` option will delete all existing data and log files (as well as all table metadata) for this data node and create new ones. One exception to this rule is when restarting the cluster and restoring from backup after adding new data nodes.

By default, **ndbd** will look for the management server at `localhost` on port 1186. (Prior to MySQL 4.1.8, the default port was 2200.)

Note: If you have installed MySQL from a binary tarball, you will need to specify the path of the **ndb_mgmd** and **ndbd** servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, go to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysqld_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 4.1.7

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SHOW ENGINES;
+-----+-----+-----+-----+
| Engine      | Support | Comment                                     |
+-----+-----+-----+-----+
| NDBCLUSTER  | DEFAULT | Clustered, fault-tolerant, memory-based tables |
| NDB         | YES     | Alias for NDBCLUSTER                       |
+-----+-----+-----+-----+
```

```
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
***** 1. row *****
      Table: ctest
Create Table: CREATE TABLE `ctest` (
  `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client as shown:

```
shell> ndb_mgm
```

You can then use the **SHOW** command from within the management client in order to obtain a report on the cluster's status:

```
NDB> SHOW
Cluster Configuration
-----
[nbdb(NDB)]      1 node(s)
id=2      @127.0.0.1 (Version: 3.5.3, Nodegroup: 0, Master)

[ndb_mgmd(MGM)] 1 node(s)
id=1      @127.0.0.1 (Version: 3.5.3)

[mysqld(API)]   3 node(s)
id=3      @127.0.0.1 (Version: 3.5.3)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

16.4.4. Configuration File

Configuring MySQL Cluster requires working with two files:

- `my.cnf`: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.
- `config.ini`: This file is read only by the MySQL Cluster management server, which then distributes the information contained in this file to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster.

We are continuously making improvements in Cluster configuration and attempting to simplify this process. While we strive to maintain backwards compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backwards compatible. If you find such a change which we have not documented, please use our Bugs Database [<http://bugs.mysql.com/>] to report it.

16.4.4.1. Example Configuration for a MySQL Cluster

In order to support MySQL Cluster, you will need to update `my.cnf` as shown in the example below.

From version 4.1.8 some simplifications in `my.cnf` were made, including new sections for `ndb-cluster` executables. However, these should not be confused with those occurring in `config.ini` files. As always, you may specify these parameters when invoking those executables from the command line.

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (valid from 4.1.8)

# enable ndbcluster storage engine, and provide connectstring for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connectstring for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connectstrings, see Section 16.4.4.2, “The MySQL Cluster connect-string”).

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connectstring for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

Also starting with MySQL 4.1.8, the `my.cnf` file supports a separate `[mysql_cluster]` section for settings to be read by and affecting all executables in the cluster:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

Currently the configuration file is in INI format, and is named `config.ini` by default. It is read by **ndb_mgmd** at startup and can be placed anywhere. Its location and name are specified by using `--config-file=[<path>]<filename>` on the command line with **ndb_mgmd**. If the configuration file is not specified, **ndb_mgmd** will by default try to read a `config.ini` file located in the current working directory.

Default values are defined for most parameters, and can also be specified in `config.ini`. To create a default value section, simply add the word `DEFAULT` to the section name. For example, data nodes are configured using `[NDBD]` sections. If all data nodes use the same data memory size, and this is not the same as the default size, create an `[NDBD DEFAULT]` section containing a `DataMemory` line to specify the default data memory size for all data nodes.

The INI format consists of sections preceded by section headings (surrounded by square brackets),

followed by the appropriate parameter names and values. One deviation from the standard format is that the parameter name and value can be separated by a colon (':') as well as the equals sign ('='); another is that sections are not uniquely identified by name. Instead, unique entries (such as two different nodes of the same type) are identified by a unique ID.

At a minimum, the configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown below:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the management
# server)
# The first MySQL Server can be started from any host. The second can be started
# only on the host mysqld_5.mysql.com

[NDBD DEFAULT]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[NDB_MGMD]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[NDBD]
HostName= ndbd_2.mysql.com

[NDBD]
HostName= ndbd_3.mysql.com

[MYSQLD]
[MYSQLD]
HostName= mysqld_5.mysql.com
```

There are six different sections in this configuration file:

- [COMPUTER]: Defines the the cluster hosts.
- [NDBD]: Defines the cluster's data nodes.
- [MYSQLD]: Defines the cluster's MySQL server nodes.
- [MGM|NDB_MGMD]: Defines the management server node in the cluster.
- [TCP]: Defines TCP/IP connections between nodes in the cluster, with TCP/IP being the default connection protocol.
- [SHM]: Defines shared-memory connections between nodes. Prior to MySQL 4.1.9, this type of connection was available only in binaries that were built using the `--with-ndb-shm` option. Beginning with MySQL 4.1.9-max, it is enabled by default, but should still be considered experimental.

Note that each node has its own section in the `config.ini`. For instance, since this cluster has two data nodes, the configuration file contains two sections defining these nodes.

One can define `DEFAULT` values for each section. As of MySQL 4.1.5, all parameter names are case-insensitive.

16.4.4.2. The MySQL Cluster `connectstring`

With the exception of the MySQL Cluster management server (`ndb_mgmd`), each node making up a MySQL Cluster requires a `connectstring` which points to the management server's location. This

is used in establishing a connection to the management server as well as in performing other tasks depending on the node's role in the cluster. The syntax for a connectstring is as follows:

```
<connectstring> :=
[<nodeid-specification> , ]<host-specification> [ , <host-specification> ]
<nodeid-specification> := nodeid=<id>
<host-specification> := <host> [ : <port> ]
```

<id> is an integer larger than 1 identifying a node in config.ini <port> is an integer referring to a regular unix port <host> is a string which is a valid Internet host address

```
example 1 (long):      "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):    "myhost1"
```

All nodes will use localhost:1186 as the default connectstring value if none is provided. If <port> is omitted from the connectstring, the default port is 1186. (**Note:** Prior to MySQL 4.1.8, the default port was 2200.) This port should always be available on the network, since it has been assigned by IANA for this purpose (see <http://www.iana.org/assignments/port-numbers> for details).

By listing multiple <host-specification> values, it is possible to designate several redundant management servers. A cluster node will attempt to contact successive management servers on each host in the order specified, until a successful connection has been established.

There are a number of different ways to specify the connectstring:

- Each executable has its own command line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
- Beginning with MySQL 4.1.8, it is also possible to set the connectstring for all nodes in the cluster at once by placing it in a [mysql_cluster] section in the management server's my.cnf file.
- For backwards compatibility, two other options are available, using the same syntax:
 1. Set the NDB_CONNECTSTRING environment variable to contain the connectstring.
 2. Write the connectstring for each executable into a text file named Ndb.cfg and place this file in the executable's startup directory.

The recommended method for specifying the connectstring is to set it on the command line or in the my.cnf file for each executable.

16.4.4.3. Defining the Computers Making up a MySQL Cluster

The [COMPUTER] section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- [COMPUTER]Id

This is an integer value, used to refer to the host computer elsewhere in the configuration file.

- [COMPUTER]HostName

This is the computer's hostname or IP address.

16.4.4.4. Defining the MySQL Cluster Management Server

The [NDB_MGMD] section (or its alias [MGM]) is used to configure the behavior of the management server. Either the ExecuteOnComputer or HostName parameter must be present. All oth-

er parameters in the following can be omitted and, if so, will assume their default values.

- [NDB_MGMD]Id

Each node in the cluster has a unique identity, which is represented by an integer value in the range 1 to 63 inclusive. This ID is used by all internal cluster messages for addressing the node.

- [NDB_MGMD]ExecuteOnComputer

This refers to one of the computers defined in the [COMPUTER] section.

- [NDB_MGMD]PortNumber

This is the port number on which the management server listens for configuration requests and management commands.

- [NDB_MGMD]LogDestination

This parameter specifies where to send cluster logging information. There are three options in this regard: `CONSOLE`, `SYSLOG`, and `FILE`:

- `CONSOLE` outputs the log to `stdout`:

```
CONSOLE
```

- `SYSLOG` sends the log to a `syslog` facility, possible values being one of `auth`, `authpriv`, `cron`, `daemon`, `ftp`, `kern`, `lpr`, `mail`, `news`, `syslog`, `user`, `uucp`, `local0`, `local1`, `local2`, `local3`, `local4`, `local5`, `local6`, or `local7`.

Note: Not every facility is necessarily supported by every operating system.

```
SYSLOG:facility=syslog
```

- `FILE` pipes the cluster log output to a regular file on the same machine. The following values can be specified:

- `filename`: The name of the logfile.
- `maxsize`: The maximum size to which the file can grow before logging rolls over to a new file. When this occurs, the old logfile is renamed by appending `.x` to the filename, where `x` is the next number not yet used with this name.
- `maxfiles`: The maximum number of logfiles.

```
FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
```

It is possible to specify multiple log destinations as shown here, using a semicolon-delimited string:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

The default value for the `FILE` parameter is `FILE:filename=ndb_<id>_cluster.log,maxsize=1000000,maxfiles=6`, where `<id>` is the ID of the node.

- [NDB_MGMD]ArbitrationRank

This parameter is used to define which nodes can act as arbitrators. Only MGM nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- 0: The node will never be used as an arbitrator.
- 1: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- 2: Indicates a low-priority node which be used as an arbtrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default value) and that of all SQL nodes to 0.

- `[NDB_MGMD]ArbitrationDelay`

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- `[NDB_MGMD]DataDir`

This sets the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's pid file. (For log files, this can be overridden by setting the `FILE` parameter for `[NDB_MGMD]LogDestination` as discussed previously in this section.)

16.4.4.5. Defining MySQL Cluster Data Nodes

The `[NDBD]` section is used to configure the behavior of the cluster's data nodes. There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameters are:

- Either `ExecuteOnComputer` or `HostName`.
- The parameter `NoOfReplicas`

These need to be defined in the `[NDBD DEFAULT]` section.

Most data node parameters are set in the `[NDBD DEFAULT]` section. Only those parameters explicitly stated as being able to set local values are allowed to be changed in the `[NDBD]` section. `HostName`, `Id` and `ExecuteOnComputer` *must* be defined in the local `[NDBD]` section.

Identifying Data Nodes

The `Id` value (that is, the the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

For each parameter it is possible to use `k`, `M`, or `G` as a suffix to indicate units of 1024, 1024*1024, or 1024*1024*1024. (For example, 100k means 100 * 1024 = 102400.) Parameters and values are currently case-sensitive.

- `[NDBD]Id`

This is the node ID used as the address of the node for all cluster internal messages. This is an integer between 1 and 63. Each node in the cluster has a unique identity.

- `[NDBD]ExecuteOnComputer`

This refers to one of the computers (hosts) defined in the `COMPUTER` section.

- [NDBD]HostName

Specifying this parameter has an effect similar to specifying `ExecuteOnComputer`. It defines the hostname of the computer the storage node on which is to reside. Either this parameter or `ExecuteOnComputer` is required.

- [NDBD]ServerPort

Each node in the cluster will use one port as the port other nodes use to connect the transporters to each other. This port is used also for non-TCP transporters in the connection setup phase. The default port will be calculated to ensure that no nodes on the same computer receive the same port number.

- [NDBD]NoOfReplicas

This global parameter can be set only in the [NDBD DEFAULT] section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes that all store the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer, as in this situation a single hardware failure would cause the entire cluster to crash.

If no node IDs are provided then the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

There is no default value for `NoOfReplicas`; the maximum possible value is 4.

- [NDBD]DataDir

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

- [NDBD]FileSystemPath

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs and data files are placed. The default is the directory specified by `DataDir`. **Note:** This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for MySQL Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's filesystem is created. This subdirectory contains the node ID. For example, if the node ID is 2, then this subdirectory is named `ndb_2_fs`.

- [NDBD]BackupDataDir

It is also possible to specify the directory in which backups are placed. By default, this directory is `FileSystemPath/BACKUP`. (See above.)

Data Memory and Index Memory

`DataMemory` and `IndexMemory` are parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` and `IndexMemory` are used, as they usually need to be updated in order to reflect actual usage by the cluster:

- [NDBD]DataMemory

This parameter defines the amount of space available to store database records. The entire amount will be allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate this value.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. Each record is currently of fixed size. (Even `VARCHAR` columns are stored as fixed-width columns.) There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page. The maximum record size is currently 8052 bytes.

The memory space defined by `DataMemory` is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory`, but this is not the case: only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory`. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`. Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. Performing a node recovery also will compress the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2-4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason. In addition, it is also possible to run more than one `ndbd` process per machine, and this may prove advantageous on machines with multiple CPUs.

- [NDBD] `IndexMemory`

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. Note that when defining a primary key and a unique index, two indexes will be created, one of which is a hash index used for all tuple accesses as well as lock handling. It is also used to enforce unique constraints.

The size of the hash index is 25 bytes per record, plus the size of the primary key. For primary

keys larger than 32 bytes another 8 bytes is added.

Consider a table defined by

```
CREATE TABLE example
(
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

There are 12 bytes overhead (having no nullable columns saves 4 bytes of overhead) plus 12 bytes of data per record. In addition we have two ordered indexes on columns **a** and **b** consuming about 10 bytes each per record. There is a primary key hash index on the base table with roughly 29 bytes per record. The unique constraint is implemented by a separate table with **b** as primary key and **a** as a column. This table will consume another 29 bytes of index memory per record in the **example** table as well as 12 bytes of overhead, plus 8 bytes of record data.

Thus, for one million records, we need 58 MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64 MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

Currently the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with 2 replicas, then there will be two node groups. Thus, the total data memory available is $2 * \text{DataMemory}$ for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Since data is distributed evenly over all nodes in the cluster the maximum amount of space available is no better than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be quite okay, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, then restarting the management server followed by restarting each data node in turn.

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

The default value for `IndexMemory` is 18MB. The minimum is 1MB.

Transaction Parameters

The next three parameters which we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node; `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, in order to ensure that these do not use excessive memory.

- `[NDBD]MaxNoOfConcurrentTransactions`

For each active transaction in the cluster there must be a record in one of the cluster nodes. The task of co-ordinating transactions is spread amongst the nodes: the total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Normally there is at least one transaction record allocated per connection that using any table in the cluster. For this reason, one should ensure that there are more transaction records in the cluster than there are concurrent connections to all MySQL servers in the cluster.

This parameter must be set to the same value for all cluster nodes.

Changing this parameter is never safe and can cause a cluster to crash. When a node crashes one of the node (actually the oldest surviving node) will build up the transaction state of all transactions ongoing in the crashed node at the time of the crash. It is thus important that this node has as many transaction records as the failed node.

The default value for this parameter is 4096.

- `[NDBD]MaxNoOfConcurrentOperations`

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions of only a few operations each and not involving a great many records, there is no need to set this parameter very high. When performing large transactions involving many records need to set this parameter higher.

Records are kept for each transaction updating cluster data, both in the transaction co-ordinator and in the nodes where the actual updates are performed. These records contain state information needed in order to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has 4 data nodes and which is expected to handle 1,000,000 concurrent updates using transactions, you should set this value to $1000000 / 4 = 250000$.

Read queries which set locks also cause operation records to be created. Some extra space is allocated in the individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value for this parameter is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction co-ordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on a 8-node cluster requires as many operation records in the transaction co-ordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all 8 nodes. Thus, if it is necessary to configure the system for one very large transaction, then it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction co-ordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. In MySQL 4.1, these consume about 1KB per record. This figure is expected to be reduced in MySQL 5.x.

- [NDBD]MaxNoOfLocalOperations

By default, this parameter is calculated as $1.1 * \text{MaxNoOfConcurrentOperations}$ which fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, then it is a good idea to override the default value by explicitly specifying this parameter.

Transaction Temporary Storage

The next set of parameters is used to determine temporary storage when executing a query which is part of a Cluster transaction. All records are released when the query is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these to enable better parallelism in the system, while users whose applications require relatively small transactions can decrease the values in order to save memory.

- [NDBD]MaxNoOfConcurrentIndexOperations

For queries using a unique hash index another, temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus this record is only allocated while executing a part of a query, as soon as this part has been executed the record is released. The state needed to handle aborts and commits is handled by the normal operation records where the pool size is set by the parameter `MaxNoOfConcurrentOperations`.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree parallelism is not required for the cluster.

- [NDBD]MaxNoOfFiredTriggers

The default value of `MaxNoOfFiredTriggers` is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- [NDBD]TransactionBufferMemory

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to $4000 * 128$ bytes (500KB). A similar buffer for key info, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains $4000 * 16 = 62.5\text{KB}$ of buf-

fer space. `Dbtc` is the module which handles transaction co-ordination.

Scans and Buffering

There are additional parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) which affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to 10000*128 bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

The default value for `TransactionBufferMemory` is 1MB.

- `[NDBD]MaxNoOfConcurrentScans`

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction co-ordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain `MaxNoOfConcurrentScans` scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. Since the order is kept on the local partitions only, it is necessary to perform the index scan on all partitions.

The default value of `MaxNoOfConcurrentScans` is 256. The maximum value is 500.

This parameter specifies the number of scans possible in the transaction co-ordinator. If the number of local scan records is not provided, it is calculated as the product of `MaxNoOfConcurrentScans` and the number of data nodes in the system.

- `[NDBD]MaxNoOfLocalScans`

Specifies the number of local scan records if many scans are not fully parallelized.

- `[NDBD]BatchSizePerLocalScan`

This parameter is used to calculate the number of lock records which needs to be there to handle many concurrent scan operations.

The default value is 64; this value has a strong connection to the `ScanBatchSize` defined in the SQL nodes.

- `[NDBD]LongMessageBuffer`

This is an internal buffer used for passing messages within individual nodes and between nodes. While it is highly unlikely that this would need to be changed, it is configurable. By default it is set to 1MB.

Logging and Checkpointing

- `[NDBD]NoOfFragmentLogFiles`

This parameter sets the size of the node's REDO log files. REDO log files are organized in a ring. It is extremely important that the first and last log files (sometimes referred to as the "head" and "tail" log files, respectively) do not meet; when these approach one another too closely, the

node will begin aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until three local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 8, which means 8 sets of 4 16MB files for a total of 512MB. In other words, REDO log space must be allocated in blocks of 64MB. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher in order to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, then all updating transactions will be aborted with internal error code 410, or `Out of log file space temporarily`. This condition will prevail until a checkpoint has completed and the log tail can be moved forward.

- `[NDBD]MaxNoOfSavedMessages`

This parameter sets the maximum number of trace files that will be kept before overwriting old ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25 trace files.

Metadata Objects

The next set of parameters defines pool sizes for metadata objects. It is necessary to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters.

- `[NDBD]MaxNoOfAttributes`

Defines the number of attributes that can be defined in the cluster.

The default value for this parameter is 1000, with the minimum possible value being 32. There is no maximum. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

- `[NDBD]MaxNoOfTables`

A table object is allocated for each table, unique hash index, and ordered index. This parameter sets the maximum number of table objects for the cluster as a whole.

For each attribute that has a BLOB data type an extra table is used to store most of the BLOB data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 1600. Each table object consumes approximately 20KB per node.

- `[NDBD]MaxNoOfOrderedIndexes`

For each ordered index in the cluster, an object is allocated describing what is being indexed and

its storage segments. By default each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index.

The default value of this parameter is 128. Each object consumes approximately 10KB of data per node.

- [NDBD]MaxNoOfUniqueHashIndexes

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default there an ordered index is also defined for each unique index. To prevent this, you must use the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

- [NDBD]MaxNoOfTriggers

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that 3 triggers are created for each unique hash index.) However, an **ordered** index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Note: When replication between clusters is supported, this will also make use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value for this parameter is 768.

- [NDBD]MaxNoOfIndexes

This parameter was deprecated in MySQL 4.1.5. In MySQL 4.1.6 and newer versions, you should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

Boolean Parameters

The behavior of data nodes is also affected by a set of parameters taking on boolean values. These parameters can be specified as **TRUE** by setting them equal to **1** or **Y**, and as **FALSE** by setting them equal to **0** or **N**.

- [NDBD]LockPagesInMainMemory

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

By default, this feature is disabled.

- [NDBD]StopOnError

This parameter specifies whether an NDBD process is to exit or to perform an automatic restart when an error condition is encountered.

This feature is enabled by default.

- [NDBD]Diskless

It is possible to specify Cluster tables as **diskless**, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables will be preserved after a crash. However, when operating in diskless mode, it is possible to run **ndbd** on a diskless computer.

This feature makes the entire cluster operate in diskless mode. We plan to add the capability to employ diskless mode on a per-table basis in a future (5.0 or 5.1) release of MySQL Cluster.

Currently, when this feature is enabled, backups are performed but backup data is not actually stored. In a future release we hope to make diskless backup a separate, configurable parameter.

This feature is enabled by setting `Diskless` to either `1` or `y`. `Diskless` is disabled by default.

- `[NDBD]RestartOnErrorInsert`

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

By default, this feature is disabled.

Controlling Timeouts, Intervals, and Disk Paging

There are a number of parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this will be mentioned below.

- `[NDBD]TimeBetweenWatchDogCheck`

To prevent the main thread from getting stuck in an endless loop at some point, a "watch dog" thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, it is terminated by the watch dog thread.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node nodes although there seems to be little reason for doing so.

The default timeout is 4000 milliseconds (4 seconds).

- `[NDBD]StartPartialTimeout`

This parameter specifies the time that the cluster will wait for all storage nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

The default value is 30000 milliseconds (30 seconds). `0` means eternal time out; in other words, the cluster may start only if all nodes are available.

- `[NDBD]StartPartitionedTimeout`

If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still in a possibly partitioned state, the cluster waits until this timeout has also passed.

The default timeout is 60000 milliseconds (60 seconds).

- `[NDBD]StartFailureTimeout`

If a data node has not completed its startup sequence within the time specified by this parameter, then the node startup will fail. Setting this parameter to `0` means that no data node timeout is applied.

The default value is 60000 milliseconds (60 seconds). For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a storage node containing several gigabytes of data, a period as long as 10-15 minutes (that is, 600,000 to 1,000,000 milliseconds) might be required in order to to perform a node restart.

- `[NDBD]HeartbeatIntervalDbDb`

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

The default heartbeat interval is 1500 milliseconds (1.5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds then obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade but only in small increments.

- `[NDBD]HeartbeatIntervalDbApi`

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared "dead", in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until the completion of all activities started by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for `HeartbeatIntervalDbDb`.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each storage node watches the MySQL servers connected to it, independently of all other data nodes.

- `[NDBD]TimeBetweenLocalCheckpoints`

This parameter is an exception in that it doesn't specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB ($4 * (2 ^ 20)$) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- `[NDBD]TimeBetweenGlobalCheckpoints`

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases -- a complete crash of the cluster -- is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group; later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster as well.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- [NDBD]TimeBetweenInactiveTransactionAbortCheck

Time-out handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, then every transaction will be checked for timing out once per second.

The default value for this parameter is 1000 milliseconds (1 second).

- [NDBD]TransactionInactiveTimeout

If the transaction is currently not performing any queries but is waiting for further user input, this parameter states the maximum time that the user can wait before the transaction is aborted.

The default for this parameter is zero (no timeout). For a real-time database that needs to ensure that no transaction keeps locks for too long a time this parameter should be set to a much smaller value. The unit is milliseconds.

- [NDBD]TransactionDeadlockDetectionTimeout

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

1. The node is "dead"
2. The operation has entered a lock queue
3. The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator will wait for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection. Setting it too high can cause a undesirable behavior in situations involving deadlocks and node failure.

The default timeout value is 1200 milliseconds (1.2 seconds).

- [NDBD]NoOfDiskPagesToDiskAfterRestartTUP

When executing a local checkpoint the algorithm flushes all data pages to disk. Merely doing as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a "page" is defined as 8KB; thus, this parameter is specified in units of 80KB per second. Therefore, setting NoOfDiskPagesToDiskAfterRestartTUP to a value of 20 means writing 1.6MB of data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log records for data pages; that is, this parameter handles the limitation of writes from data memory. UNDO log records for index pages are handled by the parameter NoOfDiskPagesToDiskAfterRestartACC. (See the entry for IndexMemory for information about index pages.)

In short, this parameter specifies how quickly local checkpoints will be executed, and operates in conjunction with NoOfFragmentLogFiles, DataMemory, and IndexMemory.

The default value is 40 (3.2MB of data pages per second).

- [NDBD]NoOfDiskPagesToDiskAfterRestartACC

This parameter uses the same units as `NoOfDiskPagesToDiskAfterRestartTUP` and acts in a similar fashion, but limits the speed of writing index pages from index memory.

The default value of this parameter is 20 index memory pages per second (1.6MB per second).

- `[NDBD]NoOfDiskPagesToDiskDuringRestartTUP`

This parameter in a similar fashion as `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, only it does so with regard to local checkpoints executed in the node when a node is restarting. As part of all node restarts a local checkpoint is always performed. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.

This parameter covers pages written from data memory.

The default value is 40 (3.2MB per second).

- `[NDBD]NoOfDiskPagesToDiskDuringRestartACC`

Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.

As with `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).

The default value is 20 (1.6MB per second).

- `[NDBD]ArbitrationTimeout`

This parameter specifies the time that the data node will wait for a response from the arbitrator to an arbitration message. If this is exceeded, then it is assumed that the network has split.

The default value is 1000 milliseconds (1 second).

Buffering and Logging

Several configuration parameters corresponding to former compile-time parameters were introduced in MySQL 4.1.5. These enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front-ends to the file system when writing log records to disk. If the node is running in diskless mode, then these parameters can be set to their minimum values without penalty due to the fact that disk writes are "faked" by the NDB storage engine's filesystem abstraction layer.

- `[NDBD]UndoIndexBuffer`

This buffer is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. In order to produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to insure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, and for most applications the minimum is sufficient. For applications doing extremely large and/or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 `Index UNDO buffers overloaded`.

- `[NDBD]UndoDataBuffer`

The UNDO data buffer plays the same role as the UNDO index buffer, except that it is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Since UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

For some applications this amount of memory may be unnecessarily large. In such cases it is possible to decrease this size down to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, then it is a good idea to check if the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 `Data UNDO buffers overloaded`.

- `[NDBD]RedoBuffer`

All update activities also need to be logged. This log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a "fuzzy" checkpoint of the data together with the UNDO log, then applies the REDO log to play back all changes up to the restoration point.

This buffer is 8MB by default. The minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 `REDO log buffers overloaded`.

In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. There are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server's cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- `[NDBD]LogLevelStartup`

Reporting level for events generated during startup of the process.

The default level is 1.

- `[NDBD]LogLevelShutdown`

Reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- `[NDBD]LogLevelStatistic`
Reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.
The default level is 0.
- `[NDBD]LogLevelCheckpoint`
Reporting level for events generated by local and global checkpoints.
The default level is 0.
- `[NDBD]LogLevelNodeRestart`
Reporting level for events generated during node restart.
The default level is 0.
- `[NDBD]LogLevelConnection`
Reporting level for events generated by connections between cluster nodes.
The default level is 0.
- `[NDBD]LogLevelError`
Reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.
The default level is 0.
- `[NDBD]LogLevelInfo`
Reporting level for events generated for information about the general state of the cluster.
The default level is 0.

Backup Parameters

The parameters discussed in this section define memory buffers set aside for execution of online backups.

- `[NDBD]BackupDataBufferSize`
In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as `BackupWriteSize` (see below), the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed and have thus freed up memory so that scanning may continue.
The default value for this parameter is 2MB.
- `[NDBD]BackupLogBufferSize`
The backup log buffer fulfils a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be big enough to handle the load caused by write activities while the backup is being made.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster will be likely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value is 2MB.

- [NDBD]BackupMemory

This parameter is simply the sum of BackupDataBufferSize and BackupLogBufferSize.

The default value is 2MB + 2MB = 4MB.

- [NDBD]BackupWriteSize

This parameter specifies the size of messages written to disk by the backup log and backup data buffers.

The default value is 32KB.

16.4.4.6. Defining the SQL Nodes in a MySQL Cluster

The [MYSQLD] sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, then any host can use this SQL node.

- [MYSQLD]Id

This value is used as the address of the node by all cluster internal messages, and must be an integer between 1 and 63. Each cluster node must have a unique identity.

- [MYSQLD]ExecuteOnComputer

This refers to one of the computers (hosts) defined in a [COMPUTER] section of the configuration file.

- [MYSQLD]ArbitrationRank

This parameter is used to define which nodes can act as arbitrators. Both MGM nodes and SQL nodes can be arbitrators. A value of 0 means the given node will never be used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its ArbitrationRank to 1 (the default) and those for all SQL nodes to 0.

- [MYSQLD]ArbitrationDelay

Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- [MYSQLD]BatchByteSize

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (BatchSize) and in terms of bytes (BatchByteSize). The actual batch size will be limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set. In future releases, the MySQL Server will make educated guesses on how to set parameters relating to batch size, based on the query type.

This parameter is measured in bytes and by default is equal to 32KB.

- [MYSQLD]BatchSize

This parameter is measured in number of records and is by default set to 64. The maximum size is 992.

- [MYSQLD]MaxScanBatchSize

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel in order to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

16.4.4.7. MySQL Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for establishing connections in MySQL Cluster. It is normally not necessary to define connections because Cluster automatically set ups a connection between each of the data nodes, between each data node and all MySQL server nodes, and between each data node and the management server. (For one exception to this rule, see **MySQL Cluster TCP/IP Connections Using Crossover** later in this section.)

It is only necessary to define a connection in order to override the default connection parameters. In that case it is necessary to define at least *NodeId1*, *NodeId2*, and the parameters to change.

It is also possible to change the default values for these parameters by setting them in the [TCP DEFAULT] section.

- [TCP]NodeId1 , [TCP]NodeId2

To identify a connection between two nodes it is necessary to provide the node identities for both of them in the [TCP] section of the configuration file.

- [TCP]SendBufferMemory

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these is also sent when a round of messages have beenexecuted. To handle temporary overload situations it is also possible to define a bigger send buffer. The default size of the send buffer is 256KB.

- [TCP]SendSignalId

In order to be able to retrace a distributed message diagram it is necessary to identify each message. When this parameter is set to **Y**, message IDs are transported over the network. This feature is disabled by default.

- [TCP]Checksum

This parameter is also a boolean (Y/N or 1/0) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature insures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- [TCP]PortNumber

(DEPRECATED.) This is the port number to be used to listen for connections from other

nodes. This port number is normally specified in the configuration file's [TCP DEFAULT] section.

This parameter should no longer be used. Use the `ServerPort` instead.

- [TCP]ReceiveBufferMemory

Specifies the size of the buffer used when receiving data from the TCP/IP socket. There is seldom any need to change this parameter from its default value of 64KB, except possibly in order to save memory.

16.4.4.8. MySQL Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the [TCP] section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least 4 hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the 172.23.72.* subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the 1.1.0.* address range as shown:

```
# Management Server
[NDB_MGMD]
Id=1
HostName=172.23.72.20

# SQL Node
[MYSQLD]
Id=2
HostName=172.23.72.21

# Data Nodes
[NDBD]
Id=3
HostName=172.23.72.22

[NDBD]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[TCP]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The use of direct connections between data nodes can improve the cluster's overall efficiency by allowing the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that in order to take the best advantage of direct connections in this fashion with more than 2 data nodes, you will need to have a direct connection between each data node and every other data node in the same node group.

16.4.4.9. MySQL Cluster Shared-Memory Connections

Beginning with MySQL 4.1.9-max, MySQL Cluster will attempt to use the shared memory transporter and configure it automatically where possible, chiefly where more than one node runs concurrently on the same cluster host. (In previous versions of MySQL Cluster, shared memory segments were supported only when the `-max` binary was built using `--with-ndb-shm`.) When explicitly

defining shared memory as the connection method it is necessary to define at least `NodeId1`, `NodeId2` and `ShmKey`. All other parameters have default values that will work out fine in most cases.

Note: SHM support should still be considered experimental in MySQL 4.1.

- `[SHM]NodeId1` , `[SHM]NodeId2`

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `[SHM]ShmKey`

When setting up shared memory segments, a node ID is used to identify uniquely the shared memory segment to use for the communication. This is expressed as an integer which does not have a default value.

- `[SHM]ShmSize`

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 1MB.

- `[SHM]SendSignalId`

In order to retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to **Y** causes these message IDs to be transported over the network as well. This feature is disabled by default.

- `[SHM]Checksum`

This parameter is also a Y/N parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

16.4.4.10. MySQL Cluster SCI Transport Connections

Using SCI transporters to connect nodes in a MySQL Cluster is supported only when the MySQL-max binaries are built using `--with-ndb-sci=/your/path/to/SCI`. The *path* should point to a directory that contains at a minimum `lib` and `include` directories containing SISI libraries and header files.

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between **ndbd** processes. In addition, using SCI Transporters means that the **ndbd** processes never sleep. For this reason, SCI Transporters should be used only on machines having at least 2 CPUs dedicated for use by **ndbd** processes. There should be at least 1 CPU per **ndbd** process, with at least 1 CPU left in reserve to handle operating system activities.

- `[SCI]NodeId1` , `[SCI]NodeId2`

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- `[SCI]Host1SciId0`

This identifies the SCI node ID on the first Cluster node (identified by `NodeId1`).

- `[SCI]Host1SciId1`

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- `[SCI]Host2SciId0`

This identifies the SCI node ID on the second Cluster node (identified by `NodeId2`).

- `[SCI]Host2SciId1`

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- `[SCI]SharedBufferSize`

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1 MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the **ndbd** process.

- `[SCI]SendLimit`

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default this is set to 8kB. Our benchmarks show that performance is best at 64 kB but 16kB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8kB.

- `[SCI]SendSignalId`

In order to trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to **Y**, message IDs are transported over the network. This feature is disabled by default.

- `[SCI]Checksum`

This parameter is also a boolean value, and is disabled by default. When `Checksum` is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

16.5. Process Management in MySQL Cluster

Understanding how to manage MySQL Cluster requires a knowledge of four essential processes. In the next few sections of this chapter, we cover the roles played by these processes in a cluster, how to use them, and what startup options are available for each of them.

16.5.1. MySQL Server Process Usage for MySQL Cluster

mysqld is the traditional MySQL server process. To be used with MySQL Cluster, **mysqld** needs to be built with support for the NDB Cluster storage engine, as it is in the precompiled `-max` binaries available from mysql.com for MySQL versions 4.1.3 and newer.

If the **mysqld** binary has been built in such a manner, the NDB Cluster storage engine is still disabled by default. You can use either of two possible options for enabling the NDB Cluster storage engine:

Use `--ndbcluster` as a startup option when starting **mysqld**

- Insert a line containing `ndbcluster` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the NDB Cluster storage engine enabled is to issue the command `SHOW ENGINES` in the MySQL Monitor (**mysql**). You should see the value `YES` in the row listing `NDBCLUSTER`; if you see `NO` in this row (or if there is no such row displayed in the output), you are not running an NDB-enabled version of **mysqld**. If you see `DISABLED` in this row, then you need to enable it in either one of the two ways shown above.

In order to read cluster configuration data, the MySQL server requires 3 pieces of information:

- The MySQL server's own cluster node ID.
- The hostname or IP address for the management server (MGM node).
- The port on which it can connect to the management server.

Beginning with MySQL 4.1.5, node IDs can be dynamically allocated, in which case there is no need to specify it explicitly.

The **mysqld** parameter `ndb-connectstring` is used to specify the connectstring either on the command line when starting **mysqld** or in `my.cnf`. The connectstring contains the hostname/IP and port where the management server can be found.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See Section 16.4.4.2, “The MySQL Cluster connectstring” for more info on connectstrings.

Given this information, the MySQL server will be a full participant in the cluster. (We sometimes refer to a **mysqld** process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to access node data for reading and updating.

16.5.2. ndbd, the Storage Engine Node Process

ndbd is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process empowers a storage node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of **ndbd** processes co-operate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

In MySQL versions prior to 4.1.5, each **ndbd** process should be started in a separate directory, the reason for this being that **ndbd** generated a set of log files in its starting directory. In MySQL 4.1.5, this behavior was changed such that the these files are placed in the directory specified by `DataDir` in the configuration file. Thus **ndbd** can be started from anywhere.

These log files are listed below. `<NodeID>` is the node's unique identifier. For example, `ndb_2_error.log` is the error log generated by the storage node whose node ID is `2`.

- `ndb_<NodeID>_error.log` (was `error.log` in version 4.1.3) is a file containing records of all crashes which the referenced **ndbd** process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```

Date/Time: Saturday 31 January 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***

```

- `ndb_<NodeID>_trace.log.<TraceID>` (was `NDB_TraceFile_<TraceID>.trace` in version 4.1.3) is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.

It is possible to configure the number of these trace files that will be created before old files are overwritten. `<TraceID>` is a number which is incremented for each successive trace file.

- `ndb_<NodeID>_trace.log.next` (was `NextTraceFileNo.log` in version 4.1.3) is the file that keeps track of the next trace file number to be assigned.
- `ndb_<NodeID>_out.log` is a file containing any data output by the **ndbd** process. This file is created only if **ndbd** is started as a daemon, which is the default behavior beginning with MySQL 4.1.5. This file was named `node<NodeID>.out` in versions 4.1.3 and 4.1.4.
- `ndb_<NodeID>.pid` is a file containing the process ID of the **ndbd** process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
- `ndb_<NodeID>_signal.log` (was `Signal.log` in version 4.1.3) is a file used only in debug versions of **ndbd**, where it is possible to trace all incoming, outgoing, and internal messages with their data in the **ndbd** process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the pid-file remains in effect even after the process has terminated.

When starting **ndbd** it may also be necessary to specify the hostname of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

(See Section 16.4.4.2, “The MySQL Cluster `connectstring`” for additional information about this issue.)

When **ndbd** starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution of the execution process has been completed, and then to restart the **ndbd** process if it is configured to do so. Thus, if you attempt to kill **ndbd** via the Unix **kill** command, it is necessary to kill both processes. A more proper way to terminate an **ndbd** process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent activities. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the **ndbd** process. In a system performing a large number of operations, including updates, the **ndbd** process can consume up to 2 CPUs if permitted to do so. For a machine with many CPUs it is recommended to use several **ndbd** processes which belong to different node groups.

16.5.3. `ndb_mgmd`, the Management Server Process

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

As of MySQL 4.1.5, it is no longer necessary to specify a connectstring when starting the management server. However, if you are using more than one management server, a connectstring should be provided and each node in the cluster should specify its node ID explicitly.

The following files are created or used by `ndb_mgmd` in its starting directory. From MySQL 4.1.5, the log and PID files are placed in the `DataDir` as specified in the configuration file. In the list that follows, `<NodeID>` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. Setting up this file is discussed in Section 16.4, “MySQL Cluster Configuration”.
- `ndb_<NodeID>_cluster.log` (was `cluster.log` in version 4.1.3) is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 16.6, “Management of MySQL Cluster”.

When the size of the cluster log reaches one million bytes then the file is renamed to `ndb_<NodeID>_cluster.log.SeqID` (was `cluster.log.SeqID` where `SeqID` is the sequence number of the cluster log file. (For example: If 1, 2, and 3 already exist, the next log file will be named using the number 4.)

- `ndb_<NodeID>_out.log` (was `node1.out` in version 4.1.3) is the file used for `stdout` and `stderr` when running the management server as a daemon.
- `ndb_<NodeID>.pid` (was `node<NodeID>.pid` in version 4.1.3) is the PID file used when running the management server as a daemon.

16.5.4. `ndb_mgm`, the Management Client Process

The management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client access the management server using a C API that advanced users can also employ for programming dedicated management processes which can perform tasks similar to those performed by `ndb_mgm`.

When starting the management client, it is necessary to supply the hostname and port of the management server as in the example below. The default values are `localhost` and `1186` (prior to MySQL 4.1.8, the default Cluster port was 2200).

```
shell> ndb_mgm localhost 1186
```

Additional information about using `ndb_mgm` can be found in Section 16.5.5.4, “Command Options for `ndb_mgm`” and Section 16.6.1, “Commands in the Management Client”.

16.5.5. Command Options for MySQL Cluster Processes

All MySQL Cluster executables (except for `mysqld`) take the following options as of 4.1.8. If you are using an earlier version, please read carefully, as we have made changes in some of these switches in order to make them consistent with one another as well as with `mysqld`. (For example, the `-V` switch was `-v` in earlier versions.) You can also use the `-?` option to see what is supported in your version.

- `-?, --usage, --help`

Prints a short list with descriptions of the available command options.

- `-V, --version`

Prints the version number of the **ndbd** process. The version number is the MySQL Cluster version number. The version number is relevant because not all versions can be used together, and at startup the MySQL Cluster processes verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online software upgrade of MySQL Cluster (see *Software Upgrade of MySQL Cluster*).

- `-c connect_string, --connect-string`

connect_string Sets the connect string to the management server as a command option. (for reasons of backwards compatibility, **ndb_mgmd** does not accept the `-c` option before MySQL 5.0, as this switch specifies the configuration file in previous versions). Available with **ndb_mgm** from MySQL 4.1.8 onwards.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

- `--debug[=options]`

This option can only be used for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the **mysqld** process.

16.5.5.1. MySQL Cluster-Related Command Options for **mysqld**

- `--ndbcluster`

If the binary includes support for the NDB Cluster storage engine the default disabling of support for the NDB storage engine can be overridden by using this option. Use of the NDB Cluster storage engine is necessary for using MySQL Cluster.

- `--skip-ndbcluster`

Disables the NDB Cluster storage engine. This is disabled by default for binaries where it is included; the option only applies if the server was configured to use the NDB Cluster storage engine.

- `--ndb-connectstring=connect_string`

When using the NDB storage engine, it is possible through setting this option to specify the management server that distributes cluster configuration data.

16.5.5.2. Command Options for **ndbd**

For some common options see Section 16.5.5, “Command Options for MySQL Cluster Processes”.

- `-d, --daemon`

Instructs **ndbd** to execute as a daemon process. From MySQL 4.1.5 on, this is the default behavior.

- `--nodaemon`

Instructs **ndbd** not to start as a daemon process. Useful when **ndbd** is being debugged and one wants output redirected to the screen.

- `--initial`

Instructs **ndbd** to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of **ndbd**. It also re-creates recovery log files. Note that on some operating systems this process can take a substantial amount of time.

An `--initial` start is to be used only the very first time that the **ndbd** process is started, as it removes all files from the Cluster filesystem and re-creates all REDO log files. The exceptions to this rule are:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of **ndbd**.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case be aware that that this node can no longer be used to restore data due to the destruction of the datafiles.

This option does not affect any backup files that have been created by the affected node.

In older versions of MySQL Cluster, it was possible to use `-i` for this option. This shortcut was removed to prevent this option from being used by mistake.

- `--nostart`

Instructs **ndbd** not to start automatically. When this option is used, **ndbd** connects to the management server, obtains configuration data from it, and initialises communication objects. However, it will not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper command to the management client.

16.5.5.3. Command Options for `ndb_mgmd`

For some common options see Section 16.5.5, “Command Options for MySQL Cluster Processes”.

- `-f filename, --config-file=filename, -c filename`

Instructs the management server as to which file it should use for its configuration file. This option must be specified. The file name defaults to `config.ini`. The `-f` shortcut is available beginning with MySQL Cluster 4.1.8. The `-c` shortcut became obsolete in MySQL Cluster 5.0.

- `-d, --daemon`

Instructs **ndb_mgmd** to start as a daemon. This is the default behavior.

- `-nodaemon`

Instructs the management server not to start as a daemon.

16.5.5.4. Command Options for `ndb_mgm`

For some common options see Section 16.5.5, “Command Options for MySQL Cluster Processes”.

- `[host_name [port_num]]`

To start the management client it is necessary to specify where the management server resides, which means specifying the hostname and the port. The default hostname is `localhost` and the default port is 1186 (this was port 2200 prior to version 4.1.8).

- `--try-reconnect=number`

If the connection to the management server is broken, then the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to *number* before giving up and reporting an error instead.

16.6. Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in Section 16.4, “MySQL Cluster Configuration” and Section 16.5, “Process Management in MySQL Cluster”.

The following sections cover the management of a running MySQL Cluster.

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be checked, log levels changed, backups started and stopped and nodes stopped and started. The second method involves studying the contents of the cluster log `ndb_<NodeID>_cluster.log` in the management server's `DataDir` directory. (Recall that `<NodeID>` represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by `ndbd`. It is also possible to send cluster log entries to a Unix system log.

16.6.1. Commands in the Management Client

In addition to the central configuration file, a cluster may also be controlled through a command line interface available through the management client `ndb_mgm`. This is the primary administrative interface to a running cluster.

The management client has the following basic commands. In the listing that follows, `<id>` denotes either a database node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- `HELP`
Displays information on all available commands.
- `SHOW`
Displays information on the cluster's status.
- `<id> START`
Starts the data node identified by `<id>` (or all data nodes).
- `<id> STOP`
Stops the data node identified by `<id>` (or all data nodes).
- `<id> RESTART [-N] [-I]`
Restarts the data node identified by `<id>` (or all data nodes).
- `<id> STATUS`
Displays status information for the data node identified by `<id>` (or for all data nodes).
- `ENTER SINGLE USER MODE <id>`
Enters single-user mode, whereby only the MySQL server identified by the node ID `<id>` is allowed to access the database.

- `EXIT SINGLE USER MODE`

Exists single user mode allowing all SQL nodes (that is, all running **mysqld** processes) to access the database.

- `QUIT`

Terminates the management client.

- `SHUTDOWN`

Shuts down all cluster nodes, except for SQL nodes, and exits.

Commands for the event logs are given in the next section; commands for creating backups and restoring from backup are provided in a separate section on these topics.

16.6.2. Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.

MySQL Cluster provides two types of event log. These are the **cluster log**, which includes events generated by all cluster nodes, and **node logs**, which are local to each data node.

Output generated by cluster event logging can have multiple destinations including a file, the management server console window, or `syslog`. Output generated by node event logging is written to the data node's console window.

Both sorts of event logs can be set to log different subsets of events.

Note: The cluster log is the log recommended for most uses, since it provides logging information for an entire cluster in a single file. Node logs are intended to be used only during application development, or for debugging application code.

Each reportable event can be distinguished according to 3 different criteria:

- *Category:* This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.
- *Priority:* This is represented by a number 1 to 15 inclusive, where 1 indicates "most important" and 15 "least important".
- *Severity Level:* This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

16.6.2.1. Logging Management Commands

The following management commands are related to the cluster log:

- `CLUSTERLOG ON`

Turn cluster log on.

- `CLUSTERLOG OFF`

Turn cluster log off.

- CLUSTERLOG INFO

Information about cluster log settings.

- `<id> CLUSTERLOG <category>=<threshold>`

Logs *category* events with priority less than or equal to *threshold* in the cluster log.

- CLUSTERLOG FILTER *<severity>*

Toggles cluster logging of events of the specified *severity*.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, then it is reported in the cluster log.

Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

Category	Default threshold (All data nodes)
STARTUP	7
SHUTDOWN	7
STATISTICS	7
CHECKPOINT	7
NODERESTART	7
CONNECTION	7
ERROR	15
INFO	7

Thresholds are used to filter events within each category. For example, a `STARTUP` event with a priority of 3 is not logged unless the threshold for `STARTUP` is changed to 3 or lower. Only events with priority 3 or lower are sent if the threshold is 3.

Event severity levels are shown below. (**Note:** These correspond to UNIX `syslog` levels, except for `LOG_EMERG` and `LOG_NOTICE`, which are not used or mapped.)

1	ALERT	A condition that should be corrected immediately, such as a corrupted system database
2	CRITICAL	Critical conditions, such as device errors or insufficient resources
3	ERROR	Conditions that should be corrected, such as configuration errors
4	WARNING	Conditions that are not errors, but that might require handling
5	INFO	Informational messages
6	DEBUG	Debugging messages used for NDB Cluster development

Event severity levels can be turned on or off. If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

16.6.2.2. Log Events

An event report as reported in the event logs has the following format: *<datetime>* [*<string>*] *<severity>* -- *<message>*. For example:

```
09:19:30 2005-04-24 [NDB] INFO -- Node 4 Start phase 4 completed
```

All reportable events are discussed in this section, ordered by category and severity level within each category.

CONNECTION Events

These are events associated with connections between Cluster nodes.

Event	Priority	Severity Level	Description
DB nodes connected	8	INFO	Data nodes connected
DB nodes disconnected	8	INFO	Data nodes disconnected
Communication closed	8	INFO	SQL node or data node connection closed
Communication opened	8	INFO	SQL node or data node connection opened

CHECKPOINT Events

The logging messages shown below are associated with checkpoints.

(Note: GCP = Global Checkpoint, LCP = Local Checkpoint.)

Event	Priority	Severity Level	Description
LCP stopped in calc keep GCI	0	ALERT	LCP stopped
Local checkpoint fragment completed	11	INFO	LCP on a fragment has been completed
Global checkpoint completed	10	INFO	GCP finished
Global checkpoint started	9	INFO	Start of GCP: REDO log is written to disk
Local checkpoint completed	8	INFO	LCP completed normally
Local checkpoint started	7	INFO	Start of LCP: data written to disk
Report undo log blocked	7	INFO	UNDO logging blocked; buffer near overflow

STARTUP Events

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

Event	Priority	Severity Level	Description
Internal start signal received ST-TORRY	15	INFO	Blocks received after completion of restart
Undo records executed	15	INFO	
New REDO log started	10	INFO	GCI keep <i>X</i> , newest restorable GCI <i>Y</i>
New log started	10	INFO	Log part <i>X</i> , start MB <i>Y</i> , stop MB <i>Z</i>
Node has been refused to be included into the cluster	8	INFO	Node cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem

DB node neighbours	8	INFO	Shows neighbouring data nodes
DB node start phase <i>X</i> completed	4	INFO	A data node start phase has been completed
Node has been successfully included into the cluster	3	INFO	Displays the node, managing node, and dynamic ID
DB node start phases initiated	1	INFO	NDB Cluster nodes starting
DB node all start phases completed	1	INFO	NDB Cluster nodes started
DB node shutdown initiated	1	INFO	Shutdown of data node has commenced
DB node shutdown aborted	1	INFO	Unable to shut down data node normally

NODERESTART Events

The following events are generated when restarting a node and relate to the success or failure of the node restart process.

Event	Priority	Severity Level	Description
Node failure phase completed	8	ALERT	Reports completion of node failure phases
Node has failed, node state was <i>X</i>	8	ALERT	Reports that a node has failed
Report arbitrator results	2	ALERT	There are 8 different possible results for arbitration attempts: * Arbitration check failed - less than 1/2 nodes left * Arbitration check succeeded - node group majority * Arbitration check failed - missing node group * Network partitioning - arbitration required * Arbitration succeeded - affirmative response from node <i>X</i> * Arbitration failed - negative response from node <i>X</i> * Network partitioning - no arbitrator available * Network partitioning - no arbitrator configured
Completed copying a fragment	10	INFO	
Completed copying of dictionary information	8	INFO	
Completed copying distribution information	8	INFO	
Starting to copy fragments	8	INFO	
Completed copying all fragments	8	INFO	
GCP takeover started	7	INFO	
GCP takeover completed	7	INFO	
LCP takeover started	7	INFO	
LCP takeover completed (state = <i>X</i>)	7	INFO	
Report whether an arbitrator is found or not	6	INFO	There are 7 different possible outcomes when seeking an arbitrator: * Management server restarts arbitration thread [state= <i>X</i>] * Prepare arbitrator node <i>X</i> [ticket= <i>Y</i>] * Receive arbitrator node <i>X</i> [ticket= <i>Y</i>] * Started arbitrator node <i>X</i> [ticket= <i>Y</i>] * Lost arbitrator node <i>X</i> - process failure [state= <i>Y</i>] * Lost arbitrator node <i>X</i> - process exit [state= <i>Y</i>] * Lost arbitrator node <i>X</i> <error msg>[state= <i>Y</i>]

STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

Event	Priority	Severity Level	Description
Report job scheduling statistics	9	INFO	Mean internal job scheduling statistics
Sent number of bytes	9	INFO	Mean number of bytes sent to node <i>X</i>
Received # of bytes	9	INFO	Mean number of bytes received from node <i>X</i>
Report transaction statistics	8	INFO	Number of: transactions, commits, reads, simple reads, writes, concurrent operations, attribute info, aborts
Report operations	8	INFO	Number of operations
Report table create	7	INFO	
Memory usage	5	INFO	Data and index memory usage (80%, 90% and 100%)

ERROR Events

These events relate Cluster errors and warnings and generally indicate that a major malfunction or failure has occurred.

Event	Priority	Severity	Description
Dead due to missed heartbeat	8	ALERT	Node <i>X</i> declared dead due to missed heartbeat
Transporter errors	2	ERROR	
Transporter warnings	8	WARNING	
Missed heartbeats	8	WARNING	Node <i>X</i> missed heartbeat # <i>Y</i>
General warning events	2	WARNING	

INFO Events

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

Event	Priority	Severity	Description
Sent heartbeat	12	INFO	Heartbeat sent to node <i>X</i>
Create log bytes	11	INFO	Log part, log file, MB
General info events	2	INFO	

16.6.3. Single User Mode

Single user mode allows the database administrator to restrict access to the database system to a single MySQL server (SQL node). When entering single user mode all connections to all other MySQL servers are closed gracefully and all running transactions are aborted. No new transactions are allowed to be started.

Once the cluster has entered single user mode, only the designated SQL node is granted access to the database. You can use the **all status** command to see when the cluster has entered single user mode.

Example:

```
ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the SQL node whose node ID is **5** becomes the cluster's only permitted user.

The node specified in the command above must be a MySQL Server node; An attempt to specify any other type of node will be rejected.

Note: When the above command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command **EXIT SINGLE USER MODE** changes the state of the cluster's data nodes from single user mode to normal mode. MySQL Servers waiting for a connection (that is, for the cluster to become ready and available), are now allowed to connect. The MySQL Server denoted as the single-user SQL node continues to run (if it is connected), during and after the state change.

Example:

```
EXIT SINGLE USER MODE
```

The recommend way to a node failure when running in single user mode is to do either of the following:

- 1. Finish all single user mode transactions
 2. Issue the **EXIT SINGLE USER MODE** command
 3. Restart the cluster's data nodes

or

- Or restart database nodes prior to entering single user mode.

16.6.4. On-line Backup of MySQL Cluster

This section describes how to create a backup and how to restore the database from a backup at a later time.

16.6.4.1. Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata:** the names and definitions of all database tables.
- **Table records:** the data actually stored in the database tables at the time that the backup was made
- **Transaction log:** a sequential record telling how and when data was stored in the database

Each of these is saved on all nodes participating in the backup. During backup each node saves these three parts into three files on disk:

- `BACKUP-<BackupId>.<NodeId>.ctl`

A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- `BACKUP-<BackupId>-0.<NodeId>.data`

A data file containing the table records, which are saved on a per-fragment basis; that is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states to which tables the records belong. Following the list of records there is a footer containing a checksum for all records.

- `BACKUP-<BackupId>.<NodeId>.log`

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records, since different nodes host different database fragments.

In the table above, `<BackupId>` stands for the backup identifier and `<NodeId>` is the unique identifier for the node creating the file.

16.6.4.2. Using The Management Server to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 16.6.4.4, “Configuration for Cluster Backup”.)

To create a backup using the management server involves the following steps:

1. Start the management server (`ndb_mgm`).
2. Execute the command `START BACKUP`.
3. The management server will reply with a message ```Start of backup ordered''`. This means that the management server has submitted the request to the cluster, but has not yet received any response.
4. The management server will reply ```Backup <BackupId> started''`, where `<BackupId>` is the unique identifier for this particular backup. (This ID will also be saved in the cluster log, if it has not been configured otherwise.) This means that the cluster has received and processed the backup request. It does not mean that the backup has completed.
5. The management server will signal that the backup is finished with the message ```Backup <BackupId> completed''`.

To abort a backup already in progress:

1. Start the management server.
2. Execute the command `'ABORT BACKUP <BackupId>'`. The number `<BackupId>` is the identifier of the backup that was included in the response of the management server when the backup was started (in the message ```Backup <BackupId> started''`).
3. The management server will acknowledge the abort request with ```Abort of backup <BackupId> ordered''`; note that no actual response to this request has yet been received.

4. Once the the backup has been aborted, the management server will report ``Backup <BackupId> has been aborted for reason XYZ''. This means that the cluster has terminated the backup and that all files related to this backup have been removed from the cluster filesystem.

Note: If there is no backup with ID <BackupId> running when it is aborted, the management server will not make any explicit response. However, there will be a line in the cluster log indicating that an invalid abort command was sent.

16.6.4.3. How to Restore a Cluster Backup

The cluster restoration program is implemented as separate command line utility **ndb_restore**, which reads the files created by the backup and inserts the stored information into the database. The restore program must be executed once for each set of backup files, that is, as many times as there were database nodes running when the backup was created.

The first time you run the restoration program, you also need to restore the metadata; in other words, you must re-create the database tables. (Note that the cluster should have an empty database when starting to restore a backup.) The restore program acts as an API to the cluster and therefore requires a free connection in order to connect to the cluster. This can be verified with the **ndb_mgm** command **SHOW**. The switch **-c <connectstring>** may be used to locate the MGM node (see Section 16.4.4.2, “The MySQL Cluster *connectstring*” for information on connectstrings). The backup files must be present in the directory given as an argument to the restoration program.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID **12**, created in a cluster with two database nodes having the node IDs **2** and **3** is to be restored to a cluster with four nodes. Then **ndb_restore** must be run twice --- once for each database node in the cluster where the backup was taken.

Note: For rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. However, the data files must always be applied before the logs.

16.6.4.4. Configuration for Cluster Backup

There are four configuration parameters essential for backup:

- **BackupDataBufferSize**
Amount of memory used to buffer data before it is written to disk.
- **BackupLogBufferSize**
Amount of memory used to buffer log records before these are written to disk.
- **BackupMemory**
Total memory allocated in a database node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.
- **BackupWriteSize**
Size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in Section 16.4, “MySQL Cluster Configuration”.

16.6.4.5. Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or insufficient disk space. You should check that there is enough memory allocated for the backup. Also check that there is enough space on the hard drive partition of the backup target.

Currently (as of MySQL 4.1.10a) NDB does not support repeatable reads, which can cause problems with the restore process. While the backup process is "hot", restoring a MySQL Cluster from backup is not a 100% "hot" process. This is due to the fact that, for the duration of the restore process, running transactions get non-repeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

16.7. Using High-Speed Interconnects with MySQL Cluster

Even before design of NDB Cluster began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, NDB Cluster was designed from the very beginning to allow for different transporters.

Currently the code base includes 4 different transporters. Most users today employ TCP/IP over Ethernet since this ubiquitous. This is also by far the best-tested transporter in MySQL Cluster.

We are working to make sure that communication with the **ndbd** process is made in as large chunks as possible since this will benefit all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: either a custom transporter can be designed to handle this case, or one can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by Dolphin [<http://www.dolphinics.com/>].

16.7.1. Configuring MySQL Cluster to use SCI Sockets

In this section we will show how one can use a cluster configured for normal TCP/IP communication to use SCI Sockets instead. This documentation is based on SCI Sockets version 2.3.0 as of 1 October 2004.

Prerequisites

Any machines with which you wish to use SCI Sockets need to be equipped with SCI cards.

It is possible to use SCI Sockets with any version of MySQL Cluster. No special builds are needed since it uses normal socket calls which are already available in MySQL Cluster. However, SCI Sockets are currently supported only on Linux 2.4 and 2.6 kernels. SCI Transporters works on additional operating systems although we have verified these only with Linux 2.4 to date.

There are essentially four requirements for SCI Sockets. First, it is necessary to build the SCI Socket libraries. Second, the SCI Socket kernel libraries need to be installed. Third, one or two configuration files need to be installed. Finally, the SCI Socket kernel library needs to be enabled either for the entire machine or for the shell where the MySQL Cluster processes are started. This process needs to be repeated for each machine in the cluster where you plan to use SCI Sockets for inter-node communication.

Two packages need to be retrieved to get SCI Sockets working. The first of these builds the libraries on which SCI Sockets are built; the second contains the SCI Socket libraries themselves. Currently, these are available only in source code format. The latest versions of these packages at the time of this writing were `DIS_GPL_2_5_0_SEP_10_2004.tar.gz` and `SCI_SOCKET_2_3_0_OKT_01_2004.tar.gz`. You should be able to find them (or possibly newer versions) at <http://www.dolphinics.no/support/downloads.html>.

Package Installation

Once you have obtained the library packages, the next step is to unpack them into appropriate directories, with the SCI Sockets library unpacked into a directory below the DIS code. Next, you need to build the libraries. This example shows the commands used on Linux/x86 to perform this task:

```
shell> tar xzf DIS_GPL_2_5_0_SEP_10_2004.tar.gz
shell> cd DIS_GPL_2_5_0_SEP_10_2004/src/
shell> tar xzf ../../SCI_SOCKET_2_3_0_OKT_01_2004.tar.gz
shell> cd ../adm/bin/Linux_pkgs
shell> ./make_PSB_66_release
```

It is possible to build these libraries for some 64-bit processors. To build the libraries for Opteron CPUs using the 64-bit extensions, run **make_PSB_66_X86_64_release** rather than **make_PSB_66_release**; if the build is made on an Itanium machine, then you should use **make_PSB_66_IA64_release**. The X86-64 variant should work for Intel EM64T architectures but this has not yet (to our knowledge) been tested.

Once the build process is complete, the compiled libraries will be found in a zipped tar file with a name along the lines of DIS-*<operating-system>-time-date*. It is now time to install the package in the proper place. In this example we will place the installation in /opt/DIS. (**Note:** You will most likely need to run the following as the root user.)

```
shell> cp DIS_Linux_2.4.20-8_181004.tar.gz /opt/
shell> cd /opt
shell> tar xzf DIS_Linux_2.4.20-8_181004.tar.gz
shell> mv DIS_Linux_2.4.20-8_181004 DIS
```

Network Configuration

Now that all the libraries and binaries are in their proper place we need to ensure that the SCI cards have proper node IDs within the SCI address space.

It is also necessary to decide on the network structure before proceeding. There are three types of network structures which can be used in this context:

- A simple one-dimensional ring
- One or more SCI switches with one ring per switch port
- A two- or three-dimensional torus.

Each of these topologies has its own method for providing node IDs. We discuss each of them in brief.

A simple ring uses node IDs which are non-zero multiples of 4: 4, 8, 12,...

The next possibility uses SCI switches. An SCI switch has 8 ports, each of which can support a ring. It is necessary to make sure that that different rings use different node ID spaces. In a typical configuration, the first port uses node IDs below 64 (4 - 60), the next 64 node IDs (68 - 124) are assigned to the next port, and so on, with node IDs 452 - 508 being assigned to the eighth port.

Two- and three-dimensional torus network structures take into account where each node is located in each dimension, incrementing by 4 for each node in the first dimension, by 64 in the second dimension, and (where applicable) by 1024 in the third dimension. See Dolphin's Web site [<http://www.dolphinics.com/support/index.html>] for more thorough documentation.

In our testing we have used switches, although most large cluster installations use the 2-D/3-D torus structures. The advantage provided by switches is that, with dual SCI cards and dual switches, it is possible to build relatively easily a redundant network where the average failover time on the SCI network is on the order of 100 microseconds. This is supported by the SCI transporter in MySQL Cluster and is also under development for the SCI Socket implementation.

Failover for the 2-D/3-D torus is also possible but requires sending out new routing indexes to all nodes. However, this requires only 100 milliseconds or so to complete and should be acceptable for most high-availability cases.

By placing cluster data nodes properly within the switched architecture, it is possible to use 2 switches to build a structure whereby 16 computers can be interconnected and no single failure can hinder more than one computer. With 32 computers and 2 switches it is possible to configure the cluster in such a manner that no single failure can cause the loss of more than two nodes; in this case it is also possible to know which pair of nodes will be affected. Thus, by placing the two in separate node groups, it is possible to build a safe MySQL Cluster installation.

To set the node ID for an SCI card use the following command in the `/opt/DIS/sbin` directory. In this example `-c 1` refers to the number of the SCI card (this will always be 1 if there is only 1 card in the machine), `-a 0` refers to adapter 0; and `68` is the node ID:

```
shell> ./sciconfig -c 1 -a 0 -n 68
```

If you have multiple SCI cards in the same machine, you can determine which card has which slot by issuing the following command:

```
shell> ./sciconfig -c 1 -gsn
```

This will give you the SCI card's serial number. Then repeat this procedure for `-c 2` and so on, for each card in the machine. Once you have matched each card with a slot, you can set node IDs for all cards.

After installing the necessary libraries and binaries, and setting the SCI node IDs, the next step is to set up the mapping from hostnames (or IP addresses) to SCI node IDs. This is done in the SCI sockets configuration file, which should be saved as `/etc/sci/scisock.conf`. In this file, the SCI node ID will be mapped to the hostname or IP address to communicate with, through the proper SCI card. Here is a very simple example of such a configuration file:

```
#host          #nodeId
alpha          8
beta           12
192.168.10.20  16
```

It is also possible to limit this configuration so that it applies only to a subset of the available ports for these hosts. An additional configuration file `/etc/sci/scisock_opt.conf` can be used to accomplish this, as shown here:

```
#-key          -type      -values
EnablePortsByDefault  yes
EnablePort        tcp        2200
DisablePort       tcp        2201
EnablePortRange    tcp        2202 2219
DisablePortRange    tcp        2220 2231
```

Driver Installation

With the configuration files in place, the drivers can be installed. First, the the low-level drivers and then the SCI socket driver need to be installed:

```
shell> cd DIS/sbin/
shell> ./drv-install add PSB66
shell> ./scisocket-install add
```

If desired, the installation can be checked by invoking a script which verifies that all nodes in the SCI socket configuration files are accessible:

```
shell> cd /opt/DIS/sbin/  
shell> ./status.sh
```

If you discover an error and need to change the SCI socket configuration, it is necessary to use the **ksocketconfig** to accomplish this task:

```
shell> cd /opt/DIS/util  
shell> ./ksocketconfig -f
```

Testing the Setup

To make sure that SCI sockets are actually being used, you can use the test program **latency_bench**. Using this utility's server component, clients can connect to the server to test the latency of the connection; determining whether or not SCI is enabled should be fairly simple from observing the latency. (**Note:** Before using **latency_bench**, it is necessary to set the LD_PRELOAD environment variable as shown later in this section.)

To set up a server, use the following:

```
shell> cd /opt/DIS/bin/socket  
shell> ./latency_bench -server
```

To run a client, use **latency_bench** again, except this time with the `-client` option:

```
shell> cd /opt/DIS/bin/socket  
shell> ./latency_bench -client hostname_of_server
```

SCI socket configuration should now be complete and MySQL Cluster ready to use both SCI Sockets and the SCI transporter (see Section 16.4.4.10, “MySQL Cluster SCI Transport Connections”).

Starting the Cluster

The next step in the process is to start MySQL Cluster. To enable usage of SCI Sockets it is necessary to set the environment variable LD_PRELOAD before starting **ndbd**, **mysqld**, and **ndb_mgmd**. This variable should point to the kernel library for SCI Sockets.

To start **ndbd** in a bash shell, do the following:

```
bash-shell> export LD_PRELOAD=/opt/DIS/lib/libkscisock.so  
bash-shell> ndbd
```

In a tcsh environment the same thing can be accomplished with:

```
tcsh-shell> setenv LD_PRELOAD=/opt/DIS/lib/libkscisock.so  
tcsh-shell> ndbd
```

Note: MySQL Cluster can use only the kernel variant of SCI Sockets.

16.7.2. Understanding the Impact of Cluster Interconnects

The **ndbd** process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.

There are four access methods:

- **Primary key access**

This is the simple access of a record through its primary key. In the simplest case only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch then those accesses will share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, then additional TCP/IP messages need to be set up.

- **Unique key access**

Unique key accesses are similar to primary key accesses, except that a unique key accesses is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by **ndbd**. Such requests also benefit from batching.

- **Full table scan**

When no indexes exist for a lookup on a table, then a full scan of a table is performed. This is sent as a single request to the **ndbd** process, which then divides the table scan into a set of parallel scans on all cluster **ndbd** processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.

- **Range scan using ordered index**

When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). A special optimization is planned for future versions of MySQL Cluster whereby only one partition will be scanned instead of all partitions in parallel when all bound index attributes include all attributes in the partitioning key.

To check the base performance of these access methods we have developed a set of benchmarks. One such benchmark, **testReadPerf**, tests simple and batched primary and unique key accesses. This benchmark also measures the setup cost of range scans by issuing scans returning a single record. There is also a variant of this benchmark which uses a range scan to fetch a batch of records.

In this way, we can test the cost of single key access and single record scan accesses, and measure the impact of the communication media used, on base access methods.

In our tests, we ran the base benchmarks for both a normal transporter using TCP/IP sockets and a similar setup using SCI sockets. The figures reported below are for small accesses of 20 records per access. The difference between serial and batched access decreases by a factor of 3 to 4 when using 2 kB records instead. SCI Sockets were not tested with 2 kB records. Tests were performed on a cluster with 2 data nodes running on 2 dual-CPU machines equipped with AMD MP1900+ processors.

Access type:	TCP/IP sockets	SCI Socket
Serial pk access:	400 microseconds	160 microseconds
Batched pk access:	28 microseconds	22 microseconds
Serial uk access:	500 microseconds	250 microseconds
Batched uk access:	70 microseconds	36 microseconds
Indexed eq-bound:	1250 microseconds	750 microseconds
Index range:	24 microseconds	12 microseconds

We also performed another set of tests to check the performance of SCI Sockets vis-à-vis that of the SCI transporter, and both of these as compared with the TCP/IP transporter. All these tests used primary key accesses either serially and multi-threaded, or multi-threaded and batched.

The tests showed that SCI sockets were about 100% faster than TCP/IP. The SCI transporter was faster in most cases compared to SCI sockets. One notable case occurred with many threads in the test program, which showed that the SCI transporter did not perform very well when used for the **mysqld** process.

Our overall conclusion was that, for most benchmarks, using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case the CPU processing in the **ndbd** processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between **ndbd** processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the **ndbd** process since the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the **ndbd** process priority is set in such a way that the process does not lose priority due to running for an extended period of time, as can be done by locking processes to CPU's in Linux 2.6. If such a configuration is possible, then the **ndbd** process will benefit by 10-70% compared to using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. We have tested MySQL Cluster so far only with SCI sockets. We also include documentation above on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

16.8. Cluster Limitations in MySQL 4.1

In this section, we provide a listing of known limitations in MySQL Cluster releases in the 4.1.x series when compared to features available when using the MyISAM and InnoDB storage engines. Currently there are no plans to address these in coming releases of 4.1; however, we will attempt to supply fixes for these issues in MySQL 5.0 and subsequent releases. If you check the Cluster category in the MySQL bugs database at <http://bugs.mysql.com>, you can find known bugs which (if marked 4.1) we intend to correct in upcoming releases of MySQL 4.1.

- **Noncompliance in syntax** (resulting in errors when running existing applications):
 - Not all charsets and collations supported; see Section D.10.7, “MySQL Cluster-4.1.6 (10 Oct 2004)” for a list of those that are supported.
 - There are no prefix indexes; only entire fields can be indexed.
 - Text indexes are not supported.
 - Geometry datatypes (WKT and WKB) are not supported.
- **Non compliance in limits/behavior** (may result in errors when running existing applications):
 - There is no partial rollback of transactions. A duplicate key or similar error will result in a rollback of the entire transaction.
 - A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 16.4.4, “Configuration File”. Most configuration parameters can be upgraded online. These hard limits include:
 - Database memory size and index memory size (`DataMemory` and `IndexMemory`, respectively).
 - The maximum number of transactions that can be performed is set using the configuration parameter `MaxNoOfConcurrentOperations`. Note that bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.
 - Different limits related to tables and indexes. For example, the maximum number of ordered indexes per table is determined by `MaxNoOfOrderedIndexes`.

- Database names, table names and attribute names cannot be as long in NDB tables as with other table handlers. Attribute names are truncated to 31 characters, and if not unique after truncation give rise to errors. Database names and table names can total maximum of 122 characters. (That is, the maximum length for an NDB Cluster table name is 122 characters less the number of characters in the name of the database of which that table is a part.)
- In MySQL 4.1 and 5.0, all Cluster table rows are of fixed length. This means (for example) that if a table has one or more VARCHAR fields containing only relatively small values, more memory and disk space will be required when using the NDB storage engine than would be for the same table and data using the MyISAM engine. We are working to rectify this issue in MySQL 5.1.
- The maximum number of metadata objects is limited to 1600, including database tables, system tables, indexes and BLOBs. We are working to increase this to approximately 20k in MySQL 5.0.
- The maximum number of attributes per table is limited to 128.
- The maximum permitted size of any one row is 8k, not including data stored in BLOB columns. We expect to increase this to approximately 32k in MySQL 5.1.
- The maximum number of attributes per key is 32.
- **Unsupported features** (do not cause errors, but are not supported or enforced):
 - The foreign key construct is ignored, just as it is in MyISAM tables.
 - Savepoints and rollbacks to savepoints are ignored as in MyISAM.
- **Performance and limitation-related issues:**
 - The query cache is disabled, since it is not invalidated if an update occurs on a different MySQL server.
 - There are query performance issues due to sequential access to the NDB storage engine; it is also relatively more expensive to do many range scans than it is with either MyISAM or InnoDB.
 - The `Records in range` statistic is not supported, resulting in non-optimal query plans in some cases. Employ `USE INDEX` or `FORCE INDEX` as a workaround.
 - Unique hash indexes created with `USING HASH` cannot be used for accessing a table if `NULL` is given as part of the key.
- **Missing features:**
 - The only supported isolation level is `READ_COMMITTED`. (InnoDB supports `READ_COMMITTED`, `REPEATABLE_READ`, and `SERIALIZABLE`.) See MySQL Cluster Backup Troubleshooting for information on how this can effect backup/restore of Cluster databases.
 - No durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.
- **Problems relating to multiple MySQL servers** (not relating to MyISAM or InnoDB):
 - `ALTER TABLE` is not fully locking when running multiple MySQL servers (no distributed table lock).
 - MySQL replication will not work correctly off if updates are done on multiple MySQL servers. However, if the database partitioning scheme done at the application level, and no transactions take place across these partitions, then replication can be made to work.

- Autodiscovery of databases is not supported for multiple MySQL servers accessing the same MySQL Cluster. However, autodiscovery of tables is supported in such cases. What this means is that after a database named `db_name` is created or imported using one MySQL server, you should issue a `CREATE DATABASE db_name;` statement on each additional MySQL server that access the same MySQL Cluster. (As of MySQL 5.0.2 you may also use `CREATE SCHEMA db_name;`.) Once this has been done for a given MySQL server, that server should be able to detect the database tables without error.
- **Issues exclusive to MySQL Cluster** (not related to MyISAM or InnoDB):
 - All machines used in the cluster must have the same architecture; that is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.
 - It is not possible to make online schema changes such as those accomplished using `ALTER TABLE` or `CREATE INDEX`, as the NDB Cluster does not support autodiscovery of such changes. (However, you can import or create a table that uses a different storage engine, then convert it to NDB using `ALTER TABLE tbl_name ENGINE=NDBCLUSTER;`. In such a case, you will need to issue a `FLUSH TABLES` command to force the cluster to pick up the change.)
 - Online adding or dropping nodes is not possible (the cluster must be restarted in such cases).
 - When using multiple management servers one must give nodes explicit IDs in connectstrings since automatic allocation of node IDs does not work across multiple management servers.
 - When using multiple management servers one must take extreme care to have the same configurations for all management servers. No special checks for this are performed by the cluster.
 - The maximum number of data nodes is 48.
 - The total maximum number of nodes in a MySQL Cluster is 63. This number includes all MySQL Servers (SQL nodes), data nodes, and management servers.

This listing is intended to be complete with respect to the conditions set forth at the beginning of this section. You can report any discrepancies that you encounter to the MySQL bugs database at <http://bugs.mysql.com/>. If we do not plan to fix the problem in MySQL 4.1, we will add it to the list above.

16.9. MySQL Cluster in 5.0 and 5.1

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.0 as compared to MySQL 4.1. We will also discuss our roadmap for further improvements to MySQL Cluster as currently planned for MySQL 5.1.

In the past we have recommended that users of MySQL Cluster not use version 5.0 of MySQL since MySQL Cluster in the 5.0.x series wasn't yet fully tested. Beginning with the release of MySQL 5.0.3-beta the clustering functionality of MySQL 5.0 became comparable to that of MySQL 4.1. MySQL 4.1 is still recommended for production use at this time; however, MySQL 5.0 is of high quality as well, and we encourage you to begin testing with Cluster in MySQL 5.0 if you think that you are interested in using it once it enters production later in 2005. There are relatively few changes between the NDB Cluster storage engine implementations in MySQL 4.1 and in 5.0, so the upgrade path should be relatively quick and painless.

Since MySQL 5.0.3-beta was made available, nearly all significantly new features being developed for MySQL Cluster are going into the MySQL 5.1 tree. We also provide some hints about what Cluster in MySQL 5.1 is likely to include later in this section (see Section 16.9.2, "MySQL 5.1 De-

velopment Roadmap for MySQL Cluster”).

16.9.1. MySQL Cluster Changes in MySQL 5.0

MySQL 5.0.3-beta and later releases contain a number of new features that are likely to be of interest:

- **Push-Down Conditions:** A query such as

```
SELECT * FROM t1 WHERE non_indexed_attribute = 1;
```

will use a full table scan and the condition will be evaluated in the cluster's data nodes. Thus it is not necessary to send the records across the network for evaluation. (That is, function transport is used, rather than data transport.) For this type of query you should see a speed up factor of 5-10. Please note that this feature is currently disabled by default (pending more thorough testing), but it should work in most cases. This feature can be enabled through the use of the command `SET engine-condition-pushdown=On;` command. Alternatively, you can run `mysqld` with the this feature enabled by starting the MySQL server with the new `-engine-condition-pushdown` option flag.

You can use `EXPLAIN` to determine when push-down conditions are being used.

A major benefit of this change is that queries are now executed in parallel. This means that queries against non-indexed columns can run as much as 5 to 10 times, *times the number of data nodes*, faster than previously, since multiple CPUs can work on the query in parallel.

- **Decreased IndexMemory Usage:** In MySQL 5.0, each record consumes approximately 25 bytes of index memory, and every unique index uses 25 bytes per record of index memory (in addition to some data memory since these are stored in a separate table). This is because there is no storage of the primary key in the index memory anymore.
- **Query Cache Enabled for MySQL Cluster:** See Section 5.12, “The MySQL Query Cache” for information on configuring and using the query cache.
- **New Optimizations:** One optimization that merits particular attention is that a batched read interface is now used in some queries. For example, consider the following query:

```
SELECT * FROM t1 WHERE primary_key IN (1,2,3,4,5,6,7,8,9,10);
```

This query will be executed 2 to 3 times more quickly than in previous MySQL Cluster versions due to the fact that all 10 key lookups are sent in a single batch rather than one at a time.

- **Limit On Number of Metadata Objects:** In MySQL 4.1, each Cluster database may contain a maximum of 1600 metadata objects, including database tables, system tables, indexes and BLOBs. In MySQL 5.0, we expect to increase this number to 20,320. We hope to implement this enhancement in the MySQL 5.0.6 beta release in mid-2005.

16.9.2. MySQL 5.1 Development Roadmap for MySQL Cluster

What is said here is a status report based on recent commits to the MySQL 5.1 source tree. It should be noted all 5.1 development is subject to change.

There are currently 4 major new features being developed for MySQL 5.1:

- **Integration of MySQL Cluster into MySQL Replication:** This will make it possible to update from any MySQL Server in the cluster and still have the MySQL Replication handled by one of the MySQL Servers in the cluster and the installation on the slave side consistent.

- **Support for disk-based records:** Records on disk will be supported. Indexed fields including the primary key hash index must still be stored in RAM but all other fields can be on disk.
- **Variable sized records:** A column defined as `VARCHAR(255)` currently uses 260 bytes of storage independent of what is stored in any particular record. In MySQL 5.1 Cluster tables only the portion of the field actually taken up by the record will be stored. This will make possible a reduction in space requirements for such columns by a factor of 5 in many cases.
- **User-defined Partitioning:** Users will be able to define partitions based on the fields part of the primary key. The MySQL Server will be able to discover whether it is possible to prune away some of the partitions from the `WHERE` clause. Partitioning based on `KEY`, `HASH`, `RANGE`, and `LIST` handlers will be possible, as well as subpartitioning. This feature should also be available for many other handlers.

In addition, we are working to increase the 8k size limit for rows containing columns of types other than `BLOB` or `TEXT` in Cluster tables. This is due to the fact that rows are currently fixed in size and the page size is 32,768 bytes (minus 128 bytes for the row header). Currently this means that if we allowed more than 8k per record, any remaining space (up to approximately 14,000 bytes) would be left empty. In MySQL 5.1, we plan to fix this limitation so that using more than 8k in a given row does not result in the remainder of the page being wasted.

16.10. MySQL Cluster FAQ

- *What's the difference in using Cluster vs. using replication?*

In a replication setup, a master MySQL server updates one or more slaves. Transactions are committed sequentially, and a slow transaction can cause the slave to lag behind the master. This means that if the master fails, it is possible that the slave might not have recorded the last few transactions. If a transaction-safe engine such as InnoDB is being used, then a transaction will either be complete on the slave or not applied at all, but replication does not guarantee that all data on the master and the slave will be consistent at all times. In MySQL Cluster, all data nodes are kept in synch, and a transaction committed by any one data node is committed for all data nodes. In the event of a data node failure, all remaining data nodes will remain in a consistent state.

In short, whereas MySQL replication is asynchronous, MySQL Cluster is synchronous.

- *Do I need to do any special networking to run Cluster? (How do computers in a cluster communicate?)*

MySQL Cluster is intended to be used in a high-bandwidth environment, with computers connecting via TCP/IP. Its performance depends directly upon the connection speed between the cluster's computers. The minimum connectivity requirements for Cluster include a typical 100-megabit Ethernet network or the equivalent. We recommend you use gigabit Ethernet whenever available.

The faster SCI protocol is also supported, but requires special hardware. See MySQL Cluster Interconnects for more information about SCI.

- *How many computers do I need to run a cluster, and why?*

A minimum of three computers is required to run a viable cluster. However, the minimum **recommended** number of computers in a MySQL Cluster is four: one each to run the management and SQL nodes, and two computers to serve as storage nodes. The purpose of the two data nodes is to provide redundancy; the management node must run on a separate machine in order to guarantee continued arbitration services in the event that one of the data nodes fails.

- *What do the different computers do in a cluster?*

A MySQL Cluster has both a physical and logical organization, with computers being the phys-

ical elements. The logical or functional elements of a cluster are referred to as **nodes**, and a computer housing a cluster node is sometimes referred to as a **cluster host**. Ideally, there will be one node per cluster host, although it is possible to run multiple nodes on a single host. There are three types of nodes, each corresponding to a specific role within the cluster. These are:

1. **management node (MGM node)**: Provides management services for the cluster as a whole, including startup, shutdown, backups, and configuration data for the other nodes. The management node server is implemented as the application **ndb_mgmd**; the management client used to control MySQL Cluster via the MGM node is **ndb_mgm**.
2. **data node**: Stores and replicates data. Data node functionality is handled by an instance of the NDB data node process **ndbd**.
3. **SQL node**: This is simply an instance of MySQL Server (**mysqld**) started with the **-ndb-cluster** option.

- *With which operating systems can I use Cluster?*

As of MySQL 4.1.12, MySQL Cluster is officially supported on Linux, Mac OS X, and Solaris. We are working to add Cluster support for other platforms, including Windows (expected in MySQL 5.0), and our goal is eventually to offer MySQL Cluster on all platforms for which MySQL itself is supported.

It may be possible to run Cluster processes on other operating systems (including Windows), but Cluster on any but the three platforms mentioned here should be considered alpha software only and not for production use.

- *What are the hardware requirements for running MySQL Cluster?*

Cluster should run on any platform for which NDB-enabled binaries are available. Naturally, faster CPUs and more memory will improve performance, and 64-bit CPUs will likely be more effective than 32-bit processors. There must be sufficient memory on machines used for data nodes to hold each node's share of the database (see **How much RAM do I Need?** for more info). Nodes can communicate via a standard TCP/IP network and hardware. For SCI support, special networking hardware is required.

- *Since MySQL Cluster uses TCP/IP, does that mean I can run it over the Internet, with one or more nodes in a remote location?*

It is important to keep in mind that communications between the nodes in a MySQL Cluster are not secure; they are neither encrypted nor safeguarded by any other protective mechanism. The most secure configuration for a cluster is in a private network behind a firewall, with no direct access to any Cluster data or management nodes from outside.

It is very doubtful in any case that a cluster would perform reliably under such conditions, as MySQL Cluster was designed and implemented with the assumption that it would be run under conditions guaranteeing dedicated high-speed connectivity such as that found in a LAN setting using 100 Mbps or gigabit Ethernet. We neither test nor warrant its performance using anything slower than this.

- *Do I have to learn a new programming or query language to use Cluster?*

No. While some specialized commands are used to manage and configure the cluster itself, only standard (My)SQL queries and commands are required for:

- creating, altering, and dropping tables
- inserting, updating, and deleting table data
- creating, changing, and dropping primary and unique indexes
- configuring and managing SQL nodes (MySQL servers)

- *How do I find out what an error or warning message means when using Cluster?*

There are two ways in which this can be done:

1. From within the MySQL Monitor, use **SHOW ERRORS** or **SHOW WARNINGS** immediately upon being notified of the error or warning condition. These can also be displayed in MySQL Query Browser.
 2. From a system shell prompt, use **perror --ndb error-code**.
- *Is MySQL Cluster transaction-safe? What table types does Cluster support?*

Yes. MySQL Cluster is enabled for tables created with the NDB storage engine, which supports transactions. NDB is the only MySQL storage engine which supports clustering.

- *What does "NDB" mean?*

This stands for "Network Database".

- *Which version(s) of the MySQL software support Cluster? Do I have to compile from source?*

Cluster is supported in the MySQL-max binaries from version 4.1.3 onwards. You can determine whether or not your server binary has NDB support using either of the commands `SHOW VARIABLES LIKE 'have_%%';` or `SHOW ENGINES;`. (See Section 5.1.2, "The **mysqld-max** Extended MySQL Server" for more information.)

Linux users, please note that NDB is **not** included in the 4.1.x RPMs; you should use the binaries supplied as `.tar.gz` archives in the MySQL Downloads area [<http://dev.mysql.com/downloads/>] instead. You can also obtain NDB support by compiling the `-max` binaries from source, but it is not necessary to do so simply to use MySQL Cluster. Beginning with MySQL 5.0.4, there are separate RPM packages for the NDB storage engine and accompanying management and other tools; see the NDB RPM Downloads section of the MySQL 5.0 Downloads page for these.

- *How much RAM do I need? Is it possible to use disk memory at all?*

Currently, Cluster is in-memory only. This means that all table data (including indexes) is stored in RAM. Therefore, if your data takes up 1 gigabyte of space and you wish to replicate it once in the cluster, you'll need 2 gigabytes of memory to do so. This in addition to the memory required by the operating system and any applications running on the cluster computers.

You can use the following formula for obtaining a rough estimate of how much RAM is needed for each data node in the cluster:

$$(\text{SizeofDatabase} * \text{NumberOfReplicas} * 1.1) / \text{NumberOfDataNodes}$$

To calculate the memory requirements more exactly requires determining, for each table in the cluster database, the storage space required per row (see Section 11.5, "Column Type Storage Requirements" for details), and multiplying this by the number of rows. You must also remember to account for any column indexes as follows:

- In MySQL 4.1, each primary key or hash index created for an NDBCluster table requires 25 bytes storage, plus the size of the key, per record. In MySQL 5.0, this amount is reduced to 21-25 bytes per record. These indexes use `IndexMemory`.
- Each ordered index requires 10 bytes storage per record, using `DataMemory`.
- Creating a primary key or unique index also creates an ordered index, unless this index is created with `USING HASH`. In other words, if created without `USING HASH`, a primary key or unique index on a Cluster table will take up 35 bytes (plus the size of the key) per record in MySQL 4.1, and 31-35 bytes per record in MySQL 5.0.

Note that creating MySQL Cluster tables with `USING HASH` for all primary keys and unique indexes will generally cause table updates to run more quickly. This is due to the fact that less memory is required (since no ordered indexes are created), and that less CPU must be utilised (since fewer indexes must be read and possibly updated).

It is especially important to keep in mind that **every** MySQL Cluster table must have a primary key, that the NDB storage engine will create a primary key automatically if none is defined, and that this primary key is created without `USING HASH`.

As of MySQL 4.1.11/MySQL 5.0.4-beta there is no easy way determine exactly how much memory is being used for storage of Cluster indexes; however, warnings are written to the Cluster log when 80% of available DataMemory or IndexMemory is in use, and again when 85%, 90%, and so on is in use.

We often see questions from users who report that, when they're trying to populate a Cluster database, the loading process terminates prematurely and an error message like this one is observed:

```
ERROR 1114: The table 'my_cluster_table' is full
```

When this occurs, the cause is very likely to be that your setup does not provide sufficient RAM for all table data and all indexes, *including the primary key required by NDB*.

It is also worth noting that all data nodes should have the same amount of RAM, as no data node in a cluster can use more memory than the least amount available to any individual data node. In other words, if there are three computers hosting Cluster data nodes, with two of these having three gigabytes of RAM available to store Cluster data, and one having only one GB RAM, then each data node can devote only one GB to clustering.

- *In the event of a catastrophic failure --- say, for instance, the whole city lost power AND my UPS failed --- would I lose all my data?*

All committed transactions are logged. Therefore, while it is possible that some data could be lost in the event of a catastrophe, this should be quite limited. Data loss can be further reduced by minimising the number of operations per transaction.

- *Is it possible to use FULLTEXT indexes with Cluster?*

FULLTEXT indexing is not currently (MySQL 4.1.9) supported by the NDB storage engine. We are working to add this capability in a future release.

- *Can I run multiple nodes on a single computer?*

It is possible but not advisable. One of the chief reasons to run a cluster is to provide redundancy; in order to enjoy the full benefits of this redundancy, each node should reside on a separate machine. If you place multiple nodes on a single machine and that machine fails, you lose all of those nodes. Given that MySQL Cluster can be run on commodity hardware loaded with a low-cost or even no-cost operating system, it is well worth the expense of an extra machine or two in order to safeguard mission-critical data. It also worth noting that the requirements for a cluster host running a management node are minimal; this task can be accomplished with a 200 MHz Pentium CPU and sufficient RAM for the operating system plus a small amount of overhead for the `ndb_mgmd` and `ndb_mgm` processes.

- *Can I add nodes to a cluster without restarting it?*

Not at present. A simple restart is all that is required for adding new MGM or SQL nodes to a Cluster. When adding data nodes the process is more complex, and requires the following steps:

- Making a complete backup of all Cluster data
- Complete shutting down the cluster and all cluster node processes

- Restarting the cluster, using the **--initial** startup option
- Restoring all cluster data from the backup

In future, we hope to implement "hot" reconfiguration capability for MySQL Cluster in order to minimize (if not eliminate) requirements for restarting the cluster when adding new nodes.

- *Are there any limitations that I should be aware of when using Cluster?*

NDB tables in MySQL 4.1 are subject to the following limitations:

- Not all character sets and collations are supported. (For a complete listing of those that are supported, see Section D.10.7, "MySQL Cluster-4.1.6 (10 Oct 2004)").
- FULLTEXT indexes and prefix indexes are not supported. Only complete columns may be indexed.
- Chapter 18, *Spatial Extensions in MySQL* are not supported.
- Only complete rollbacks for transactions are supported. Partial rollbacks and rollbacks to save points are not supported.
- The maximum number of attributes allowed per table is 128, and attribute names cannot be any longer than 31 characters. For each table, the maximum combined length of the table and database names is 122 characters.
- The maximum size for a table row is 8 kilobytes, not counting BLOBs. There is no set limit for the number of rows per table; table size limits depend on a number of factors, in particular on the amount of RAM available to each data node.
- The NDB engine does not support foreign key constraints. As with MyISAM tables, these are ignored.
- Query caching is not supported.

We expect to lift many of these restrictions in MySQL 5.0. For additional information on current limitations, see Section 16.8, "Cluster Limitations in MySQL 4.1".

- *How do I import an existing MySQL database into a cluster?*

You can import databases into MySQL Cluster much as you would with any other version of MySQL. Other than the limitation mentioned in the previous question, the only other special requirement is that any tables to be included in the cluster must use the NDB storage engine. This means that the tables must be created with the option **ENGINE=NDB** or **ENGINE=NDBCLUSTER**.

- *How do cluster nodes communicate with one another?*

Cluster nodes can communicate via any of three different protocols: TCP/IP, SHM (shared memory), and SCI (Scalable Coherent Interface). Where available, SHM is used by default between nodes residing on the same cluster host. SCI is a high-speed (1 gigabit per second and higher), high-availability protocol used in building scalable multi-processor systems; it requires special hardware and drivers. See Section 16.7, "Using High-Speed Interconnects with MySQL Cluster" for more about using SCI as a transport mechanism in MySQL Cluster.

- *What is an arbitrator?*

If one or more nodes in a cluster fail, it is possible that not all cluster nodes will not be able to "see" one another. In fact, it is possible that two sets of nodes might become isolated from one another in a network partitioning, also known as a "split brain" scenario. This type of situation is undesirable because each set of nodes tries to behave as though it is the entire cluster.

When cluster nodes go down, there are two possibilities. If more than 50% of the remaining

nodes can communicate with each other, then we have what is sometimes called a "majority rules" situation, and this set of nodes is considered to be the cluster. The arbitrator comes into play when there is an even number of nodes: in such a case, the set of nodes to which the arbitrator belongs is considered to be the cluster, and nodes not belonging to this set are shut down.

The above is somewhat simplified; a more complete explanation taking into account node groups follows below:

When all nodes in at least one node group are alive, network partitioning is not an issue, because no one portion of the cluster can form a functional cluster. The real problem arises when no single node group has all its nodes alive, in which case network partitioning (the "split-brain" scenario) becomes possible. Then an arbitrator is required. All cluster nodes recognise the same node as the arbitrator, which is normally the management server; however, it is possible to configure any of the MySQL Servers in the cluster to act as the arbitrator instead. The arbitrator accepts the first set of cluster nodes to contact it, and tells the remaining set to die. Arbitrator selection is controlled by the `ArbitrationRank` configuration parameter for MySQL Server and management server nodes. (See Section 16.4.4.4, "Defining the MySQL Cluster Management Server" for details.) It should also be noted that the role of arbitrator does not in and of itself impose any heavy demands upon the host so designated, and thus the arbitrator host does not need to be particularly fast or to have extra memory especially for this purpose.

- *What column types are supported by MySQL Cluster?*

MySQL Cluster supports all of the usual MySQL column types, with the exception of those associated with MySQL's Chapter 18, *Spatial Extensions in MySQL*. In addition, there are some differences with regard to indexes when used with NDB tables. **Note:** In MySQL 4.1 and 5.0, Cluster tables (that is, tables created with `ENGINE=NDBCLUSTER`) have only fixed-width rows. This means that (for example) each record containing a `VARCHAR(255)` column will require 256 bytes of storage for that column, regardless of the size of the data stored therein. This issue is expected to be fixed in MySQL 5.1.

See Section 16.8, "Cluster Limitations in MySQL 4.1" for more information about these issues.

- *How do I start and stop MySQL Cluster?*

It is necessary to start each node in the cluster separately, in the following order:

1. Start the management node with the **`ndb_mgmd`** command.
2. Start each data node with the **`ndbd`** command.
3. Start each MySQL server (SQL node) using **`mysqld_safe --user=mysql &`**.

Each of these commands must be run from a shell on the machine housing the affected node. You can verify the the cluster is running by starting the MGM management client **`ndb_mgm`** on the machine housing the MGM node.

- *What happens to cluster data when the cluster is shut down?*

The data held in memory by the cluster's data nodes is written to disk, and is reloaded in memory the next time that the cluster is started.

To shut down the cluster, enter the following in a shell on the machine hosting the MGM node:

```
shell> ndb_mgm -e shutdown
```

This will cause the **`ndb_mgm`**, **`ndb_mgm`**, and any **`ndbd`** processes to terminate gracefully. MySQL servers running as Cluster SQL nodes can be stopped using **`mysqldadmin shutdown`**.

For more information, see Section 16.6.1, "Commands in the Management Client" and Section 16.3.6, "Safe Shutdown and Restart".

- *Is it helpful to have more than one management node for a cluster?*

It can be helpful as a fail-safe. Only one MGM node controls the cluster at any given time, but it is possible to configure one MGM as primary, and one or more additional management nodes to take over in the event that the primary MGM node fails.

- *Can I mix different kinds of hardware and operating systems in a Cluster?*

Yes, so long as all machines and operating systems are the same endian. It is also possible to use different MySQL Cluster releases on different nodes (for example, 4.1.8 on some nodes and 4.1.9 on others); however, we recommend this be done only as part of a rolling upgrade procedure.

- *Can I run two data nodes on a single host? Two SQL nodes?*

Yes, it is possible to do this. In the case of multiple `stdata` nodes, each node must use a different data directory. If you want to run multiple SQL nodes on one machine, then each instance of `mysqld` must use a different TCP/IP port.

- *Can I use hostnames with MySQL Cluster?*

Yes, it's possible to use DNS and DHCP for cluster hosts. However, if your application requires "five nines" availability, we recommend using fixed IP addresses. This is because making communication between Cluster hosts dependent on such services introduces additional points of failure, and the fewer of these, the better.

16.11. MySQL Cluster Glossary

The following terms are useful to an understanding of MySQL Cluster or have specialized meanings when used in relation to it.

- **Cluster:** In its generic sense, a cluster is a set of computers functioning as a unit and working together to accomplish a single task. **NDB Cluster** is the storage engine used by MySQL to implement data storage, retrieval, and management distributed amongst several computers. **MySQL Cluster** refers to a group of computers working together using the NDB engine to support a distributed MySQL database in a **shared-nothing architecture** using **in-memory storage**.
- **Configuration files:** Text files containing directives and information regarding the cluster, its hosts, and its nodes. These are read by the cluster's management nodes when the cluster is started. See Section 16.4.4, "Configuration File" for details.
- **Backup:** A complete copy of all cluster data, transactions and logs, saved to disk or other long-term storage.
- **Restore:** Returning the cluster to a previous state as stored in a backup.
- **Checkpoint:** Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to Cluster, it is a point in time where all committed transactions are stored on disk. With regard to the NDB storage engine, there are two sorts of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained:
 - **Local Checkpoint (LCP):** This is a checkpoint that is specific to a single node; however, LCP's take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.
 - **Global Checkpoint (GCP):** A GCP occurs every few seconds, when transactions for all nodes are synchronised and the redo-log is flushed to disk.
- **Cluster host:** A computer making up part of a MySQL Cluster. A cluster has both a *physical*

structure and a *logical* structure. Physically, the cluster consists of a number of computers, known as **cluster hosts** (or more simply as **hosts**). See also **Node, Node group**.

- **Node:** This refers to a logical or functional unit of MySQL Cluster, sometimes also referred to as a **cluster node**. In the context of MySQL Cluster, we use the term **node** to indicate a *process* rather than a physical component of the cluster. There are three node types required to implement a working MySQL Cluster. These are:
 - **Management (MGM) nodes:** Manages the other nodes within the MySQL Cluster. It provides configuration data to the other nodes; starts and stops nodes; handles network partitioning; creates backups and restores from them, and so forth.
 - **SQL (MySQL server) nodes:** Instances of MySQL Server which serve as front ends to data kept in the cluster's **data nodes**. Clients desiring to store, retrieve, or update data can access an SQL node just as they would any other MySQL Server, employing the usual authentication methods and API's; the underlying distribution of data between node groups is transparent to users and applications. SQL nodes access the cluster's databases as a whole without regard to the data's distribution across different data nodes or cluster hosts.
 - **Data nodes:** These nodes store the actual data. Table data fragments are stored in a set of node groups; each node group stores a different subset of the table data. Each of the nodes making up a node group stores a replica of the fragment for which that node group is responsible. Currently a single cluster can support up to 48 data nodes total.

It is possible for more than one node to co-exist on a single machine. (In fact, it is even possible to set up a complete cluster on one machine, although one would almost certainly not want to do this in a production environment.) It may be helpful to remember that, when working with MySQL Cluster, **host** refers to a physical component of the cluster whereas a **node** is a logical or functional component (that is, a process).

Note Regarding Obsolete Terms: In older versions of the MySQL Cluster documentation, data nodes were sometimes referred to as "Database nodes" or "DB nodes". In addition, SQL nodes were sometimes known as "client nodes" or "API nodes". This older terminology has been deprecated in order to minimize confusion, and for these reasons should be avoided.

- **Node group:** A set of data nodes. All data nodes in a node group contain the same data (fragments), and all nodes in a single group should reside on different hosts. It is possible to control which nodes belong to which node groups.
- **Node failure:** MySQL Cluster is not solely dependent upon the functioning of any single node making up the cluster; the cluster can continue to run if one or more nodes fail. The precise number of node failures that the cluster can tolerate depends upon the number of nodes and the cluster's configuration.
- **Node restart:** The process of restarting a failed cluster node.
- **Initial node restart:** The process of starting a cluster node with its filesystem removed. This is sometimes used in the course of software upgrades and in other special circumstances.
- **System crash (or system failure):** This can occur when so many cluster nodes have failed that the cluster's state can no longer be guaranteed.
- **System restart:** The process of restarting the cluster and reinitialising its state from disk logs and checkpoints. This is required after either a planned or an unplanned shutdown of the cluster.
- **Fragment:** A portion of a database table; in the NDB storage engine, a table is broken up into and stored as a number of fragments. A fragment is sometimes also called a **partition**; however, "fragment" is the preferred term. Tables are fragmented in MySQL Cluster in order to facilitate load balancing between machines and nodes.
- **Replica:** Under the NDB storage engine, each table fragment has number of replicas stored on other data nodes in order to provide redundancy. Currently there may be up to 4 replicas per fragment.

- **Transporter:** A protocol providing data transfer between nodes. MySQL Cluster currently supports 4 different types of transporter connections: **TCP/IP** (local), TCP/IP (remote), **SCI**, and **SHM** (experimental in MySQL 4.1).
 - **TCP/IP** is, of course, the familiar network protocol that underlies HTTP, FTP, etc., on the Internet.
 - **SCI (Scalable Coherent Interface)** is a high-speed protocol used in building multiprocessor systems and parallel-processing applications. Use of SCI with MySQL Cluster requires specialized hardware and is discussed in Section 16.7.1, “Configuring MySQL Cluster to use SCI Sockets”. For a basic introduction to SCI, see this essay at [dolphinics.com](http://www.dolphinics.com) [<http://www.dolphinics.com/corporate/scitech.html>].
 - **SHM** stands for Unix-style **shared memory** segments. Where supported, SHM is used automatically to connect nodes running on the same host. This is experimental in MySQL 4.1, but we intend to enable it fully in MySQL 5.0. The Unix man page for `shmop(2)` [<http://www.scit.wlv.ac.uk/cgi-bin/mansec?2+shmop>] is a good place to begin obtaining additional information about this topic.

Note: The cluster transporter is internal to the cluster. Applications using MySQL Cluster communicate with SQL nodes just as they do with any other version of MySQL Server (via TCP/IP or Windows named pipes/Unix sockets). Queries can be sent and results retrieved using the standard APIs.

- **NDB:** Refers to the storage engine used to enable MySQL Cluster. The NDB storage engine supports all the usual MySQL column types and SQL statements, and is ACID-compliant. This engine also provides full support for transactions (commits and rollbacks). "NDB" stands for **Network Database**.
- **Share-nothing architecture:** The ideal architecture for a MySQL Cluster. In a true share-nothing setup, each node runs on a separate host. The advantage such an arrangement is that there no single host or node can act as single point of failure or as a performance bottle neck for the system as a whole.
- **In-memory storage:** All data stored in each data node is kept in memory on the node's host computer. For each data node in the cluster, you must have available an amount of RAM equal to the size of the database times the number of replicas, divided by the number of data nodes. Thus, if the database takes up 1 gigabyte of memory, and you wish to set up the cluster with 4 replicas and 8 data nodes, a minimum of 500 MB memory will be required per node. Note that this is in addition to any requirements for the operating system and any applications running on the host.
- **Table:** As is usual in the context of a relational database, the term "table" denotes an ordered set of identically structured records. In MySQL Cluster, a database table is stored in a data node as a set of fragments, each of which is replicated on additional data nodes. The set of data nodes replicating the same fragment or set of fragments is referred to as a **node group**.
- **Cluster programs:** These are command-line programs used in running, configuring and administering MySQL Cluster. They include both server daemons:
 - `ndbd`: The data node daemon (runs a data node process)
 - `ndb_mgmd`: The management server daemon (runs a management server process)and client programs:
 - `ndb_mgm`: The management client (provides an interface for executing management commands)
 - `ndb_waiter`: Used to verify status of all nodes in a cluster
 - `ndb_restore`: Restores cluster data from backup

For more about these programs and their uses, see Section 16.5, “Process Management in MySQL Cluster”.

- **Event log:** MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, etc.), priority, and severity. A complete listing of all reportable events may be found in Section 16.6.2, “Event Reports Generated in MySQL Cluster”. Event logs are of two types:
 - **Cluster log:** Keeps a record of all desired reportable events for the cluster as a whole.
 - **Node log:** A separate log is also kept for each individual node.

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

Chapter 17. Introduction to MaxDB

MaxDB is an enterprise-level database. MaxDB is the new name of a database management system formerly called SAP DB.

17.1. History of MaxDB

The history of SAP DB goes back to the early 1980s when it was developed as a commercial product (Adabas). The database has changed names several times since then. When SAP AG, a company based in Walldorf, Germany, took over the development of that database system, it was called SAP DB.

SAP developed that database system to serve as a storage system for all heavy-duty SAP applications, namely R/3. SAP DB was meant to provide an alternative to third-party database systems such as Oracle, Microsoft SQL Server, and DB2 by IBM. In October 2000, SAP AG released SAP DB under the GNU GPL license (see Appendix H, *GNU General Public License*), thus making it Open Source software. In October 2003, more than 2,000 customers of SAP AG were using SAP DB as their main database system, and more than another 2,000 customers were using it as a separate database system besides their main database, as part of the APO/LiveCache solution.

In May 2003, a technology partnership was formed between MySQL AB and SAP AG. That partnership entitles MySQL AB to further develop SAP DB, rename it, and sell commercial licenses of the renamed SAP DB to customers who do not want to be bound to the restrictions imposed on them when using that database system under the GNU GPL (see Appendix H, *GNU General Public License*). In August 2003, SAP DB was renamed MaxDB by MySQL AB.

17.2. Licensing and Support

MaxDB can be used under the same licenses available for the other products distributed by MySQL AB. Thus, MaxDB is available under the GNU General Public License, and a commercial license. For more information on licensing, see <http://www.mysql.com/company/legal/licensing/>.

MySQL offers MaxDB support to non-SAP customers.

The first rebranded version was MaxDB 7.5.00, which was released in November 2003.

17.3. MaxDB-Related Links

The main page for information about MaxDB is <http://www.mysql.com/products/maxdb>. Information formerly available at <http://www.sapdb.org> has been moved there.

17.4. Basic Concepts of MaxDB

MaxDB operates as a client/server product. It was developed to meet the demands of installations processing a high volume of online transactions. Both online backup and expansion of the database are supported. Microsoft Clustered Server is supported directly for multiple server implementations; other failover solutions must be scripted manually. Database management tools are provided in both Windows and browser-based implementations.

17.5. Feature Differences Between MaxDB and MySQL

The following list provides a short summary of the main differences between MaxDB and MySQL; it is not complete.

- MaxDB runs as a client/server system. MySQL can run as a client/server system or as an embedded system.
- MaxDB might not run on all platforms supported by MySQL. For example, MaxDB does not run on IBM's OS/2.
- MaxDB uses a proprietary network protocol for client/server communication. MySQL uses either TCP/IP (with or without SSL encryption), sockets (under Unix-like systems), or named pipes (under Windows NT-family systems).
- MaxDB supports stored procedures. For MySQL, stored procedures are implemented in version 5.0. MaxDB also supports programming of triggers through an SQL extension, which is scheduled for MySQL 5.1. MaxDB contains a debugger for stored procedure languages, can cascade nested triggers, and supports multiple triggers per action and row.
- MaxDB is distributed with user interfaces that are text-based, graphical, or Web-based. MySQL is distributed with text-based user interfaces only; graphical user interface (MySQL Control Center, MySQL Administrator) are shipped separately from the main distributions. Web-based user interfaces for MySQL are offered by third parties.
- MaxDB supports a number of programming interfaces that also are supported by MySQL. However, MaxDB does not support RDO, ADO, or .NET, all of which are supported by MySQL. MaxDB supports embedded SQL only with C/C++.
- MaxDB includes administrative features that MySQL does not have: job scheduling by time, event, and alert, and sending messages to a database administrator on alert thresholds.

17.6. Interoperability Features Between MaxDB and MySQL

As part of MaxDB 7.6, the MaxDB Synchronization Manager is released. The Synchronization Manager supports creation of asynchronous replication scenarios between several MaxDB instances. However, interoperability features also are planned, so that the Synchronization Manager supports replication to and from a MySQL server.

In the first release, the Synchronization Manager supports inserting data into MySQL. This means that initially only replication from MaxDB to MySQL is supported. In the course of 2005, exporting of data from a MySQL server to the Synchronization Manager will be added, thus adding support for MySQL to MaxDB replication scenarios.

MaxDB 7.6, with the Synchronization Manager, was released as a beta version in January 2005. The production release is planned for April 2005.

17.7. Reserved Words in MaxDB

Like MySQL, MaxDB has a number of reserved words that have special meanings. Normally, they cannot be used as names of identifiers, such as database or table names. The following table lists reserved words in MaxDB, indicates the context in which those words are used, and indicates whether or not they have counterparts in MySQL. If such a counterpart exists, the meaning in MySQL might be identical or differing in some aspects. The main purpose is to list in which respects MaxDB differs from MySQL; therefore, this list is not complete.

For the list of reserved words in MySQL, see Section 9.6, "Treatment of Reserved Words in MySQL".

Reserved MaxDB	in	Context of usage in MaxDB	in	MySQL counterpart
@		Can prefix identifier, like ``@table"		Not allowed

ADDDATE ()	SQL function	ADDDATE () ; new in MySQL 4.1.1
ADDTIME ()	SQL function	ADDTIME () ; new in MySQL 4.1.1
ALPHA	SQL function	Nothing comparable
ARRAY	Data type	Not implemented
ASCII ()	SQL function	ASCII () , but implemented with a different meaning
AUTOCOMMIT	Transactions; ON by default	Transactions; OFF by default
BOOLEAN	Column types; BOOLEAN accepts as values only TRUE, FALSE, and NULL	BOOLEAN was added in MySQL 4.1.0; it is a synonym for BOOL which is mapped to TINYINT (1) . It accepts integer values in the same range as TINYINT as well as NULL. TRUE and FALSE can be used as aliases for 1 and 0.
CHECK	CHECK TABLE	CHECK TABLE; similar, but not identical usage
COLUMN	Column types	COLUMN; noise word
CHAR ()	SQL function	CHAR () ; identical syntax; similar, not identical usage
COMMIT	Implicit commits of transactions happen when data definition statements are issued	Implicit commits of transactions happen when data definition statements are issued, and also with a number of other statements
COSH ()	SQL function	Nothing comparable
COT ()	SQL function	COT () ; identical syntax and implementation
CREATE	SQL, data definition language	CREATE
DATABASE	SQL function	DATABASE () ; DATABASE is used in a different context; for example, CREATE DATABASE
DATE ()	SQL function	CURRENT_DATE
DATEDIFF ()	SQL function	DATEDIFF () ; new in MySQL 4.1.1
DAY ()	SQL function	Nothing comparable
DAYOFWEEK ()	SQL function	DAYOFWEEK () ; by default, 1 represents Monday in MaxDB and Sunday in MySQL
DISTINCT	SQL functions AVG, MAX, MIN, SUM	DISTINCT; but used in a different context: SELECT DISTINCT
DROP	DROP INDEX, for example	DROP INDEX; similar, but not identical usage
EBCDIC ()	SQL function	Nothing comparable
EXPAND ()	SQL function	Nothing comparable
EXPLAIN	Optimization	EXPLAIN; similar, but not identical usage
FIXED ()	SQL function	Nothing comparable
FLOAT ()	SQL function	Nothing comparable
HEX ()	SQL function	HEX () ; similar, but not identical usage
INDEX ()	SQL function	INSTR () or LOCATE () ; similar, but not identical syntaxes and meanings
INDEX	USE INDEX, IGNORE INDEX and similar hints are used right after SELECT; for example, SELECT ... USE INDEX	USE INDEX, IGNORE INDEX and similar hints are used in the FROM clause of a SELECT query; for example, in SELECT ... FROM ... USE INDEX
INITCAP ()	SQL function	Nothing comparable
LENGTH ()	SQL function	LENGTH () ; identical syntax, but slightly different implementation

LFILL ()	SQL function	Nothing comparable
LIKE	Comparisons	LIKE; but the extended LIKE MaxDB provides rather resembles the MySQL REGEX
LIKE wildcards	MaxDB supports ``%``, ``_``, ``Control-underline``, ``Control-up arrow``, ``*``, and ``?`` as wildcards in LIKE comparisons	MySQL supports ``%``, and ``_`` as wildcards in LIKE comparisons
LPAD ()	SQL function	LPAD () ; slightly different implementation
LTRIM ()	SQL function	LTRIM () ; slightly different implementation
MAKEDATE ()	SQL function	MAKEDATE () ; new in MySQL 4.1.1
MAKETIME ()	SQL function	MAKETIME () ; new in MySQL 4.1.1
MAPCHAR ()	SQL function	Nothing comparable
MICRO-SECOND ()	SQL function	MICROSECOND () ; new in MySQL 4.1.1
NOROUND ()	SQL function	Nothing comparable
NULL	Column types; comparisons	NULL; MaxDB supports special NULL values that are returned by arithmetic operations that lead to an overflow or a division by zero; MySQL does not support such special values
PI	SQL function	PI () ; identical syntax and implementation, but parentheses are mandatory in MySQL
REF	Data type	Nothing comparable
RFILL ()	SQL function	Nothing comparable
ROWNO	Predicate in WHERE clause	Similar to LIMIT clause
RPAD ()	SQL function	RPAD () ; slightly different implementation
RTRIM ()	SQL function	RTRIM () ; slightly different implementation
SEQUENCE	CREATE SEQUENCE, DROP SEQUENCE	AUTO_INCREMENT; similar concept, but different implementation
SINH ()	SQL function	Nothing comparable
SOUNDS ()	SQL function	SOUNDEX () ; slightly different syntax
STATISTICS	UPDATE STATISTICS	ANALYZE TABLE; similar concept, but different implementation
SUBSTR ()	SQL function	SUBSTRING () ; slightly different implementation
SUBTIME ()	SQL function	SUBTIME () ; new in MySQL 4.1.1
SYNONYM	Data definition language: CREATE [PUBLIC] SYNONYM, RENAME SYNONYM, DROP SYNONYM	Nothing comparable
TANH ()	SQL function	Nothing comparable
TIME ()	SQL function	CURRENT_TIME
TIMEDIFF ()	SQL function	TIMEDIFF () ; new in MySQL 4.1.1
TIMESTAMP ()	SQL function	TIMESTAMP () ; new in MySQL 4.1.1
TIMESTAMP () as argument to DAYOFMONTH () and DAY-OFYEAR ()	SQL function	Nothing comparable
TIMEZONE ()	SQL function	Nothing comparable

TRANSACTION ()	Returns the ID of the current transaction	Nothing comparable
TRANSLATE ()	SQL function	REPLACE () ; identical syntax and implementation
TRIM ()	SQL function	TRIM () ; slightly different implementation
TRUNC ()	SQL function	TRUNCATE () ; slightly different syntax and implementation
USE	Switches to a new database instance; terminates the connection to the current database instance; all subsequent commands are referred to this database instance	USE; identical syntax, but does not terminate the connection to the current database
USER	SQL function	USER () ; identical syntax, but slightly different implementation, and parentheses are mandatory in MySQL
UTC_DIFF ()	SQL function	UTC_DATE () ; provides a means to calculate the same result as UTC_DIFF ()
VALUE ()	SQL function, alias for COALESCE ()	COALESCE () ; identical syntax and implementation
VARIANCE ()	SQL function	VARIANCE () ; new in MySQL 4.1.0
WEEKOFYEAR ()	SQL function	WEEKOFYEAR () ; new in MySQL 4.1.1

Chapter 18. Spatial Extensions in MySQL

MySQL 4.1 introduces spatial extensions to allow the generation, storage, and analysis of geographic features. Currently, these features are available for MyISAM tables only.

This chapter covers the following topics:

- The basis of these spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data
- MySQL differences from the OpenGIS specification

18.1. Introduction

MySQL implements spatial extensions following the specification of the Open GIS Consortium (OGC). This is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data. The OGC maintains a Web site at <http://www.opengis.org/>.

In 1997, the Open GIS Consortium published the *OpenGIS (R) Simple Features Specifications For SQL*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the Open GIS Web site at <http://www.opengis.org/docs/99-049.pdf>. It contains additional information relevant to this chapter.

MySQL implements a subset of the **SQL with Geometry Types** environment proposed by OGC. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specifications describe a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

A **geographic feature** is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, a postcode area, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

You can also find documents that use the term **geospatial feature** to refer to geographic features.

Geometry is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

This chapter uses all of these terms synonymously: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. The term most commonly used here is **geometry**.

Let's define a **geometry** as *a point or an aggregate of points representing anything in the world that has a location.*

18.2. The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a Spatial Reference System, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

18.2.1. The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- `Geometry` (non-instantiable)
 - `Point` (instantiable)
 - `Curve` (non-instantiable)
 - `LineString` (instantiable)
 - `Line`
 - `LinearRing`
 - `Surface` (non-instantiable)
 - `Polygon` (instantiable)
 - `GeometryCollection` (instantiable)
 - `MultiPoint` (instantiable)
 - `MultiCurve` (non-instantiable)
 - `MultiLineString` (instantiable)
 - `MultiSurface` (non-instantiable)
 - `MultiPolygon` (instantiable)

It is not possible to create objects in non-instantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

`Geometry` is the base class. It's an abstract class. The instantiable subclasses of `Geometry` are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base `Geometry` class has subclasses for `Point`, `Curve`, `Surface`, and `GeometryCollection`:

- `Point` represents zero-dimensional objects.
- `Curve` represents one-dimensional objects, and has subclass `LineString`, with subclasses `Line` and `LinearRing`.

- `Surface` is designed for two-dimensional objects and has subclass `Polygon`.
- `GeometryCollection` has specialized zero-, one-, and two-dimensional collection classes named `MultiPoint`, `MultiLineString`, and `MultiPolygon` for modeling geometries corresponding to collections of `Points`, `LineStrings`, and `Polygons`, respectively. `MultiCurve` and `MultiSurface` are introduced as abstract superclasses that generalize the collection interfaces to handle `Curves` and `Surfaces`.

`Geometry`, `Curve`, `Surface`, `MultiCurve`, and `MultiSurface` are defined as non-instantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

`Point`, `LineString`, `Polygon`, `GeometryCollection`, `MultiPoint`, `MultiLineString`, and `MultiPolygon` are instantiable classes.

18.2.2. Class Geometry

`Geometry` is the root class of the hierarchy. It is a non-instantiable class but has a number of properties that are common to all geometry values created from any of the `Geometry` subclasses. These properties are described in the following list. (Particular subclasses have their own specific properties, described later.)

Geometry Properties

A geometry value has the following properties:

- Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.
- Its **SRID**, or Spatial Reference Identifier. This value identifies the geometry's associated Spatial Reference System that describes the coordinate space in which the geometry object is defined.

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

- Its **coordinates** in its Spatial Reference System, represented as double-precision (eight-byte) numbers. All non-empty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geocentric** system (coordinates on the Earth's surface) are different things.

- Its **interior**, **boundary**, and **exterior**.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its **MBR** (Minimum Bounding Rectangle), or Envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- Whether the value is **simple** or **non-simple**. Geometry values of types (`LineString`, `MultiPoint`, `MultiLineString`) are either simple or non-simple. Each type determines its own assertions for being simple or non-simple.
- Whether the value is **closed** or **not closed**. Geometry values of types (`LineString`, `MultiString`) are either closed or not closed. Each type determines its own assertions for be-

ing closed or not closed.

- Whether the value is **empty** or **non-empty** A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a `NULL` value). An empty geometry is defined to be always simple and has an area of 0.
- Its **dimension**. A geometry can have a dimension of #1, 0, 1, or 2:
 - #1 for an empty geometry.
 - 0 for a geometry with no length and no area.
 - 1 for a geometry with non-zero length and zero area.
 - 2 for a geometry with non-zero area.

Point objects have a dimension of zero. `LineString` objects have a dimension of 1. `Polygon` objects have a dimension of 2. The dimensions of `MultiPoint`, `MultiLineString`, and `MultiPolygon` objects are the same as the dimensions of the elements they consist of.

18.2.3. Class Point

A `Point` is a geometry that represents a single location in coordinate space.

Point Examples

- Imagine a large-scale map of the world with many cities. A `Point` object could represent each city.
- On a city map, a `Point` object could represent a bus stop.

Point Properties

- X-coordinate value.
- Y-coordinate value.
- `Point` is defined as a zero-dimensional geometry.
- The boundary of a `Point` is the empty set.

18.2.4. Class Curve

A `Curve` is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of `Curve` define the type of interpolation between points. `Curve` is a non-instantiable class.

Curve Properties

- A `Curve` has the coordinates of its points.
- A `Curve` is defined as a one-dimensional geometry.
- A `Curve` is simple if it does not pass through the same point twice.
- A `Curve` is closed if its start point is equal to its end point.

- The boundary of a closed `Curve` is empty.
- The boundary of a non-closed `Curve` consists of its two end points.
- A `Curve` that is simple and closed is a `LinearRing`.

18.2.5. Class `LineString`

A `LineString` is a `Curve` with linear interpolation between points.

LineString Examples

- On a world map, `LineString` objects could represent rivers.
- In a city map, `LineString` objects could represent streets.

LineString Properties

- A `LineString` has coordinates of segments, defined by each consecutive pair of points.
- A `LineString` is a `Line` if it consists of exactly two points.
- A `LineString` is a `LinearRing` if it is both closed and simple.

18.2.6. Class `Surface`

A `Surface` is a two-dimensional geometry. It is a non-instantiable class. Its only instantiable subclass is `Polygon`.

Surface Properties

- A `Surface` is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple `Surface` as a geometry that consists of a single "patch" that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple `Surface` is the set of closed curves corresponding to its exterior and interior boundaries.

18.2.7. Class `Polygon`

A `Polygon` is a planar `Surface` representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the `Polygon`.

Polygon Examples

- On a region map, `Polygon` objects could represent forests, districts, and so on.

Polygon Assertions

- The boundary of a `Polygon` consists of a set of `LinearRing` objects (that is, `LineString` objects that are both simple and closed) that make up its exterior and interior boundaries.

- A `Polygon` has no rings that cross. The rings in the boundary of a `Polygon` may intersect at a `Point`, but only as a tangent.
- A `Polygon` has no lines, spikes, or punctures.
- A `Polygon` has an interior that is a connected point set.
- A `Polygon` may have holes. The exterior of a `Polygon` with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a `Polygon` a simple geometry.

18.2.8. Class `GeometryCollection`

A `GeometryCollection` is a geometry that is a collection of one or more geometries of any class.

All the elements in a `GeometryCollection` must be in the same Spatial Reference System (that is, in the same coordinate system). There are no other constraints on the elements of a `GeometryCollection`, although the subclasses of `GeometryCollection` described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a `MultiPoint` may contain only `Point` elements)
- Dimension
- Constraints on the degree of spatial overlap between elements

18.2.9. Class `MultiPoint`

A `MultiPoint` is a geometry collection composed of `Point` elements. The points are not connected or ordered in any way.

MultiPoint Examples

- On a world map, a `MultiPoint` could represent a chain of small islands.
- On a city map, a `MultiPoint` could represent the outlets for a ticket office.

MultiPoint Properties

- A `MultiPoint` is a zero-dimensional geometry.
- A `MultiPoint` is simple if no two of its `Point` values are equal (have identical coordinate values).
- The boundary of a `MultiPoint` is the empty set.

18.2.10. Class `MultiCurve`

A `MultiCurve` is a geometry collection composed of `Curve` elements. `MultiCurve` is a non-instantiable class.

MultiCurve Properties

- A `MultiCurve` is a one-dimensional geometry.
- A `MultiCurve` is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
- A `MultiCurve` boundary is obtained by applying the "mod 2 union rule" (also known as the "odd-even rule"): A point is in the boundary of a `MultiCurve` if it is in the boundaries of an odd number of `MultiCurve` elements.
- A `MultiCurve` is closed if all of its elements are closed.
- The boundary of a closed `MultiCurve` is always empty.

18.2.11. Class `MultiLineString`

A `MultiLineString` is a `MultiCurve` geometry collection composed of `LineString` elements.

`MultiLineString` Examples

- On a region map, a `MultiLineString` could represent a river system or a highway system.

18.2.12. Class `MultiSurface`

A `MultiSurface` is a geometry collection composed of surface elements. `MultiSurface` is a non-instantiable class. Its only instantiable subclass is `MultiPolygon`.

`MultiSurface` Assertions

- Two `MultiSurface` surfaces have no interiors that intersect.
- Two `MultiSurface` elements have boundaries that intersect at most at a finite number of points.

18.2.13. Class `MultiPolygon`

A `MultiPolygon` is a `MultiSurface` object composed of `Polygon` elements.

`MultiPolygon` Examples

- On a region map, a `MultiPolygon` could represent a system of lakes.

`MultiPolygon` Assertions

- A `MultiPolygon` has no two `Polygon` elements with interiors that intersect.
- A `MultiPolygon` has no two `Polygon` elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
- A `MultiPolygon` may not have cut lines, spikes, or punctures. A `MultiPolygon` is a regular, closed point set.
- A `MultiPolygon` that has more than one `Polygon` has an interior that is not connected. The number of connected components of the interior of a `MultiPolygon` is equal to the number of

Polygon values in the `MultiPolygon`.

MultiPolygon Properties

- A `MultiPolygon` is a two-dimensional geometry.
- A `MultiPolygon` boundary is a set of closed curves (`LineString` values) corresponding to the boundaries of its `Polygon` elements.
- Each `Curve` in the boundary of the `MultiPolygon` is in the boundary of exactly one `Polygon` element.
- Every `Curve` in the boundary of an `Polygon` element is in the boundary of the `MultiPolygon`.

18.3. Supported Spatial Data Formats

This section describes the standard spatial data formats that are used to represent geometry objects in queries. They are:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format.

18.3.1. Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of Geometry is designed to exchange geometry data in ASCII form.

Examples of WKT representations of geometry objects are:

- A `Point`:
`POINT(15 20)`

Note that point coordinates are specified with no separating comma.

- A `LineString` with four points:
`LINestring(0 0, 10 10, 20 25, 50 60)`

Note that point coordinate pairs are separated by commas.

- A `Polygon` with one exterior ring and one interior ring:
`POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))`
- A `MultiPoint` with three `Point` values:
`MULTIPOINT(0 0, 20 20, 60 60)`

- A `MultiLineString` with two `LineString` values:
`MULTILINESTRING((10 10, 20 20), (15 15, 30 15))`
- A `MultiPolygon` with two `Polygon` values:
`MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))`
- A `GeometryCollection` consisting of two `Point` values and one `LineString`:
`GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))`

A Backus-Naur grammar that specifies the formal production rules for writing WKT values can be found in the OGC specification document referenced near the beginning of this chapter.

18.3.2. Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation for geometric values is defined by the OpenGIS specifications. It is also defined in the ISO "SQL/MM Part 3: Spatial" standard.

WKB is used to exchange geometry data as binary streams represented by BLOB values containing geometric WKB information.

WKB uses one-byte unsigned integers, four-byte unsigned integers, and eight-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to `POINT(1 1)` consists of this sequence of 21 bytes (each represented here by two hex digits):

```
010100000000000000000000F03F000000000000F03F
```

The sequence may be broken down into these components:

```
Byte order : 01
WKB type   : 01000000
X          : 00000000000000F03F
Y          : 00000000000000F03F
```

Component representation is as follows:

- The byte order may be either 0 or 1 to indicate little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.
- The WKB type is a code that indicates the geometry type. Values from 1 through 7 indicate `Point`, `LineString`, `Polygon`, `MultiPoint`, `MultiLineString`, `MultiPolygon`, and `GeometryCollection`.
- A `Point` value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values are represented by more complex data structures, as detailed in the OpenGIS specification.

18.4. Creating a Spatially Enabled MySQL

Database

This section describes the data types you can use for representing spatial data in MySQL, and the functions available for creating and retrieving spatial values.

18.4.1. MySQL Spatial Data Types

MySQL has data types that correspond to OpenGIS classes. Some of these types hold single geometry values:

- GEOMETRY
- POINT
- LINESTRING
- POLYGON

GEOMETRY can store geometry values of any type. The other single-value types, POINT and LINESTRING and POLYGON, restrict their values to a particular geometry type.

The other data types hold collections of values:

- MULTIPOINT
- MULTILINESTRING
- MULTIPOLYGON
- GEOMETRYCOLLECTION

GEOMETRYCOLLECTION can store a collection of objects of any type. The other collection types, MULTIPOINT and MULTILINESTRING and MULTIPOLYGON and GEOMETRYCOLLECTION, restrict collection members to those having a particular geometry type.

18.4.2. Creating Spatial Values

This section describes how to create spatial values using Well-Known Text and Well-Known Binary functions that are defined in the OpenGIS standard, and using MySQL-specific functions.

18.4.2.1. Creating Geometry Values Using WKT Functions

MySQL provides a number of functions that take as input parameters a Well-Known Text representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromText()` accepts a WKT of any geometry type as its first argument. An implementation also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromText(wkt[,srid])` ,
`GeometryCollectionFromText(wkt[,srid])`

Constructs a GEOMETRYCOLLECTION value using its WKT representation and SRID.

- `GeomFromText(wkt[,srid])`, `GeometryFromText(wkt[,srid])`
Constructs a geometry value of any type using its WKT representation and SRID.
- `LineFromText(wkt[,srid])`, `LineStringFromText(wkt[,srid])`
Constructs a `LINESTRING` value using its WKT representation and SRID.
- `MLineFromText(wkt[,srid])`, `MultiLineStringFromText(wkt[,srid])`
Constructs a `MULTILINESTRING` value using its WKT representation and SRID.
- `MPointFromText(wkt[,srid])`, `MultiPointFromText(wkt[,srid])`
Constructs a `MULTIPOINT` value using its WKT representation and SRID.
- `MPolyFromText(wkt[,srid])`, `MultiPolygonFromText(wkt[,srid])`
Constructs a `MULTIPOLYGON` value using its WKT representation and SRID.
- `PointFromText(wkt[,srid])`
Constructs a `POINT` value using its WKT representation and SRID.
- `PolyFromText(wkt[,srid])`, `PolygonFromText(wkt[,srid])`
Constructs a `POLYGON` value using its WKT representation and SRID.

The OpenGIS specification also describes optional functions for constructing `Polygon` or `MultiPolygon` values based on the WKT representation of a collection of rings or closed `LineString` values. These values may intersect. MySQL does not implement these functions:

- `BdMPolyFromText(wkt,srid)`
Constructs a `MultiPolygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.
- `BdPolyFromText(wkt,srid)`
Constructs a `Polygon` value from a `MultiLineString` value in WKT format containing an arbitrary collection of closed `LineString` values.

18.4.2.2. Creating Geometry Values Using WKB Functions

MySQL provides a number of functions that take as input parameters a `BLOB` containing a Well-Known Binary representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromWKB()` accepts a WKB of any geometry type as its first argument. An implementation

also provides type-specific construction functions for construction of geometry values of each geometry type.

- `GeomCollFromWKB(wkb[,srid])` , `GeometryCollectionFromWKB(wkb[,srid])`
Constructs a `GEOMETRYCOLLECTION` value using its WKB representation and SRID.
- `GeomFromWKB(wkb[,srid])` , `GeometryFromWKB(wkb[,srid])`
Constructs a geometry value of any type using its WKB representation and SRID.
- `LineFromWKB(wkb[,srid])` , `LineStringFromWKB(wkb[,srid])`
Constructs a `LINESTRING` value using its WKB representation and SRID.
- `MLineFromWKB(wkb[,srid])` , `MultiLineStringFromWKB(wkb[,srid])`
Constructs a `MULTILINESTRING` value using its WKB representation and SRID.
- `MPointFromWKB(wkb[,srid])` , `MultiPointFromWKB(wkb[,srid])`
Constructs a `MULTIPOINT` value using its WKB representation and SRID.
- `MPolyFromWKB(wkb[,srid])` , `MultiPolygonFromWKB(wkb[,srid])`
Constructs a `MULTIPOLYGON` value using its WKB representation and SRID.
- `PointFromWKB(wkb[,srid])`
Constructs a `POINT` value using its WKB representation and SRID.
- `PolyFromWKB(wkb[,srid])` , `PolygonFromWKB(wkb[,srid])`
Constructs a `POLYGON` value using its WKB representation and SRID.

The OpenGIS specification also describes optional functions for constructing `Polygon` or `MultiPolygon` values based on the WKB representation of a collection of rings or closed `LineString` values. These values may intersect. MySQL does not implement these functions:

- `BdMPolyFromWKB(wkb,srid)`
Constructs a `MultiPolygon` value from a `MultiLineString` value in WKB format containing an arbitrary collection of closed `LineString` values.
- `BdPolyFromWKB(wkb,srid)`
Constructs a `Polygon` value from a `MultiLineString` value in WKB format containing an

arbitrary collection of closed `LineString` values.

18.4.2.3. Creating Geometry Values Using MySQL-Specific Functions

Note: MySQL does not implement the functions listed in this section.

MySQL provides a set of useful functions for creating geometry WKB representations. The functions described in this section are MySQL extensions to the OpenGIS specifications. The results of these functions are BLOB values containing WKB representations of geometry values with no SRID. The results of these functions can be substituted as the first argument for any function in the `GeomFromWKB()` function family.

- `GeometryCollection(g1,g2,...)`

Constructs a WKB `GeometryCollection`. If any argument is not a well-formed WKB representation of a geometry, the return value is NULL.

- `LineString(pt1,pt2,...)`

Constructs a WKB `LineString` value from a number of WKB `Point` arguments. If any argument is not a WKB `Point`, the return value is NULL. If the number of `Point` arguments is less than two, the return value is NULL.

- `MultiLineString(ls1,ls2,...)`

Constructs a WKB `MultiLineString` value using WKB `LineString` arguments. If any argument is not a WKB `LineString`, the return value is NULL.

- `MultiPoint(pt1,pt2,...)`

Constructs a WKB `MultiPoint` value using WKB `Point` arguments. If any argument is not a WKB `Point`, the return value is NULL.

- `MultiPolygon(poly1,poly2,...)`

Constructs a WKB `MultiPolygon` value from a set of WKB `Polygon` arguments. If any argument is not a WKB `Polygon`, the return value is NULL.

- `Point(x,y)`

Constructs a WKB `Point` using its coordinates.

- `Polygon(ls1,ls2,...)`

Constructs a WKB `Polygon` value from a number of WKB `LineString` arguments. If any argument does not represent the WKB of a `LinearRing` (that is, not a closed and simple `LineString`) the return value is NULL.

18.4.3. Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER TABLE`. Currently, spatial columns are supported only for MyISAM tables.

- Use the `CREATE TABLE` statement to create a table with a spatial column:

```
mysql> CREATE TABLE geom (g GEOMETRY);
Query OK, 0 rows affected (0.02 sec)
```

- Use the `ALTER TABLE` statement to add or drop a spatial column to or from an existing table:

```
mysql> ALTER TABLE geom ADD pt POINT;
Query OK, 0 rows affected (0.00 sec)
Records: 0 Duplicates: 0 Warnings: 0
mysql> ALTER TABLE geom DROP pt;
Query OK, 0 rows affected (0.00 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

18.4.4. Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values into internal geometry format.

You can perform the conversion directly in the `INSERT` statement:

```
INSERT INTO geom VALUES (GeomFromText('POINT(1 1)'));
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (GeomFromText(@g));
```

Or you can perform the conversion prior to the `INSERT`:

```
SET @g = GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomFromText(@g));
```

The preceding examples all use `GeomFromText()` to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (PointFromText(@g));
```

```

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (PolygonFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomCollFromText(@g));

```

Note that if a client application program wants to use WKB representations of geometry values, it is responsible for sending correctly formed WKB in queries to the server. However, there are several ways of satisfying this requirement. For example:

- Inserting a POINT(1 1) value with hex literal syntax:

```

mysql> INSERT INTO geom VALUES
      -> (GeomFromWKB(0x01010000000000000000000000F03F00000000000000F03F));

```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of BLOB type:

```

INSERT INTO geom VALUES (GeomFromWKB(?))

```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string()` and include the result in a query string that is sent to the server. See Section 24.2.3.47, “`mysql_real_escape_string()`”.

18.4.5. Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them into WKT or WKB format.

18.4.5.1. Fetching Spatial Data in Internal Format

Fetching geometry values using internal format can be useful in table-to-table transfers:

```

CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;

```

18.4.5.2. Fetching Spatial Data in WKT Format

The `AsText()` function converts a geometry from internal format into a WKT string.

```

mysql> SELECT AsText(g) FROM geom;
+-----+
| AsText(p1) |
+-----+
| POINT(1 1) |
| LINESTRING(0 0,1 1,2 2) |
+-----+

```

18.4.5.3. Fetching Spatial Data in WKB Format

The `AsBinary()` function converts a geometry from internal format into a BLOB containing the WKB value.

```
SELECT AsBinary(g) FROM geom;
```

18.5. Analyzing Spatial Information

After populating spatial columns with values, you are ready to query and analyze them. MySQL provides a set of functions to perform various operations on spatial data. These functions can be grouped into four major categories according to the type of operation they perform:

- Functions that convert geometries between various formats
- Functions that provide access to qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

Spatial analysis functions can be used in many contexts, such as:

- Any interactive SQL program, such as **mysql** or **MySQLCC**
- Application programs written in any language that supports a MySQL client API

18.5.1. Geometry Format Conversion Functions

MySQL supports the following functions for converting geometry values between internal format and either WKT or WKB format:

- `AsBinary(g)`

Converts a value in internal geometry format to its WKB representation and returns the binary result.

- `AsText(g)`

Converts a value in internal geometry format to its WKT representation and returns the string result.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(GeomFromText(@g));
+-----+
| AsText(GeomFromText(@G)) |
+-----+
| LINESTRING(1 1,2 2,3 3) |
+-----+
```

- `GeomFromText(wkt[, srid])`

Converts a string value from its WKT representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromText()` and `LineFromText()`; see Section 18.4.2.1, “Creating Geometry Values Using WKT Functions”.

- `GeomFromWKB(wkb[,srid])`

Converts a binary value from its WKB representation into internal geometry format and returns the result. A number of type-specific functions are also supported, such as `PointFromWKB()` and `LineFromWKB()`; see Section 18.4.2.2, “Creating Geometry Values Using WKB Functions”.

18.5.2. Geometry Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return `NULL` if the argument is of an incorrect geometry type. For example, `Area()` returns `NULL` if the object type is neither `Polygon` nor `MultiPolygon`.

18.5.2.1. General Geometry Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

- `Dimension(g)`

Returns the inherent dimension of the geometry value *g*. The result can be #1, 0, 1, or 2. (The meaning of these values is given in Section 18.2.2, “Class Geometry”.)

```
mysql> SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
+-----+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
+-----+
```

- `Envelope(g)`

Returns the Minimum Bounding Rectangle (MBR) for the geometry value *g*. The result is returned as a `Polygon` value.

```
mysql> SELECT AsText(Envelope(GeomFromText('LineString(1 1,2 2)')));
+-----+
| AsText(Envelope(GeomFromText('LineString(1 1,2 2)'))) |
+-----+
| POLYGON((1 1,2 1,2 2,1 2,1 1)) |
+-----+
```

The polygon is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- `GeometryType(g)`

Returns as a string the name of the geometry type of which the geometry instance g is a member. The name corresponds to one of the instantiable `Geometry` subclasses.

```
mysql> SELECT GeometryType(GeomFromText('POINT(1 1)'));
+-----+
| GeometryType(GeomFromText('POINT(1 1)')) |
+-----+
| POINT                                     |
+-----+
```

- `SRID(g)`

Returns an integer indicating the Spatial Reference System ID for the geometry value g .

In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

```
mysql> SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));
+-----+
| SRID(GeomFromText('LineString(1 1,2 2)',101)) |
+-----+
|                                               101 |
+-----+
```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- `Boundary(g)`

Returns a geometry that is the closure of the combinatorial boundary of the geometry value g .

- `IsEmpty(g)`

Returns 1 if the geometry value g is the empty geometry, 0 if it is not empty, and #1 if the argument is NULL. If the geometry is empty, it represents the empty point set.

- `IsSimple(g)`

Currently, this function is a placeholder and should not be used. If implemented, its behavior will be as described in the next paragraph.

Returns 1 if the geometry value g has no anomalous geometric points, such as self-intersection or self-tangency. `IsSimple()` returns 0 if the argument is not simple, and #1 if it is NULL.

The description of each instantiable geometric class given earlier in the chapter includes the specific conditions that cause an instance of that class to be classified as not simple.

18.5.2.2. Point Functions

A `Point` consists of X and Y coordinates, which may be obtained using the following functions:

- $X(p)$

Returns the X-coordinate value for the point p as a double-precision number.

```
mysql> SELECT X(GeomFromText('Point(56.7 53.34)'));
+-----+
| X(GeomFromText('Point(56.7 53.34)')) |
+-----+
|                               56.7 |
+-----+
```

- $Y(p)$

Returns the Y-coordinate value for the point p as a double-precision number.

```
mysql> SELECT Y(GeomFromText('Point(56.7 53.34)'));
+-----+
| Y(GeomFromText('Point(56.7 53.34)')) |
+-----+
|                               53.34 |
+-----+
```

18.5.2.3. LineString Functions

A `LineString` consists of `Point` values. You can extract particular points of a `LineString`, count the number of points that it contains, or obtain its length.

- $EndPoint(ls)$

Returns the `Point` that is the end point of the `LineString` value ls .

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(EndPoint(GeomFromText(@ls)));
+-----+
| AsText(EndPoint(GeomFromText(@ls))) |
+-----+
| POINT(3 3) |
+-----+
```

- $GLength(ls)$

Returns as a double-precision number the length of the `LineString` value ls in its associated spatial reference.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT GLength(GeomFromText(@ls));
+-----+
| GLength(GeomFromText(@ls)) |
+-----+
|          2.8284271247462 |
+-----+
```

```
+-----+
```

- `IsClosed(ls)`

Returns 1 if the `LineString` value *ls* is closed (that is, its `StartPoint()` and `EndPoint()` values are the same). Returns 0 if *ls* is not closed, and #1 if it is NULL.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT IsClosed(GeomFromText(@ls));
+-----+
| IsClosed(GeomFromText(@ls)) |
+-----+
|                               0 |
+-----+
```

- `NumPoints(ls)`

Returns the number of points in the `LineString` value *ls*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT NumPoints(GeomFromText(@ls));
+-----+
| NumPoints(GeomFromText(@ls)) |
+-----+
|                               3 |
+-----+
```

- `PointN(ls,n)`

Returns the *n*-th point in the `LineString` value *ls*. Point numbers begin at 1.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(PointN(GeomFromText(@ls),2));
+-----+
| AsText(PointN(GeomFromText(@ls),2)) |
+-----+
| POINT(2 2)                          |
+-----+
```

- `StartPoint(ls)`

Returns the `Point` that is the start point of the `LineString` value *ls*.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(StartPoint(GeomFromText(@ls)));
+-----+
| AsText(StartPoint(GeomFromText(@ls))) |
```

```
+-----+
| POINT(1 1) |
+-----+
```

The OpenGIS specification also defines the following function, which MySQL does not implement:

- `IsRing(ls)`

Returns 1 if the `LineString` value *ls* is closed (that is, its `StartPoint()` and `EndPoint()` values are the same) and is simple (does not pass through the same point more than once). Returns 0 if *ls* is not a ring, and #1 if it is NULL.

18.5.2.4. MultiLineString Functions

- `GLength(mls)`

Returns as a double-precision number the length of the `MultiLineString` value *mls*. The length of *mls* is equal to the sum of the lengths of its elements.

```
mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT GLength(GeomFromText(@mls));
+-----+
| GLength(GeomFromText(@mls)) |
+-----+
|                4.2426406871193 |
+-----+
```

- `IsClosed(mls)`

Returns 1 if the `MultiLineString` value *mls* is closed (that is, the `StartPoint()` and `EndPoint()` values are the same for each `LineString` in *mls*). Returns 0 if *mls* is not closed, and #1 if it is NULL.

```
mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT IsClosed(GeomFromText(@mls));
+-----+
| IsClosed(GeomFromText(@mls)) |
+-----+
|                                0 |
+-----+
```

18.5.2.5. Polygon Functions

- `Area(poly)`

Returns as a double-precision number the area of the `Polygon` value *poly*, as measured in its spatial reference system.

```
mysql> SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT Area(GeomFromText(@poly));
+-----+
```

```

| Area(GeomFromText(@poly)) |
+-----+
|                               4 |
+-----+

```

- ExteriorRing(*poly*)

Returns the exterior ring of the Polygon value *poly* as a LineString.

```

mysql> SET @poly =
      -> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(ExteriorRing(GeomFromText(@poly)));
+-----+
| AsText(ExteriorRing(GeomFromText(@poly))) |
+-----+
| LINESTRING(0 0,0 3,3 3,3 0,0 0) |
+-----+

```

- InteriorRingN(*poly*, *n*)

Returns the *n*-th interior ring for the Polygon value *poly* as a LineString. Ring numbers begin at 1.

```

mysql> SET @poly =
      -> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
+-----+
| AsText(InteriorRingN(GeomFromText(@poly),1)) |
+-----+
| LINESTRING(1 1,1 2,2 2,2 1,1 1) |
+-----+

```

- NumInteriorRings(*poly*)

Returns the number of interior rings in the Polygon value *poly*.

```

mysql> SET @poly =
      -> 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT NumInteriorRings(GeomFromText(@poly));
+-----+
| NumInteriorRings(GeomFromText(@poly)) |
+-----+
|                               1 |
+-----+

```

18.5.2.6. MultiPolygon Functions

- Area(*mpoly*)

Returns as a double-precision number the area of the `MultiPolygon` value *mpoly*, as measured in its spatial reference system.

```
mysql> SET @mpoly =
      -> 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT Area(GeomFromText(@mpoly));
+-----+
| Area(GeomFromText(@mpoly)) |
+-----+
|                             8 |
+-----+
```

The OpenGIS specification also defines the following functions, which MySQL does not implement:

- `Centroid(mpoly)`

Returns the mathematical centroid for the `MultiPolygon` value *mpoly* as a `Point`. The result is not guaranteed to be on the `MultiPolygon`.

- `PointOnSurface(mpoly)`

Returns a `Point` value that is guaranteed to be on the `MultiPolygon` value *mpoly*.

18.5.2.7. GeometryCollection Functions

- `GeometryN(gc, n)`

Returns the *n*-th geometry in the `GeometryCollection` value *gc*. Geometry numbers begin at 1.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT AsText(GeometryN(GeomFromText(@gc),1));
+-----+
| AsText(GeometryN(GeomFromText(@gc),1)) |
+-----+
| POINT(1 1)                             |
+-----+
```

- `NumGeometries(gc)`

Returns the number of geometries in the `GeometryCollection` value *gc*.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT NumGeometries(GeomFromText(@gc));
+-----+
| NumGeometries(GeomFromText(@gc)) |
+-----+
|                                   2 |
+-----+
```

18.5.3. Functions That Create New Geometries from Existing Ones

18.5.3.1. Geometry Functions That Produce New Geometries

In the section Section 18.5.2, “Geometry Functions”, we've discussed some functions that can construct new geometries from the existing ones:

- `Envelope(g)`
- `StartPoint(ls)`
- `EndPoint(ls)`
- `PointN(ls,n)`
- `ExteriorRing(poly)`
- `InteriorRingN(poly,n)`
- `GeometryN(gc,n)`

18.5.3.2. Spatial Operators

OpenGIS proposes a number of other functions that can produce geometries. They are designed to implement spatial operators.

These functions are not implemented in MySQL. They may appear in future releases.

- `Buffer(g,d)`
Returns a geometry that represents all points whose distance from the geometry value *g* is less than or equal to a distance of *d*.
- `ConvexHull(g)`
Returns a geometry that represents the convex hull of the geometry value *g*.
- `Difference(g1,g2)`
Returns a geometry that represents the point set difference of the geometry value *g1* with *g2*.
- `Intersection(g1,g2)`
Returns a geometry that represents the point set intersection of the geometry values *g1* with *g2*.
- `SymDifference(g1,g2)`
Returns a geometry that represents the point set symmetric difference of the geometry value *g1* with *g2*.
- `Union(g1,g2)`

Returns a geometry that represents the point set union of the geometry values $g1$ and $g2$.

18.5.4. Functions for Testing Spatial Relations Between Geometric Objects

The functions described in these sections take two geometries as input parameters and return a qualitative or quantitative relation between them.

18.5.5. Relations on Geometry Minimal Bounding Rectangles (MBRs)

MySQL provides some functions that can test relations between minimal bounding rectangles of two geometries $g1$ and $g2$. They include:

- `MBRContains($g1$, $g2$)`

Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangle of $g1$ contains the Minimum Bounding Rectangle of $g2$.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRContains(@g2,@g1);
+-----+-----+
| MBRContains(@g1,@g2) | MBRContains(@g2,@g1) |
+-----+-----+
|                      1 |                      0 |
+-----+-----+
```

- `MBRDisjoint($g1$, $g2$)`

Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangles of the two geometries $g1$ and $g2$ are disjoint (do not intersect).

- `MBREqual($g1$, $g2$)`

Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangles of the two geometries $g1$ and $g2$ are the same.

- `MBRIntersects($g1$, $g2$)`

Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangles of the two geometries $g1$ and $g2$ intersect.

- `MBROverlaps($g1$, $g2$)`

Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangles of the two geometries $g1$ and $g2$ overlap.

- `MBRTouches(g1, g2)`

Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangles of the two geometries *g1* and *g2* touch.

- `MBRWithin(g1, g2)`

Returns 1 or 0 to indicate whether or not the Minimum Bounding Rectangle of *g1* is within the Minimum Bounding Rectangle of *g2*.

```
mysql> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
```

```
+-----+-----+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+-----+-----+
|                1 |                0 |
+-----+-----+
```

18.5.6. Functions That Test Spatial Relationships Between Geometries

The OpenGIS specification defines the following functions. Currently, MySQL does not implement them according to the specification. Those that are implemented return the same result as the corresponding MBR-based functions. This includes functions in the following list other than `Distance()` and `Related()`.

These functions may be implemented in future releases with full support for spatial analysis, not just MBR-based support.

The functions operate on two geometry values *g1* and *g2*.

- `Contains(g1, g2)`

Returns 1 or 0 to indicate whether or not *g1* completely contains *g2*.

- `Crosses(g1, g2)`

Returns 1 if *g1* spatially crosses *g2*. Returns NULL if *g1* is a Polygon or a MultiPolygon, or if *g2* is a Point or a MultiPoint. Otherwise, returns 0.

The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
- Their intersection is not equal to either of the two given geometries

- `Disjoint(g1,g2)`
Returns 1 or 0 to indicate whether or not *g1* is spatially disjoint from (does not intersect) *g2*.
- `Distance(g1,g2)`
Returns as a double-precision number the shortest distance between any two points in the two geometries.
- `Equals(g1,g2)`
Returns 1 or 0 to indicate whether or not *g1* is spatially equal to *g2*.
- `Intersects(g1,g2)`
Returns 1 or 0 to indicate whether or not *g1* spatially intersects *g2*.
- `Overlaps(g1,g2)`
Returns 1 or 0 to indicate whether or not *g1* spatially overlaps *g2*. The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.
- `Related(g1,g2,pattern_matrix)`
Returns 1 or 0 to indicate whether or not the spatial relationship specified by *pattern_matrix* exists between *g1* and *g2*. Returns #1 if the arguments are NULL. The pattern matrix is a string. Its specification will be noted here if this function is implemented.
- `Touches(g1,g2)`
Returns 1 or 0 to indicate whether or not *g1* spatially touches *g2*. Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.
- `Within(g1,g2)`
Returns 1 or 0 to indicate whether or not *g1* is spatially within *g2*.

18.6. Optimizing Spatial Analysis

Search operations in non-spatial databases can be optimized using indexes. This is true for spatial databases as well. With the help of a great variety of multi-dimensional indexing methods that have previously been designed, it is possible to optimize spatial searches. The most typical of these are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** to index spatial columns. A spatial index is built using the MBR of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

18.6.1. Creating Spatial Indexes

MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but extended with the `SPATIAL` keyword. Spatial columns that are indexed currently must be declared `NOT NULL`. The following examples demonstrate how to create spatial indexes.

- With `CREATE TABLE`:

```
mysql> CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
```

- With `ALTER TABLE`:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With `CREATE INDEX`:

```
mysql> CREATE SPATIAL INDEX sp_index ON geom (g);
```

To drop spatial indexes, use `ALTER TABLE` or `DROP INDEX`:

- With `ALTER TABLE`:

```
mysql> ALTER TABLE geom DROP INDEX g;
```

- With `DROP INDEX`:

```
mysql> DROP INDEX sp_index ON geom;
```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
```

Field	Type	Null	Key	Default	Extra
fid	int(11)		PRI	NULL	auto_increment
g	geometry				

2 rows in set (0.00 sec)

```
mysql> SELECT COUNT(*) FROM geom;
```

count(*)
32376

1 row in set (0.00 sec)

To add a spatial index on the column g, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376 Duplicates: 0 Warnings: 0
```

18.6.2. Using a Spatial Index

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the `WHERE` clause. For example, let's say we want to find all objects that are in the given rectangle:

```
mysql> SELECT fid,AsText(g) FROM geom WHERE
mysql> MBRContains(GeomFromText('Polygon((30000 15000,31000 15000,31000 16000,3
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| fid | AsText(g)
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 21 | LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30333.8 15828.8)

| 154 | LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30278 15134)
| 155 | LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30259 15083.4)
| 157 | LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4,30128.8 15001)
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
20 rows in set (0.00 sec)
```

Lets use `EXPLAIN` to check the way this query is executed (the `id` column has been removed so the output better fits the page):

```
mysql> EXPLAIN SELECT fid,AsText(g) FROM geom WHERE
mysql> MBRContains(GeomFromText('Polygon((30000 15000,31000 15000,31000 16000,3
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| select_type | table | type | possible_keys | key | key_len | ref | rows |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| SIMPLE      | geom | range | g              | g   | 32      | NULL | 50 |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

Lets check what would happen without a spatial index:

```
mysql> EXPLAIN SELECT fid,AsText(g) FROM g IGNORE INDEX (g) WHERE
mysql> MBRContains(GeomFromText('Polygon((30000 15000,31000 15000,31000 16000,3
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| select_type | table | type | possible_keys | key | key_len | ref | rows |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| SIMPLE      | geom | ALL  | NULL          | NULL | NULL    | NULL | 32376 |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

1 row in set (0.00 sec)

Let's execute the SELECT statement, ignoring the spatial key we have:

```
mysql> SELECT fid,AsText(g) FROM geom IGNORE INDEX (g) WHERE
mysql> MBRContains(GeomFromText('Polygon((30000 15000,31000 15000,31000 16000,3
```

fid	AsText(g)
1	LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136.4,30240 15127.

20 rows in set (0.46 sec)

When the index is not used, the execution time for this query rises from 0.00 seconds to 0.46 seconds.

In future releases, spatial indexes may also be used for optimizing other functions. See Section 18.5.4, “Functions for Testing Spatial Relations Between Geometric Objects”.

18.7. MySQL Conformance and Compatibility

18.7.1. GIS Features That Are Not Yet Implemented

- Additional Metadata Views

OpenGIS specifications propose several additional metadata views. For example, a system view named `GEOMETRY_COLUMNS` contains a description of geometry columns, one row for each geometry column in the database.

- The OpenGIS function `Length()` on `LineString` and `MultiLineString` currently should be called in MySQL as `GLength()`

The problem is that there is an existing SQL function `Length()` which calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context. We need either to solve this somehow, or decide on another function name.

Chapter 19. Stored Procedures and Functions

Stored procedures and functions are a new feature in MySQL version 5.0. A stored procedure is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored procedure instead.

Some situations where stored procedures can be particularly useful:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures for all common operations. This provides a consistent and secure environment, and procedures can ensure that each operation is properly logged. In such a setup, applications and users would not get any access to the database tables directly, but can only execute specific stored procedures.

Stored procedures can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server system because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored procedures also allow you to have libraries of functions in the database server. This is a feature shared by modern application languages that allow such design internally, for example, by using classes. Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored procedures, which is also used by IBM's DB2.

The MySQL implementation of stored procedures is still in progress. All syntax described in this chapter is supported and any limitations and extensions are documented where appropriate.

19.1. Stored Procedures and the Grant Tables

Stored procedures require the `proc` table in the `mysql` database. This table is created during the MySQL 5.0 installation procedure. If you are upgrading to MySQL 5.0 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See Section 2.10.7, “Upgrading the Grant Tables”.

Beginning with MySQL 5.0.3, the grant system has been modified to take stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine. Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which allows users who have access to the database with which the routine is associated to execute the routine.

19.2. Stored Procedure Syntax

Stored procedures and functions are routines that are created with `CREATE PROCEDURE` and `CREATE FUNCTION` statements. A routine is either a procedure or a function. A procedure is invoked using a `CALL` statement, and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. Stored routines may call other stored routines.

As of MySQL 5.0.1, a stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are disallowed.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

(In MySQL 5.0.0, stored routines are global and not associated with a database. They inherit the default database from the caller. If a `USE db_name` is executed within the routine, the original default database is restored upon routine exit.)

MySQL supports the very useful extension that allows the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1.

The following sections describe the syntax used to create, alter, drop, and query stored procedures and functions.

19.2.1. CREATE PROCEDURE and CREATE FUNCTION

```
CREATE PROCEDURE sp_name ([parameter[,...]])
    [characteristic ...] routine_body
```

```
CREATE FUNCTION sp_name ([parameter[,...]])
    RETURNS type
    [characteristic ...] routine_body
```

```
parameter:
    [ IN | OUT | INOUT ] param_name type
```

```
type:
    Any valid MySQL data type
```

```
characteristic:
    LANGUAGE SQL
    | [NOT] DETERMINISTIC
    | SQL SECURITY {DEFINER | INVOKER}
    | COMMENT 'string'
```

```
routine_body:
    Valid SQL procedure statements or statements
```

These statements create a stored routine. As of MySQL 5.0.3, to create a routine, it is necessary to have the `CREATE ROUTINE` privilege for it, and the `ALTER ROUTINE` and `EXECUTE` privileges are granted automatically to its creator.

By default, the routine is associated with the current database. To associate the routine explicitly with a given database, specify the name as `db_name . sp_name` when you create it.

If the routine name is the same as the name of a built-in SQL function, you need to use a space between the name and the following parenthesis when defining the routine, or a syntax error occurs. This is also true when you invoke the routine later.

The RETURNS clause may be specified only for a FUNCTION, for which it is mandatory. It is used to indicate the return type of the function, and the function body must contain a RETURN value statement.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of () should be used. Each parameter is an IN parameter by default. To specify otherwise for a parameter, use the keyword OUT or INOUT before the parameter name. Specifying IN, OUT, or INOUT is only valid for a PROCEDURE.

The CREATE FUNCTION statement is used in earlier versions of MySQL to support UDFs (User Defined Functions). See Section 27.2, "Adding New Functions to MySQL". UDFs continue to be supported, even with the existence of stored functions. A UDF can be regarded as an external stored function. However, do note that stored functions share their namespace with UDFs.

A framework for external stored procedures will be introduced in the near future. This will allow you to write stored procedures in languages other than SQL. Most likely, one of the first languages to be supported is PHP because the core PHP engine is small, thread-safe, and can easily be embedded. Because the framework is public, it is expected that many other languages can also be supported.

A procedure or function is considered "deterministic" if it always produces the same result for the same input parameters, and "not deterministic" otherwise. Currently, the DETERMINISTIC characteristic is accepted, but not yet used by the optimizer.

The SQL SECURITY characteristic can be used to specify whether the routine should be executed using the permissions of the user who creates the routine or the user who invokes it. The default value is DEFINER. This feature is new in SQL:2003. The creator or invoker must have permission to access the database with which the routine is associated. As of MySQL 5.0.3, it is necessary to have the EXECUTE privilege to be able to execute the routine. The user that must have this privilege is either the definer or invoker, depending on how the SQL SECURITY characteristic is set.

MySQL stores the sql_mode system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force.

The COMMENT clause is a MySQL extension, and may be used to describe the stored procedure. This information is displayed by the SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION statements.

MySQL allows routines to contain DDL statements (such as CREATE and DROP) and SQL transaction statements (such as COMMIT). This is not required by the standard and therefore is implementation-specific.

Stored routines cannot use LOAD DATA INFILE.

Note: Currently, stored functions created with CREATE FUNCTION may not contain references to tables. Please note that this includes some SET statements, but excludes some SELECT statements. This limitation will be lifted as soon as possible.

The following is an example of a simple stored procedure that uses an OUT parameter. The example uses the **mysql** client `delimiter` command to change the statement delimiter from ; to // while the procedure is being defined. This allows the ; delimiter used in the procedure body to be passed through to the server rather than being interpreted by **mysql** itself.

```
mysql> delimiter //
mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
-> BEGIN
->   SELECT COUNT(*) INTO param1 FROM t;
-> END
-> //
```

```

Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a;
+-----+
| @a    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)

```

When using the `delimiter` command, you should avoid the use of the backslash (`\`) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result:

```

mysql> delimiter //

mysql> CREATE FUNCTION hello (s CHAR(20)) RETURNS CHAR(50)
      -> RETURN CONCAT('Hello, ',s,'!');
      -> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)

```

If the `RETURN` statement in a stored function returns a value that has a different type than is specified in the function's `RETURNS` clause, the return value is coerced to the proper type. For example, if a function returns an `ENUM` or `SET` value, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member or set of `SET` members.

19.2.2. ALTER PROCEDURE and ALTER FUNCTION

```

ALTER {PROCEDURE | FUNCTION} sp_name [characteristic ...]

characteristic:
    SQL SECURITY {DEFINER | INVOKER}
    | COMMENT 'string'

```

This statement can be used to change the characteristics of a stored procedure or function. You must have the `ALTER ROUTINE` privilege for the routine as of MySQL 5.0.3. This privilege is granted automatically to the routine creator.

More than one change may be specified in an `ALTER PROCEDURE` or `ALTER FUNCTION` statement.

19.2.3. DROP PROCEDURE and DROP FUNCTION

```

DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name

```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the ALTER ROUTINE privilege for the routine as of MySQL 5.0.3. This privilege is granted automatically to the routine creator.

The IF EXISTS clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with SHOW WARNINGS.

19.2.4. SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION

```
SHOW CREATE {PROCEDURE | FUNCTION} sp_name
```

This statement is a MySQL extension. Similar to SHOW CREATE TABLE, it returns the exact string that can be used to re-create the named routine.

```
mysql> SHOW CREATE FUNCTION test.hello\G
***** 1. row *****
      Function: hello
      sql_mode:
Create Function: CREATE FUNCTION `test`.`hello`(s CHAR(20)) RETURNS CHAR(50)
RETURN CONCAT('Hello, ',s, '!')
```

19.2.5. SHOW PROCEDURE STATUS and SHOW FUNCTION STATUS

```
SHOW {PROCEDURE | FUNCTION} STATUS [LIKE 'pattern']
```

This statement is a MySQL extension. It returns characteristics of routines, such as the database, name, type, creator, and creation and modification dates. If no pattern is specified, the information for all stored procedures or all stored functions is listed, depending on which statement you use.

```
mysql> SHOW FUNCTION STATUS LIKE 'hello'\G
***** 1. row *****
      Db: test
      Name: hello
      Type: FUNCTION
      Definer: testuser@localhost
      Modified: 2004-08-03 15:29:37
      Created: 2004-08-03 15:29:37
      Security_type: DEFINER
      Comment:
```

You can also get information about stored routines from the ROUTINES table in INFORMATION_SCHEMA. See Section 22.1.14, “The INFORMATION_SCHEMA ROUTINES Table”.

19.2.6. CALL Statement

```
CALL sp_name([parameter[, ...]])
```

The CALL statement invokes a procedure that was defined previously with CREATE PROCEDURE.

CALL can pass back values to its caller using parameters that are declared as OUT or INOUT parameters. It also “returns” the number of rows affected, which a client program can obtain at the SQL level by calling the ROW_COUNT() function and from C by calling the mysql_affected_rows() C API function.

19.2.7. BEGIN . . . END Compound Statement

```
[begin_label:] BEGIN
  [statement_list]
END [end_label]
```

Stored routines may contain multiple statements, using a `BEGIN . . . END` compound statement.

A compound statement can be labeled. `end_label` cannot be given unless `begin_label` also is present, and if both are present, they must be the same.

Please note that the optional `[NOT] ATOMIC` clause is not yet supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

Using multiple statements requires that a client is able to send query strings containing the `;` statement delimiter. This is handled in the `mysql` command-line client with the `delimiter` command. Changing the `;` end-of-query delimiter (for example, to `//`) allows `;` to be used in a routine body.

19.2.8. DECLARE Statement

The `DECLARE` statement is used to define various items local to a routine: local variables (see Section 19.2.9, “Variables in Stored Procedures”), conditions and handlers (see Section 19.2.10, “Conditions and Handlers”) and cursors (see Section 19.2.11, “Cursors”). `SIGNAL` and `RESIGNAL` statements are not currently supported.

`DECLARE` may be used only inside a `BEGIN . . . END` compound statement and must be at its start, before any other statements.

Cursors must be declared before declaring handlers, and variables and conditions must be declared before declaring either cursors or handlers.

19.2.9. Variables in Stored Procedures

You may declare and use variables within a routine.

19.2.9.1. DECLARE Local Variables

```
DECLARE var_name[,...] type [DEFAULT value]
```

This statement is used to declare local variables. To provide a default value for the variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

The scope of a local variable is within the `BEGIN . . . END` block where it is declared. It can be used in nested blocks except those that declare a variable with the same name.

19.2.9.2. Variable SET Statement

```
SET var_name = expr [, var_name = expr] ...
```

The `SET` statement in stored procedures is an extended version of the general `SET` statement. Referenced variables may be ones declared inside a routine, or global server variables.

The `SET` statement in stored procedures is implemented as part of the pre-existing `SET` syntax. This allows an extended syntax of `SET a=x, b=y, . . .` where different variable types (locally declared variables and global and session server variables) can be mixed. This also allows combinations of local variables and some options that make sense only for system variables; in that case, the options are recognized but ignored.

19.2.9.3. SELECT ... INTO Statement

```
SELECT col_name[,...] INTO var_name[,...] table_expr
```

This SELECT syntax stores selected columns directly into variables. Therefore, only a single row may be retrieved.

```
SELECT id,data INTO x,y FROM test.t1 LIMIT 1;
```

19.2.10. Conditions and Handlers

Certain conditions may require specific handling. These conditions can relate to errors, as well as general flow control inside a routine.

19.2.10.1. DECLARE Conditions

```
DECLARE condition_name CONDITION FOR condition_value
```

```
condition_value:
    SQLSTATE [VALUE] sqlstate_value
    | mysql_error_code
```

This statement specifies conditions that need specific handling. It associates a name with a specified error condition. The name can subsequently be used in a DECLARE HANDLER statement. See Section 19.2.10.2, “DECLARE Handlers”.

In addition to SQLSTATE values, MySQL error codes are also supported.

19.2.10.2. DECLARE Handlers

```
DECLARE handler_type HANDLER FOR condition_value[,...] sp_statement
```

```
handler_type:
    CONTINUE
    | EXIT
    | UNDO

condition_value:
    SQLSTATE [VALUE] sqlstate_value
    | condition_name
    | SQLWARNING
    | NOT FOUND
    | SQLEXCEPTION
    | mysql_error_code
```

This statement specifies handlers that each may deal with one or more conditions. If one of these conditions occurs, the specified statement is executed.

For a CONTINUE handler, execution of the current routine continues after execution of the handler statement. For an EXIT handler, execution of the current BEGIN...END compound statement is terminated. The UNDO handler type statement is not yet supported.

- SQLWARNING is shorthand for all SQLSTATE codes that begin with 01.
- NOT FOUND is shorthand for all SQLSTATE codes that begin with 02.
- SQLEXCEPTION is shorthand for all SQLSTATE codes not caught by SQLWARNING or NOT FOUND.

In addition to SQLSTATE values, MySQL error codes are also supported.

For example:

```
mysql> CREATE TABLE test.t (s1 int,primary key (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
-> BEGIN
->   DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
->   SET @x = 1;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 2;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 3;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo()//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

Notice that @x is 3, which shows that MySQL executed to the end of the procedure. If the line `DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;` had not been present, MySQL would have taken the default (EXIT) path after the second `INSERT` failed due to the `PRIMARY KEY` constraint, and `SELECT @x` would have returned 2.

19.2.11. Cursors

Simple cursors are supported inside stored procedures and functions. The syntax is as in embedded SQL. Cursors are currently asensitive, read-only, and non-scrolling. Asensitive means that the server may or may not make a copy of its result table.

Cursors must be declared before declaring handlers, and variables and conditions must be declared before declaring either cursors or handlers.

For example:

```
CREATE PROCEDURE curdemo()
BEGIN
  DECLARE done INT DEFAULT 0;
  DECLARE a CHAR(16);
  DECLARE b,c INT;
  DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
  DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
  DECLARE CONTINUE HANDLER FOR SQLSTATE '02000' SET done = 1;

  OPEN cur1;
  OPEN cur2;

  REPEAT
    FETCH cur1 INTO a, b;
    FETCH cur2 INTO c;
    IF NOT done THEN
      IF b < c THEN
        INSERT INTO test.t3 VALUES (a,b);
```

```

        ELSE
            INSERT INTO test.t3 VALUES (a,c);
        END IF;
    END IF;
UNTIL done END REPEAT;

CLOSE cur1;
CLOSE cur2;
END

```

19.2.11.1. Declaring Cursors

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor. Multiple cursors may be defined in a routine, but each cursor in a block must have a unique name.

The SELECT statement cannot have an INTO clause.

19.2.11.2. Cursor OPEN Statement

```
OPEN cursor_name
```

This statement opens a previously declared cursor.

19.2.11.3. Cursor FETCH Statement

```
FETCH cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row (if a row exists) using the specified open cursor, and advances the cursor pointer.

19.2.11.4. Cursor CLOSE Statement

```
CLOSE cursor_name
```

This statement closes a previously opened cursor.

If not closed explicitly, a cursor is closed at the end of the compound statement in which it was declared.

19.2.12. Flow Control Constructs

The IF, CASE, LOOP, WHILE, ITERATE, and LEAVE constructs are fully implemented.

These constructs may each contain either a single statement, or a block of statements using the BEGIN ... END compound statement. Constructs may be nested.

FOR loops are not currently supported.

19.2.12.1. IF Statement

```

IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF

```

IF implements a basic conditional construct. If the *search_condition* evaluates to true, the corresponding SQL statement list is executed. If no *search_condition* matches, the statement list in the ELSE clause is executed. *statement_list* can consist of one or more statements.

Please note that there is also an IF() *function*, which differs from the IF *statement* described here.. See Section 12.2, "Control Flow Functions".

19.2.12.2. CASE Statement

```
CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

Or:

```
CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

The CASE statement for stored procedures implements a complex conditional construct. If a *search_condition* evaluates to true, the corresponding SQL statement is executed. If no search condition matches, the statement in the ELSE clause is executed.

Note: The syntax of a CASE *statement* shown here for use inside a stored procedure differs slightly from that of the SQL CASE *expression* described in Section 12.2, "Control Flow Functions". The CASE statement cannot have an ELSE NULL clause, and it is terminated with END CASE instead of END.

19.2.12.3. LOOP Statement

```
[begin_label:] LOOP
  statement_list
END LOOP [end_label]
```

LOOP implements a simple loop construct, enabling repeated execution of a particular statement or statements. The statements within the loop are repeated until the loop is exited; usually this is accomplished with a LEAVE statement.

A LOOP statement can be labeled. *end_label* cannot be given unless *begin_label* also is present, and if both are present, they must be the same.

19.2.12.4. LEAVE Statement

```
LEAVE label
```

This statement is used to exit any labeled flow control construct. It can be used with BEGIN ... END or loops.

19.2.12.5. ITERATE Statement

```
ITERATE label
```

ITERATE can only appear within LOOP, REPEAT, and WHILE statements. ITERATE means "do the loop again."

For example:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END
```

19.2.12.6. REPEAT Statement

```
[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement or statements within a REPEAT statement are repeated until the *search_condition* is true.

A REPEAT statement can be labeled. *end_label* cannot be given unless *begin_label* also is present, and if both are present, they must be the same.

For example:

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)
```

19.2.12.7. WHILE Statement

```
[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]
```

The statement or statements within a WHILE statement are repeated as long as the *search_condition* is true.

A WHILE statement can be labeled. *end_label* cannot be given unless *begin_label* also is present, and if both are present, they must be the same.

For example:

```
CREATE PROCEDURE dowhile()  
BEGIN  
    DECLARE v1 INT DEFAULT 5;  
  
    WHILE v1 > 0 DO  
        . . .  
        SET v1 = v1 - 1;  
    END WHILE;  
END
```

Chapter 20. Triggers

Rudimentary support for triggers is included beginning with MySQL 5.0.2. A trigger is a named database object that is associated with a table and that activates when a particular event occurs for the table. For example, the following statements set up a table, as well as a trigger for INSERT statements into the table. The trigger sums the values inserted into one of the table's columns:

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
```

This chapter describes the syntax for creating and dropping triggers, and show some examples of how to use them.

20.1. CREATE TRIGGER Syntax

```
CREATE TRIGGER trigger_name trigger_time trigger_event
ON tbl_name FOR EACH ROW trigger_stmt
```

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table.

The trigger becomes associated with the table named *tbl_name*. *tbl_name* must refer to a permanent table. You cannot associate a trigger with a TEMPORARY table or a view.

trigger_time is the trigger action time. It can be BEFORE or AFTER to indicate that the trigger activates before or after the statement that activated it.

trigger_event indicates the kind of statement that activates the trigger. It can be INSERT, UPDATE, or DELETE. For example, a BEFORE trigger for INSERT statements could be used to check the values to be inserted into new rows.

There cannot be two triggers for a given table that have the same trigger action time and event. For example, you cannot have two BEFORE UPDATE triggers for a table. But you can have a BEFORE UPDATE and a BEFORE INSERT trigger, or a BEFORE UPDATE and an AFTER UPDATE trigger.

trigger_stmt is the statement to execute when the trigger activates. If you want to execute multiple statements, use the BEGIN ... END compound statement construct. This also enables you to use the same statements that are allowable within stored routines. See Section 19.2.7, “BEGIN ... END Compound Statement”.

Note: Currently, triggers have the same limitation as stored functions that they may not contain direct references to tables by name. This limitation will be lifted as soon as possible.

Although direct table references are not allowed in the triggered statement, you can refer to columns in the table associated with the trigger by using the names OLD and NEW. OLD.*col_name* refers to a column of an existing row before it is updated or deleted. NEW.*col_name* refers to the column of a new row to be inserted or an existing row after it is updated.

Use of SET NEW.*col_name* = *value* requires the UPDATE privilege on the column. Use of SET *var_name* = NEW.*col_name* requires the SELECT privilege on the column.

The CREATE TRIGGER statement requires the SUPER privilege. It was added in MySQL 5.0.2.

20.2. DROP TRIGGER Syntax

```
DROP TRIGGER tbl_name.trigger_name
```

Drops a trigger. The name of the trigger to drop must include the table name because each trigger is associated with a particular table.

The `DROP TRIGGER` statement requires the `SUPER` privilege. It was added in MySQL 5.0.2.

20.3. Using Triggers

Support for triggers is included beginning with MySQL 5.0.2. Currently, trigger support is rudimentary, so there are certain limitations on what you can do with them. This section discusses how to use triggers and what the current limitations are.

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is associated with a table and is defined to activate when an `INSERT`, `DELETE`, or `UPDATE` statement for the table executes. A trigger can be set to activate either before or after the triggering statement. For example, you can have a trigger activate before each row that is deleted from a table or after each row that is updated.

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement. The syntax for these statements is described in Section 20.1, “`CREATE TRIGGER Syntax`” and Section 20.2, “`DROP TRIGGER Syntax`”.

Here is a simple example that associates a trigger with a table for `INSERT` statements. It acts as an accumulator to sum the values inserted into one of the columns of the table.

The following statements create a table and a trigger for it:

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
      -> FOR EACH ROW SET @sum = @sum + NEW.amount;
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger activation time, the triggering event, and what to do with the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger should activate before each row inserted into the table. The other allowable keyword here is `AFTER`.
- The keyword `INSERT` indicates the event that activates the trigger. In the example, `INSERT` statements cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` statements.
- The statement following `FOR EACH ROW` defines the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering statement. In the example, the triggered statement is a simple `SET` that accumulates the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
| 1852.48                |
```

+-----+

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100` or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. The trigger name must include the table name:

```
mysql> DROP TRIGGER account.ins_sum;
```

Because a trigger is associated with a particular table, you cannot have multiple triggers for a table that have the same name. You should also be aware that the namespace for triggers might change in the future from table to database. That is, the requirement that trigger names be unique for a given table might be strengthened to the requirement that they be unique within the database. For better forward compatibility with future development, try to use trigger names that do not overlap within a database.

In addition to the requirement that trigger names be unique for a table, there are other limitations on the types of triggers you can create. In particular, you cannot have two triggers for a table that have the same activate time and activation event. For example, you cannot define two `BEFORE INSERT` triggers or two `AFTER UPDATE` triggers for a table. This should rarely be a significant limitation, because it is possible to define a trigger that executes multiple statements by using the `BEGIN ... END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

There are also limitations on what can appear in the statement that the trigger executes when activated:

- The trigger cannot refer directly to tables by name, including the table with which the trigger is associated. You can, however, use the keywords `OLD` and `NEW`. `OLD` refers to an existing row to be deleted or a row to be updated before the update occurs. `NEW` refers to a new row to be inserted or an updated row after the update occurs.
- The trigger cannot invoke stored procedures using the `CALL` statement. (This means, for example, that you cannot get around the prohibition on referring to tables by name by invoking a stored procedure that refers to the tables.)
- The trigger cannot use statements that begin or end a transaction such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`.

The `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. (`OLD` and `NEW` are not case sensitive.) In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read-only. You can refer to it but not modify it. A column named with `NEW` can be referred to if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or that are used to update a row.

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the automatically generated sequence number that will be generated when the new record actually is inserted.

`OLD` and `NEW` are MySQL extensions to triggers.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is allowed within stored routines such as conditionals and loops. However, just as for stored routines, when you define a trigger that ex-

ecutes multiple statements, it becomes necessary to redefine the statement delimiter if you are entering the trigger with the **mysql** program so that you can use the ';' character within the trigger definition. The following example illustrates these points. It defines an UPDATE trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a BEFORE trigger because the value needs to be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
-> FOR EACH ROW
-> BEGIN
->     IF NEW.amount < 0 THEN
->         SET NEW.amount = 0;
->     ELSEIF NEW.amount > 100 THEN
->         SET NEW.amount = 100;
->     END IF;
-> END//
mysql> delimiter ;
```

It might occur to you that it would be easier to define a stored procedure separately and then invoke it from the trigger using a simple CALL statement. That would also be advantageous if you wanted to invoke the same routine from within several triggers. However, a limitation on triggers is that CALL cannot be used. You have to write out the compound statement in each CREATE TRIGGER statement where you want to use it.

Chapter 21. Views

Views (including updatable views) are implemented in the 5.0 version of MySQL Server. Views are available in binary releases from 5.0.1 and up.

This chapter discusses the following topics:

- Creating or altering views with `CREATE VIEW` or `ALTER VIEW`
- Destroying views with `DROP VIEW`
- Displaying view metadata with `SHOW CREATE VIEW`

To use views if you have upgraded to MySQL 5.0.1 from an older release, you should upgrade your grant tables so that they contain the view-related privileges. See Section 2.10.7, “Upgrading the Grant Tables”.

21.1. ALTER VIEW Syntax

```
ALTER [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]  
VIEW view_name [(column_list)]  
AS select_statement  
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of an existing view. The syntax is similar to that for `CREATE VIEW`. See Section 21.2, “`CREATE VIEW` Syntax”. This statement requires the `CREATE VIEW` and `DELETE` privileges for the view, and some privilege for each column referred to in the `SELECT` statement.

This statement was added in MySQL 5.0.1.

21.2. CREATE VIEW Syntax

```
CREATE [OR REPLACE] [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]  
VIEW view_name [(column_list)]  
AS select_statement  
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement creates a new view, or replaces an existing one if the `OR REPLACE` clause is given. The *select_statement* is a `SELECT` statement that provides the definition of the view. The statement can select from base tables or other views.

This statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DELETE` privilege for the view.

A view belongs to a database. By default, a new view is created in the current database. To create the view explicitly in a given database, specify the name as *db_name.view_name* when you create it.

```
mysql> CREATE VIEW test.v AS SELECT * FROM t;
```

Tables and views share the same namespace within a database, so a database cannot contain a table and a view that have the same name.

Views must have unique column names with no duplicates, just like base tables. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, the optional `column_list` clause can be given as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

Columns retrieved by the `SELECT` statement can be simple references to table columns. They can also be expressions that use functions, constant values, operators, and so forth.

Unqualified table or view names in the `SELECT` statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the proper database name.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty  | price | value |
+-----+-----+-----+
|    3 |    50 |   150 |
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system or user variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Within a stored routine, the definition cannot refer to routine parameters or local variables.
- Any table or view referred to in the definition must exist. However, after a view has been created, it is possible to drop a table or view that the definition refers to. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- The tables named in the view definition must already exist.
- You cannot associate a trigger with a view.

`ORDER BY` is allowed in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

If you create a view and then change the query processing environment by changing system variables, that may affect the results you get from the view:

```
mysql> CREATE VIEW v AS SELECT CHARSET(CHAR(65)), COLLATION(CHAR(65));
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SET NAMES 'latin1';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT * FROM v;
+-----+-----+
| CHARSET(CHAR(65)) | COLLATION(CHAR(65)) |
+-----+-----+
| latin1            | latin1_swedish_ci   |
+-----+-----+
1 row in set (0.00 sec)
```

```
mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT * FROM v;
+-----+-----+
| CHARSET(CHAR(65)) | COLLATION(CHAR(65)) |
+-----+-----+
| utf8              | utf8_general_ci     |
+-----+-----+
1 row in set (0.00 sec)
```

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. The default algorithm is `UNDEFINED` if no `ALGORITHM` clause is present. The algorithm affects how MySQL processes the view.

For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.

For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.

A reason to choose `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` three ways:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

The `MERGE` algorithm requires a one-to relationship between the rows in the view and the rows in the underlying table. If this relationship does not hold, a temporary table must be used instead. Lack of a one-to-one relationship occurs if the view contains any of a number of constructs:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `UNION` or `UNION ALL`
- Refers only to literal values (in this case, there is no underlying table)

Some views are updatable. That is, you can use them in statements such as `UPDATE`, `DELETE`, or `INSERT` to update the contents of the underlying table. For a view to be updatable, there must be a one-to relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`

- HAVING
- UNION or UNION ALL
- Subquery in the select list
- Join
- Non-updatable view in the FROM clause
- A subquery in the WHERE clause that refers to a table in the FROM clause
- Refers only to literal values (in this case, there is no underlying table to update)
- ALGORITHM = TEMPTABLE (use of a temporary table always makes a view non-updatable)

With respect to insertability (being updatable with INSERT statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references and not derived columns. A derived column is one that is not a simple column reference but is derived from an expression. These are examples of derived columns:

```
3.14159  
col1 + 3  
UPPER(col2)  
col3 / col4  
(subquery)
```

A view that has a mix of simple column references and derived columns is not insertable, but it can be updatable if you update only those columns that are not derived. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because col2 is derived from an expression. But it is updatable if the update does not try to update col2. This update is allowable:

```
UPDATE v SET col1 = 0;
```

This update is not allowable because it attempts to update a derived column:

```
UPDATE v SET col2 = 0;
```

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the MERGE algorithm. For this to work, the view must use an inner join (not an outer join or a UNION). Also, only a single table in the view definition can be updated, so the SET clause must name only columns from one of the tables in the view. Views that use UNION ALL are disallowed even though they might be theoretically updatable, because the implementation uses temporary tables to process them.

For a multiple-table updatable view, INSERT can work if it inserts into a single table. DELETE is not supported.

The WITH CHECK OPTION clause can be given for an updatable view to prevent inserts or up-

dates to rows except those for which the `WHERE` clause in the `select_statement` is true.

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADE` keywords determine the scope of check testing when the view is defined in terms of another view. `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADE` causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is `CASCADE`. Consider the definitions for the following table and set of views:

```
mysql> CREATE TABLE t1 (a INT);
mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
-> WITH CHECK OPTION;
mysql> CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
-> WITH LOCAL CHECK OPTION;
mysql> CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
-> WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADE` check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```
q1> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See Section 5.3.3, “Server System Variables”.

The `CREATE VIEW` statement was added in MySQL 5.0.1. The `WITH CHECK OPTION` clause was implemented in MySQL 5.0.2.

`INFORMATION_SCHEMA` contains a `VIEWS` table from which information about view objects can be obtained. See Section 22.1.15, “The `INFORMATION_SCHEMA VIEWS` Table”.

21.3. DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]
      view_name [, view_name] ...
      [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view.

You can use the keywords `IF EXISTS` to prevent an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each non-existent view. See Section 13.5.4.20, “`SHOW WARNINGS` Syntax”.

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

This statement was added in MySQL 5.0.1.

21.4. SHOW CREATE VIEW Syntax

```
SHOW CREATE VIEW view_name
```

This statement shows a `CREATE VIEW` statement that creates the given view.

```
mysql> SHOW CREATE VIEW v;
+-----+-----+
| Table | Create Table |
```

```
+-----+-----+  
| v      | CREATE VIEW `test`.`v` AS select 1 AS `a`,2 AS `b` |  
+-----+-----+
```

This statement was added in MySQL 5.0.1.

Chapter 22. INFORMATION_SCHEMA Database

The Information

INFORMATION_SCHEMA support is available in MySQL 5.0.2 and later. It provides access to database metadata.

``Metadata" is data about the data, such as the name of a database or table, the data type of a column, or access privileges. Other terms that sometimes are used for this information are ``data dictionary" or ``system catalog."

Here is an example:

```
mysql> SELECT table_name, table_type, engine
-> FROM information_schema.tables
-> WHERE table_schema = 'db5'
-> ORDER BY table_name DESC;
```

table_name	table_type	engine
v56	VIEW	NULL
v3	VIEW	NULL
v2	VIEW	NULL
v	VIEW	NULL
tables	BASE TABLE	MyISAM
t7	BASE TABLE	MyISAM
t3	BASE TABLE	MyISAM
t2	BASE TABLE	MyISAM
t	BASE TABLE	MyISAM
pk	BASE TABLE	InnoDB
loop	BASE TABLE	MyISAM
kurs	BASE TABLE	MyISAM
k	BASE TABLE	MyISAM
into	BASE TABLE	MyISAM
goto	BASE TABLE	MyISAM
fk2	BASE TABLE	InnoDB
fk	BASE TABLE	InnoDB

17 rows in set (0.01 sec)

Explanation: The statement requests a list of all the tables in database db5, in reverse alphabetical order, showing just three pieces of information: the name of the table, its type, and its engine.

INFORMATION_SCHEMA is the ``information database", the place that stores information about all the other databases that the MySQL server maintains. Inside INFORMATION_SCHEMA there are several read-only tables. They are actually views, not base tables, so you won't actually see any file associated with them.

Each MySQL user has the right to access these tables, but only the rows in the tables that correspond to objects for which the user has the proper access privileges.

Advantages of SELECT

The SELECT ... FROM INFORMATION_SCHEMA statement is intended as a more consistent way to provide access to the information provided by the various SHOW statements that MySQL supports (SHOW DATABASES, SHOW TABLES, and so forth). Using SELECT has these advantages, compared to SHOW:

- It conforms to Codd's rules. That is, all access is done on tables.

- Nobody needs to learn a new statement syntax. Because they already know how `SELECT` works, they only need to learn the object names.
- The implementor need not worry about adding keywords.
- There are millions of possible output variations, instead of just one. This provides more flexibility for applications that have varying requirements about what metadata they need.
- Migration is easier because every other DBMS does it this way.

However, because `SHOW` is popular with MySQL employees and users, and because it might be confusing were it to disappear, the advantages of conventional syntax are not a sufficient reason to eliminate `SHOW`. In fact, there are enhancements to `SHOW` in MySQL 5.0, too. These are described in Section 22.2, “Extensions to `SHOW` Statements”.

Standards

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 “Schemata.” Our intent is approximate compliance with SQL:2003 core feature F021 “Basic information schema.”

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the `engine` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `sycat` or `system`, the standard name is `INFORMATION_SCHEMA`.

In effect, we have a new “database” named `information_schema`, though there is never a need to make a file by that name. It is possible to select `INFORMATION_SCHEMA` as the default database with a `USE` statement, but the only way to access the contents of its tables is with `SELECT`. You cannot insert into them, update them, or delete from them.

Privileges

There is no difference between the current (`SHOW`) privilege requirement and the `SELECT` requirement. In either case, you have to have some privilege on an object in order to see information about it.

22.1. INFORMATION_SCHEMA Tables

Explanation of following sections

In the following sections, we take the tables and columns that are in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “Standard Name” indicates the standard SQL name for the column.
- “SHOW name” indicates what the equivalent field name is in the closest `SHOW` statement, if any.
- “Remarks” provides additional information where applicable. We have marked “omit” those columns for which MySQL has no present use. We have omitted these columns, that is, they appear in the standard but not in MySQL. So their presence here is a matter of record only.

To avoid using any name that's reserved in the standard or in DB2 or in SQL Server or in Oracle we changed the names of columns marked “MySQL extension.” (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: <http://www.dbazine.com/gulutzan5.shtml>.

The definition for character columns (for example, TABLES.TABLE_NAME), is generally VARCHAR(N) CHARACTER SET utf8 where N is at least 64.

Each section indicates what SHOW statement is equivalent to a SELECT that retrieves information from INFORMATION_SCHEMA, or else that there is no such equivalent statement.

Note: At present, there are some missing columns and some columns out of order. We are working on this and intend to update the documentation as changes are made.

22.1.1. The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the SCHEMATA table provides information about databases.

Standard Name	SHOW name	Remarks
CATALOG_NAME	-	NULL
SCHEMA_NAME		Database
SCHEMA_OWNER		omit
DE- FAULT_CHARACTER_SET_CATALOG		omit
DE- FAULT_CHARACTER_SET_SCHEMA		omit
DEFAULT_CHARACTER_SET_NAME		
DEFAULT_COLLATION_NAME		
SQL_PATH		NULL

Notes:

- For SQL_PATH, we might eventually support something in MySQL 5.x. For now, it's always NULL.
- DEFAULT_COLLATION_NAME was added in MySQL 5.0.6.

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
  FROM INFORMATION_SCHEMA.SCHEMATA
  [WHERE SCHEMA_NAME LIKE 'wild']
```

```
SHOW DATABASES
  [LIKE 'wild']
```

22.1.2. The INFORMATION_SCHEMA TABLES Table

The TABLES table provides information about tables in databases.

Standard Name	SHOW name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA	Table_...	
TABLE_NAME	Table_...	
TABLE_TYPE		
SELF_REFERENCING_COLUMN_NAME		omit

The INFORMATION_SCHEMA Information
Database

REFERENCE_GENERATION		omit
USER_DEFINED_TYPE_NAME		omit
IS_INSERTABLE_INTO		omit
IS_TYPED		omit
COMMIT_ACTION		omit
ENGINE	Engine	MySQL extension
VERSION	Version	MySQL extension
ROW_FORMAT	Row_format	MySQL extension
TABLE_ROWS	Rows	MySQL extension
AVG_ROW_LENGTH	Avg_row_length	MySQL extension
DATA_LENGTH	Data_length	MySQL extension
MAX_DATA_LENGTH	Max_data_length	MySQL extension
INDEX_LENGTH	Index_length	MySQL extension
DATA_FREE	Data_free	MySQL extension
AUTO_INCREMENT	Auto_increment	MySQL extension
CREATE_TIME	Create_time	MySQL extension
UPDATE_TIME	Update_time	MySQL extension
CHECK_TIME	Check_time	MySQL extension
TABLE_COLLATION	Collation	MySQL extension
CHECKSUM	Checksum	MySQL extension
CREATE_OPTIONS	Create_options	MySQL extension
TABLE_COMMENT	Comment	MySQL extension

Notes:

- TABLE_SCHEMA and TABLE_NAME are a single field in a SHOW display, for example Table_in_db1.
- TABLE_TYPE should be BASE TABLE or VIEW. If table is temporary, then TABLE_TYPE = TEMPORARY. (There are no temporary views, so this is not ambiguous.)
- We have nothing for the table's default character set. TABLE_COLLATION is close, because collation names begin with a character set name.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
  [WHERE table_schema = 'db_name']
  [WHERE|AND table_name LIKE 'wild']
```

```
SHOW TABLES
  [FROM db_name]
  [LIKE 'wild']
```

22.1.3. The INFORMATION_SCHEMA COLUMNS Table

The COLUMNS table provides information about columns in tables.

Standard Name	SHOW name	Remarks
TABLE_CATALOG		NULL

The INFORMATION_SCHEMA Information
Database

TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME	Field	
ORDINAL_POSITION		see notes
COLUMN_DEFAULT	Default	
IS_NULLABLE	Null	
DATA_TYPE	Type	
CHARACTER_MAXIMUM_LENGTH	Type	
CHARACTER_OCTET_LENGTH		
NUMERIC_PRECISION	Type	
NUMERIC_PRECISION_RADIX		omit
NUMERIC_SCALE	Type	
DATETIME_PRECISION		omit
INTERVAL_TYPE		omit
INTERVAL_PRECISION		omit
CHARACTER_SET_CATALOG		omit
CHARACTER_SET_SCHEMA		omit
CHARACTER_SET_NAME		
COLLATION_CATALOG		omit
COLLATION_SCHEMA		omit
COLLATION_NAME	Collation	
DOMAIN_NAME		omit
UDT_CATALOG		omit
UDT_SCHEMA		omit
UDT_NAME		omit
SCOPE_CATALOG		omit
SCOPE_SCHEMA		omit
SCOPE_NAME		omit
MAXIMUM_CARDINALITY		omit
DTD_IDENTIFIER		omit
IS_SELF_REFERENCING		omit
IS_IDENTITY		omit
IDENTITY_GENERATION		omit
IDENTITY_START		omit
IDENTITY_INCREMENT		omit
IDENTITY_MAXIMUM		omit
IDENTITY_MINIMUM		omit
IDENTITY_CYCLE		omit
IS_GENERATED		omit
GENERATION_EXPRESSION		omit
COLUMN_KEY	Key	MySQL extension
EXTRA	Extra	MySQL extension
COLUMN_COMMENT	Comment	MySQL extension

Notes:

- In SHOW, the Type display includes values from several different COLUMNS columns.
- ORDINAL_POSITION is necessary because you might someday want to say ORDER BY ORDINAL_POSITION. Unlike SHOW, SELECT does not have automatic ordering.
- CHARACTER_OCTET_LENGTH should be the same as CHARACTER_MAXIMUM_LENGTH, except for multi-byte character sets.
- CHARACTER_SET_NAME can be derived from Collation. For example, if you say SHOW FULL COLUMNS FROM t, and you see in the Collation column a value of latin1_swedish_ci, the character set is what's before the first underscore: latin1.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']
```

```
SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE wild]
```

22.1.4. The INFORMATION_SCHEMA STATISTICS Table

The STATISTICS table provides information about table indexes.

Standard Name	SHOW name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		= Database
TABLE_NAME	Table	
NON_UNIQUE	Non_unique	
INDEX_SCHEMA		= Database
INDEX_NAME	Key_name	
TYPE		omit
SEQ_IN_INDEX	Seq_in_index	
COLUMN_NAME	Column_name	
COLLATION	Collation	
CARDINALITY	Cardinality	
PAGES		omit
FILTER_CONDITION		omit
SUB_PART	Sub_part	MySQL extension
PACKED	Packed	MySQL extension
NULLABLE	Null	MySQL extension
INDEX_TYPE	Index_type	MySQL extension
COMMENT	Comment	MySQL extension

Notes:

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
WHERE table_name = 'tbl_name'
[AND schema_name = 'db_name']
```

```
SHOW INDEX
FROM tbl_name
[FROM db_name]
```

22.1.5. The INFORMATION_SCHEMA USER_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

Standard Name	SHOW name	Remarks
GRANTEE		e.g. 'user'@'host'
TABLE_CATALOG		NULL
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- This is a non-standard table. It takes its values from the `mysql.user` table.

22.1.6. The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

Standard Name	SHOW name	Remarks
GRANTEE		e.g. 'user'@'host'
TABLE_CATALOG		NULL
TABLE_SCHEMA		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- This is a non-standard table. It takes its values from the `mysql.db` table.

22.1.7. The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The TABLE_PRIVILEGES table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

Standard Name	SHOW name	Remarks
GRANTOR		omit
GRANTEE		e.g. 'user'@'host'
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		
WITH_HIERARCHY		omit

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

PRIVILEGE_TYPE can contain one (and only one) of these values: SELECT, INSERT, UPDATE, REFERENCES, ALTER, INDEX, DROP, CREATE VIEW.

22.1.8. The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The COLUMN_PRIVILEGES table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

Standard Name	SHOW name	Remarks
GRANTOR		omit
GRANTEE		e.g. 'user'@'host'
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one row per privilege, and it's uppercase.
- `PRIVILEGE_TYPE` can contain one (and only one) of these values: SELECT, INSERT, UPDATE, REFERENCES.

- If the user has GRANT OPTION privilege, then IS_GRANTABLE should be YES. Otherwise, IS_GRANTABLE should be NO. The output does not list GRANT OPTION as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

22.1.9. The INFORMATION_SCHEMA CHARACTER_SETS Table

The CHARACTER_SETS table provides information about available character sets.

Standard Name	SHOW name	Remarks
CHARACTER_SET_CATALOG		omit
CHARACTER_SET_SCHEMA		omit
CHARACTER_SET_NAME	Charset	
CHARACTER_REPERTOIRE		omit
FORM_OF_USE		omit
NUMBER_OF_CHARACTERS		omit
DEFAULT_COLLATE_CATALOG		omit
DEFAULT_COLLATE_SCHEMA		omit
DEFAULT_COLLATE_NAME	Default collation	
DESCRIPTION	Description	MySQL extension
MAXLEN	Maxlen	MySQL extension

Notes:

- We have added two non-standard columns corresponding to the Description and Maxlen columns in the output from SHOW CHARACTER SET.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE name LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

22.1.10. The INFORMATION_SCHEMA COLLATIONS Table

The COLLATIONS table provides information about collations for each character set.

Standard Name	SHOW name	Remarks
COLLATION_CATALOG		omit
COLLATION_SCHEMA		omit

COLLATION_NAME	Collation	
PAD_ATTRIBUTE		omit
COLLATION_TYPE		omit
COLLATION_DEFINITION		omit
COLLATION_DICTIONARY		omit
CHARACTER_SET_NAME		omit MySQL extension
ID		omit MySQL extension
IS_DEFAULT		omit MySQL extension
IS_COMPILED		omit MySQL extension
SORTLEN		omit MySQL extension

Notes:

- We have added five non-standard columns corresponding to the Charset, Id, Default, Compiled, and Sortlen columns in the output from SHOW COLLATION.

The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
  [WHERE collation_name LIKE 'wild']
```

```
SHOW COLLATION
  [LIKE 'wild']
```

22.1.11. The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The COLLATION_CHARACTER_SET_APPLICABILITY table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from SHOW COLLATION.

Standard Name	SHOW name	Remarks
COLLATION_CATALOG		omit
COLLATION_SCHEMA		omit
COLLATION_NAME	Collation	
CHARACTER_SET_CATALOG		omit
CHARACTER_SET_SCHEMA		omit
CHARACTER_SET_NAME	Charset	

22.1.12. The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The TABLE_CONSTRAINTS table describes which tables have constraints.

Standard Name	SHOW name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		

TABLE_CATALOG		omit
TABLE_SCHEMA		
TABLE_NAME		
CONSTRAINT_TYPE		
IS_DEFERRABLE		omit
INITIALLY_DEFERRED		omit

Notes:

- The CONSTRAINT_TYPE value can be UNIQUE, PRIMARY KEY, or FOREIGN KEY.
- The UNIQUE and PRIMARY KEY information is about the same as what you get from the Key_name field in the output from SHOW INDEX when the Non_unique field is 0.
- The CONSTRAINT_TYPE column can contain one of these values: UNIQUE, PRIMARY KEY, FOREIGN KEY, CHECK. This is a CHAR (not ENUM) column. The CHECK value is not available until we support CHECK.

22.1.13. The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The KEY_COLUMN_USAGE table describes which key columns have constraints.

Standard Name	SHOW name	Remarks
CONSTRAINT_CATALOG		NULL
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_CATALOG		
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
ORDINAL_POSITION		
POSITION_IN_UNIQUE_CONSTRAINT		
REFERENCED_TABLE_SCHEMA		
REFERENCED_TABLE_NAME		
REFERENCED_COLUMN_NAME		

Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of ORDINAL_POSITION is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of POSITION_IN_UNIQUE_CONSTRAINT is NULL for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

For example, suppose that there are two tables name t1 and t3 that have the following definitions:

```
CREATE TABLE t1
(
    s1 INT,
    s2 INT,
    s3 INT,
    PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
    s1 INT,
    s2 INT,
    s3 INT,
    KEY(s1),
    CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the KEY_COLUMN_USAGE table has two rows:

- One row with CONSTRAINT_NAME='PRIMARY', TABLE_NAME='t1', COLUMN_NAME='s3', ORDINAL_POSITION=1, POSITION_IN_UNIQUE_CONSTRAINT=NULL.
- One row with CONSTRAINT_NAME='CO', TABLE_NAME='t3', COLUMN_NAME='s2', ORDINAL_POSITION=1, POSITION_IN_UNIQUE_CONSTRAINT=1.
- REFERENCED_TABLE_SCHEMA, REFERENCED_TABLE_NAME, and REFERENCED_COLUMN_NAME were added in MySQL 5.0.6.

22.1.14. The INFORMATION_SCHEMA ROUTINES Table

The ROUTINES table provides information about stored routines (both procedures and functions). The ROUTINES table does not include user-defined functions (UDFs) at this time.

The column named ``mysql.proc name" indicates the mysql.proc table column that corresponds to the INFORMATION_SCHEMA.ROUTINES table column, if any.

Standard Name	mysql.proc name	Remarks
SPECIFIC_CATALOG		omit
SPECIFIC_SCHEMA	db	omit
SPECIFIC_NAME	specific_name	
ROUTINE_CATALOG		NULL
ROUTINE_SCHEMA	db	
ROUTINE_NAME	name	
MODULE_CATALOG		omit
MODULE_SCHEMA		omit
MODULE_NAME		omit
USER_DEFINED_TYPE_CATALOG		omit
USER_DEFINED_TYPE_SCHEMA		omit
USER_DEFINED_TYPE_NAME		omit
ROUTINE_TYPE	type	{ PROCEDURE FUNCTION }
DTD_IDENTIFIER		(data type descriptor)

The INFORMATION_SCHEMA Information
Database

ROUTINE_BODY		SQL
ROUTINE_DEFINITION	body	
EXTERNAL_NAME		NULL
EXTERNAL_LANGUAGE	language	NULL
PARAMETER_STYLE		SQL
IS_DETERMINISTIC	is_deterministic	
SQL_DATA_ACCESS	sql_data_access	
IS_NULL_CALL		omit
SQL_PATH		NULL
SCHEMA_LEVEL_ROUTINE		omit
MAX_DYNAMIC_RESULT_SETS		omit
IS_USER_DEFINED_CAST		omit
IS_IMPLICITLY_INVOCABLE		omit
SECURITY_TYPE	security_type	
TO_SQL_SPECIFIC_CATALOG		omit
TO_SQL_SPECIFIC_SCHEMA		omit
TO_SQL_SPECIFIC_NAME		omit
AS_LOCATOR		omit
CREATED	created	
LAST_ALTERED	modified	
NEW_SAVEPOINT_LEVEL		omit
IS_UDT_DEPENDENT		omit
RES- ULT_CAST_FROM_DTD_IDENTIFI ER		omit
RESULT_CAST_AS_LOCATOR		omit
SQL_MODE	sql_mode	MySQL extension
ROUTINE_COMMENT	comment	MySQL extension
DEFINER	definer	MySQL extension

Notes:

- MySQL calculates EXTERNAL_LANGUAGE thus:
 - If `mysql.proc.language = 'SQL'`, then EXTERNAL_LANGUAGE is NULL
 - Otherwise, EXTERNAL_LANGUAGE is what's in `mysql.proc.language`. However, we don't have external languages yet, so it's always NULL.

22.1.15. The INFORMATION_SCHEMA VIEWS Table

The VIEWS table provides information about views in databases.

Standard Name	SHOW name	Remarks
TABLE_CATALOG		NULL
TABLE_SCHEMA		
TABLE_NAME		

VIEW_DEFINITION		
CHECK_OPTION		
IS_UPDATABLE		
INSERTABLE_INTRO		omit

Notes:

- There is a new privilege, SHOW VIEW, without which you cannot see the VIEWS table.
- The VIEW_DEFINITION column has most of what you see in the Create Table field that SHOW CREATE VIEW produces. Skip the words before SELECT and skip the words WITH CHECK OPTION. For example, if the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
```

then the view definition is:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The CHECK_OPTION column always has a value of NONE.
- The IS_UPDATABLE column is YES if the view is updatable, NO if the view is not updatable.

22.1.16. Other INFORMATION_SCHEMA Tables

We will add more INFORMATION_SCHEMA tables soon. Particularly, we acknowledge the need for INFORMATION_SCHEMA.PARAMETERS and for INFORMATION_SCHEMA.REFERENTIAL_CONSTRAINTS and for INFORMATION_SCHEMA.TRIGGERS.

22.2. Extensions to SHOW Statements

Some extensions to SHOW statements accompany the implementation of INFORMATION_SCHEMA:

- SHOW can be used to get information about the structure of INFORMATION_SCHEMA itself.
- Several SHOW statements accept a WHERE clause that provides more flexibility in specifying which rows to display.

These extensions are available beginning with MySQL 5.0.3.

INFORMATION_SCHEMA is an information database, so its name is included in the output from SHOW DATABASES. Similarly, SHOW TABLES can be used with INFORMATION_SCHEMA to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_information_schema |
+-----+
| SCHEMATA                     |
| TABLES                      |
+-----+
```

The INFORMATION_SCHEMA Information
Database

```

COLUMNS
CHARACTER_SETS
COLLATIONS
COLLATION_CHARACTER_SET_APPLICABILITY
ROUTINES
STATISTICS
VIEWS
USER_PRIVILEGES
SCHEMA_PRIVILEGES
TABLE_PRIVILEGES
COLUMN_PRIVILEGES
TABLE_CONSTRAINTS
KEY_COLUMN_USAGE

```

SHOW COLUMNS and DESCRIBE can display information about the columns in individual INFORMATION_SCHEMA tables.

Several SHOW statement have been extended to allow a WHERE clause:

```

SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW KEYS
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW VARIABLES

```

The WHERE clause, if present, is evaluated against the column names displayed by the SHOW statement. For example, the SHOW COLLATION statement produces these output columns:

For example, the SHOW CHARACTER SET statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
```

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
dec8	DEC West European	dec8_swedish_ci	1
cp850	DOS West European	cp850_general_ci	1
hp8	HP West European	hp8_english_ci	1
koi8r	KOI8-R Relcom Russian	koi8r_general_ci	1
latin1	ISO 8859-1 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1

...

To use a WHERE clause with SHOW CHARACTER SET, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string "japanese":

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
```

Charset	Description	Default collation	Maxlen
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3

This statement displays the multi-byte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
```

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
euckr	EUC-KR Korean	euckr_korean_ci	2
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
utf8	UTF-8 Unicode	utf8_general_ci	3
ucs2	UCS-2 Unicode	ucs2_general_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3

Chapter 23. Precision Math

MySQL 5 introduces precision math, that is, numeric value handling that results in more accurate results and more control over invalid values than in earlier versions of MySQL. Precision math is based on two implementation changes:

- The introduction of new SQL modes in MySQL 5.0.2 that control how strict the server is about accepting or rejecting invalid data.
- The introduction in MySQL 5.0.3 of a library for fixed-point arithmetic.

These changes have several implications for numeric operations:

- More precise calculations.

For exact-value numbers, calculations do not introduce floating-point error. Instead, exact precision is used. For example, a number such as .0001 is treated as an exact value rather than as an approximate value, and summing it 10,000 times produces a result of 1, not a value "close" to 1.

- Well-defined rounding behavior.

For the exact-value numbers, the result of `ROUND()` depends on its argument, not on factors such as how the underlying C library works.

- Improved platform independence.

Operations on exact numeric values are the same across different platforms such as Windows and Unix.

- Control over invalid value handling.

Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the `sql_mode` system variable.

An important result of these changes is that MySQL provides improved compliance with standard SQL.

The following discussion covers several aspects of how precision math works (including possible incompatibilities with older applications). At the end, some examples are given that demonstrate how MySQL 5 handles numeric operations more precisely than before.

23.1. Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (`DECIMAL` and integer types) and exact-value numeric literals. Approximate-value data types and numeric literals still are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Numbers that look similar need not be both exact-value or both approximate-value. For example,

2.34 is an exact-value (fixed-point) number, whereas 2.34E0 is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

23.2. DECIMAL Data Type Changes

In MySQL 5.0.3, several changes were made to several aspects of the `DECIMAL` data type (and its synonyms):

- Maximum number of digits
- Storage format
- Storage requirements
- The non-standard MySQL extension to the upper range of `DECIMAL` columns

Some of these changes result in possible incompatibilities for applications that are written for older versions of MySQL. These incompatibilities are noted throughout this section.

The declaration syntax for a `DECIMAL` column remains `DECIMAL(M,D)`, although the range of values for the arguments has changed somewhat:

- *M* is the maximum number of digits (the precision). It has a range of 1 to 64. This introduces a possible incompatibility for older applications, because previous versions of MySQL allow a range of 1 to 254.
- *D* is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than *M*.

The maximum value of 64 for *M* means that calculations on `DECIMAL` values are accurate up to 64 digits. This limit of 64 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals is different from before. (Prior to MySQL 5.0.3, decimal values could have up to 254 digits. However, calculations were done using floating-point and thus were approximate, not exact.) This change in the range of literal values is another possible source of incompatibility for older applications.

Values for `DECIMAL` columns no longer are represented as strings that require one byte per digit or sign character. Instead, a binary format is used that packs nine decimal digits into four bytes. This change to `DECIMAL` storage format changes the storage requirements as well. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the "leftover" digits require some fraction of four bytes. For example, a `DECIMAL(18,9)` column has nine digits on each side of the decimal point, so the integer part and the fractional part each require four bytes. A `DECIMAL(20,10)` column has 10 digits on each side of the decimal point. Each part requires four bytes for nine of the digits, and one byte for the remaining digit.

The storage required for "leftover" digits is given by the following table:

Leftover	Number
Digits	of Bytes
0	0

1	1
2	1
3	2
4	2
5	3
6	3
7	4
8	4
9	4

As a result of the change from string to numeric format for `DECIMAL` storage, `DECIMAL` columns no longer store a leading '+' character or leading '0' digits. Before MySQL 5.0.3, if you inserted '+0003.1' into a `DECIMAL(5,1)` column, it would be stored as +0003.1. As of MySQL 5.0.3, it is stored as 3.1. Applications that rely on the older behavior must be modified to account for this change.

The change of storage format also means that `DECIMAL` columns no longer support the non-standard extension that allowed values larger than the range implied by the column definition. Formerly, one byte was allocated for storing the sign character. For positive values that needed no sign byte, MySQL allowed an extra digit to be stored instead. For example, a `DECIMAL(3,0)` column must support a range of at least -999 to 999, but MySQL would allow storing values from 1000 to 9999 as well, by using the sign byte to store an extra digit. This extension to the upper range of `DECIMAL` columns no longer is allowed. In MySQL 5.0.3 and up, a `DECIMAL(M,D)` column allows at most $M-D$ digits to the left of the decimal point. This can result in an incompatibility if an application has a reliance on MySQL allowing "too-large" values.

The SQL standard requires that the precision of `NUMERIC(M,D)` be exactly M digits. For `DECIMAL(M,D)`, the standard requires a precision of at least M digits but allows more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same and both have a precision of exactly M digits.

Summary of incompatibilities:

The following list summarizes the incompatibilities that result from changes to `DECIMAL` column and value handling. You can use it as guide when porting older applications for use with MySQL 5.0.3 and up.

- For `DECIMAL(M,D)`, the maximum M is 64, not 254.
- Calculations involving exact-value decimal numbers are accurate to 64 digits. This is fewer than the maximum number of digits allowed before MySQL 5.0.3 (254 digits), but the exact-value precision is greater. Calculations formerly were done with double-precision floating-point, which has a precision of 52 bits (about 15 decimal digits).
- The non-standard MySQL extension to the upper range of `DECIMAL` columns no longer is supported.
- Leading '+' and '0' characters are not stored.

23.3. Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or `integer`), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (Without strict mode, truncation for `INSERT` is allowable.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 64 digits. ("Exact" is subject to the limits of what can be represented in binary. $1.0/3.0$ can be represented as $.333\dots$ to a finite number of digits, not as "exactly one-third," so $(1.0/3.0)*3.0$ does not evaluate to "exactly 1.0.")
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See Section 1.7.2, "Selecting SQL Modes".) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode and `ERROR_FOR_DIVISION_BY_ZERO`:

```
mysql> SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (`DECIMAL` or integer), it should be inserted with its exact value if it is within the column range.

If the value has too many digits in the fractional part, rounding occurs and a warning is generated. Rounding is done as described in "Rounding Behavior."

If the value has too many digits in the integer part, it is too large and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

By default, division by zero produces a result of `NULL` and no warning. With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes:

<code>sql_mode</code> Value	Result
<code>''</code>	No warning, no error, <code>i</code> is set to NULL
<code>strict</code>	No warning, no error, <code>i</code> is set to NULL
<code>ERROR_FOR_DIVISION_BY_ZERO</code>	Warning, no error, <code>i</code> is set to NULL
<code>strict,ERROR_FOR_DIVISION_BY_ZERO</code>	Error, no row inserted

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has non-numeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.
- A string that begins with a number can be converted, but there is truncation of the trailing non-numeric part. This produces an error in strict mode, or a warning otherwise.

23.4. Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into `DECIMAL` columns.

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the "round half up" rule: A value with a fractional part of `.5` or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than `.5` is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the "round to nearest even" rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For inserts into a `DECIMAL` column, the target is an exact data type, so rounding uses "round half up," regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 2

mysql> SELECT d FROM t;
+-----+
| d     |
+-----+
```

```
+-----+
| 3     |
| 3     |
+-----+
```

23.5. Precision Math Examples

This section provides some examples that show how precision math improves query results in MySQL 5 compared to older versions.

Example 1. Numbers are used with their exact value as given when possible.

Before MySQL 5.0.3, numbers that are treated as floating-point values produce inexact results:

```
mysql> SELECT .1 + .2 = .3;
+-----+
| .1 + .2 = .3 |
+-----+
|                0 |
+-----+
```

As of MySQL 5.0.3, numbers are used as given when possible:

```
mysql> SELECT .1 + .2 = .3;
+-----+
| .1 + .2 = .3 |
+-----+
|                1 |
+-----+
```

However, for floating-point values, inexactness still occurs:

```
mysql> SELECT .1E0 + .2E0 = .3E0;
+-----+
| .1E0 + .2E0 = .3E0 |
+-----+
|                0 |
+-----+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds .0001 to a variable 1000 times.

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;
```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```
+-----+-----+
| d      | f      |
+-----+-----+
```

```
+-----+-----+
| 1.0000 | 0.999999999999991 |
+-----+-----+
```

Example 2. Multiplication is done with the scale required by standard SQL. That is, for two numbers $X1$ and $X2$ that have scale $S1$ and $S2$, the scale of the result is $S1 + S2$.

Before MySQL 5.0.3, this is what happens:

```
mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
|          0.00 |
+-----+
```

The displayed value is incorrect. The value was calculated correctly in this case, but not displayed to the required scale. To see that the calculated value actually was .0001, try this:

```
mysql> SELECT .01 * .01 + .0000;
+-----+
| .01 * .01 + .0000 |
+-----+
|                0.0001 |
+-----+
```

As of MySQL 5.0.3, the displayed scale is correct:

```
mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
| 0.0001 |
+-----+
```

Example 3. Rounding behavior is well-defined.

Before MySQL 5.0.3, rounding behavior (for example, with the `ROUND()` function) is dependent on the implementation of the underlying C library. This results in inconsistencies from platform to platform. For example, you might get a different value on Windows than on Linux, or a different value on x86 machines than on PowerPC machines.

As of MySQL 5.0.3, rounding happens like this:

Rounding for `DECIMAL` columns and exact-valued numbers uses the "round half up" rule. Values with a fractional part of .5 or greater are rounded away from zero to the nearest integer, as shown here:

```
mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+-----+
| 3          | -3          |
+-----+-----+
```

Rounding for floating-point values still uses the C library, which on many systems uses the "round to nearest even" rule. Values with any fractional part are rounded to the nearest even integer:

```
mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+-----+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+-----+
```

```
|          2 |          -2 |
+-----+-----+
```

Example 4. For inserts into tables, a value that is too large results in overflow and causes an error, not truncation to a legal value. (This requires strict mode.)

Before MySQL 5.0.2, truncation to a legal value occurs:

```
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.01 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| 127  |
+-----+
1 row in set (0.00 sec)
```

As of MySQL 5.0.2, overflow occurs if strict mode is in effect:

```
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.10 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

Example 5. For inserts into tables, division by zero causes an error, not a result of NULL. (This requires strict mode and `ERROR_FOR_DIVISION_BY_ZERO`.)

Before MySQL 5.0.2, division by zero has a result of NULL:

```
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.06 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| NULL  |
+-----+
1 row in set (0.01 sec)
```

As of MySQL 5.0.2, division by zero is an error if the proper SQL modes are in effect:

```
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
```

ERROR 1365 (22012): Division by 0

```
mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

Example 6. In MySQL 4, exact-value and approximate-value literals both are converted to double-precision floating-point values:

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
```

```
mysql> DESCRIBE t;
```

Field	Type	Null	Key	Default	Extra
a	double(3,1)			0.0	
b	double			0	

In MySQL 5, the approximate-value literal still is converted to floating-point, but the exact-value literal is handled as DECIMAL:

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
```

```
mysql> DESCRIBE t;
```

Field	Type	Null	Key	Default	Extra
a	decimal(3,1)	NO		0.0	
b	double	NO		0	

Example 7. If the argument to an aggregate function is an exact numeric type, the result should be as well, with a scale at least that of the argument. The result should not always be a double.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

Result before MySQL 5.0.3:

```
mysql> DESCRIBE y;
```

Field	Type	Null	Key	Default	Extra
AVG(i)	double(17,4)	YES		NULL	
AVG(d)	double(17,4)	YES		NULL	
AVG(f)	double	YES		NULL	

The result is a double no matter the argument type.

Result as of MySQL 5.0.3:

```
mysql> DESCRIBE y;
```

Field	Type	Null	Key	Default	Extra
AVG(i)	decimal(64,0)	YES		NULL	
AVG(d)	decimal(64,0)	YES		NULL	
AVG(f)	double	YES		NULL	

The result is a double only for the floating-point argument. The result is an exact type for exact type arguments.

Chapter 24. MySQL APIs

This chapter describes the APIs available for MySQL, where to get them, and how to use them. The C API is the most extensively covered, because it was developed by the MySQL team, and is the basis for most of the other APIs.

24.1. MySQL Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

- `msql2mysql`

A shell script that converts mSQL programs to MySQL. It doesn't handle every case, but it gives a good start when converting.

- `mysql_config`

A shell script that produces the option values needed when compiling MySQL programs.

24.1.1. `msql2mysql`, Convert mSQL Programs for Use with MySQL

Initially, the MySQL C API was developed to be very similar to that for the mSQL database system. Because of this, mSQL programs often can be converted relatively easily for use with MySQL by changing the names of the C API functions.

The `msql2mysql` utility performs the conversion of mSQL C API function calls to their MySQL equivalents. `msql2mysql` converts the input file in place, so make a copy of the original before converting it. For example, use `msql2mysql` like this:

```
shell> cp client-prog.c client-prog.c.orig
shell> msql2mysql client-prog.c
client-prog.c converted
```

Then examine `client-prog.c` and make any post-conversion revisions that may be necessary.

`msql2mysql` uses the `replace` utility to make the function name substitutions. See Section 8.13, “The `replace` String-Replacement Utility”.

24.1.2. `mysql_config`, Get compile options for compiling clients

`mysql_config` provides you with useful information for compiling your MySQL client and connecting it to MySQL.

`mysql_config` supports the following options:

- `--cflags`

Compiler flags to find include files and critical compiler flags and defines used when compiling the `libmysqlclient` library.

- `--include`

Compiler options to find MySQL include files. (Note that normally you would use `--cflags` instead of this option.)

- `--libmysqld-libs`, `--embedded`

Libraries and options required to link with the MySQL embedded server.

- `--libs`

Libraries and options required to link with the MySQL client library.

- `--libs_r`

Libraries and options required to link with the thread-safe MySQL client library.

- `--port`

The default TCP/IP port number, defined when configuring MySQL.

- `--socket`

The default Unix socket file, defined when configuring MySQL.

- `--version`

Version number and version for the MySQL distribution.

If you invoke `mysql_config` with no options, it displays a list of all options that it supports, and their values:

```
shell> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
--cflags           [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
--include          [-I/usr/local/mysql/include/mysql]
--libs             [-L/usr/local/mysql/lib/mysql -lmysqlclient -lz
                  -lcrypt -lnsl -lm -L/usr/lib -lssl -lcrypto]
--libs_r          [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
                  -lpthread -lz -lcrypt -lnsl -lm -lpthread]
--socket          [/tmp/mysql.sock]
--port            [3306]
--version         [4.0.16]
--libmysqld-libs  [-L/usr/local/mysql/lib/mysql -lmysqld -lpthread -lz
                  -lcrypt -lnsl -lm -lpthread -lrt]
```

You can use `mysql_config` within a command line to include the value that it displays for a particular option. For example, to compile a MySQL client program, use `mysql_config` as follows:

```
CFG=/usr/local/mysql/bin/mysql_config
sh -c "gcc -o progname ` $CFG --cflags ` progname.c ` $CFG --libs `"
```

When you use `mysql_config` this way, be sure to invoke it within backtick (``) characters. That tells the shell to execute it and substitute its output into the surrounding command.

24.2. MySQL C API

The C API code is distributed with MySQL. It is included in the `mysqlclient` library and allows C programs to access a database.

Many of the clients in the MySQL source distribution are written in C. If you are looking for examples that demonstrate how to use the C API, take a look at these clients. You can find these in the

`clients` directory in the MySQL source distribution.

Most of the other client APIs (all except Connector/J) use the `mysqlclient` library to communicate with the MySQL server. This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs, because they are referenced from the library. See Chapter 8, *MySQL Client and Utility Programs*, for a list of these variables.

The client has a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (the maximum is 16MB). Because buffer sizes are increased only as demand warrants, simply increasing the default maximum limit does not in itself cause more resources to be used. This size check is mostly a check for erroneous queries and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each thread's communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have BLOB values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The client's default maximum is 16MB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` parameter when the server is started. See Section 7.5.2, "Tuning Server Parameters".

The MySQL server shrinks each communication buffer to `net_buffer_length` bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

For programming with threads, see Section 24.2.15, "How to Make a Threaded Client". For creating a standalone application which includes the "server" and "client" in the same program (and does not communicate with an external MySQL server), see Section 24.2.16, "libmysqld, the Embedded MySQL Server Library".

24.2.1. C API Data types

- `MYSQL`

This structure represents a handle to one database connection. It is used for almost all MySQL functions.

- `MYSQL_RES`

This structure represents the result of a query that returns rows (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`). The information returned from a query is called the *result set* in the remainder of this section.

- `MYSQL_ROW`

This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

- `MYSQL_FIELD`

This structure contains information about a field, such as the field's name, type, and size. Its members are described in more detail here. You may obtain the `MYSQL_FIELD` structures for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

- `MYSQL_FIELD_OFFSET`

This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

- `my_ulonglong`

The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of 0 to `1.84e19`.

On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

```
printf ("Number of rows: %lu\n", (unsigned long) mysql_num_rows(result));
```

The `MYSQL_FIELD` structure contains the members listed here:

- `char * name`

The name of the field, as a null-terminated string.

- `char * table`

The name of the table containing this field, if it isn't a calculated field. For calculated fields, the `table` value is an empty string.

- `char * def`

The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

- `enum enum_field_types type`

The type of the field. The `type` value may be one of the following:

Type Value	Type Description
<code>FIELD_TYPE_TINY</code>	TINYINT field
<code>FIELD_TYPE_SHORT</code>	SMALLINT field
<code>FIELD_TYPE_LONG</code>	INTEGER field
<code>FIELD_TYPE_INT24</code>	MEDIUMINT field
<code>FIELD_TYPE_LONGLONG</code>	BIGINT field
<code>FIELD_TYPE_DECIMAL</code>	DECIMAL or NUMERIC field
<code>FIELD_TYPE_FLOAT</code>	FLOAT field
<code>FIELD_TYPE_DOUBLE</code>	DOUBLE or REAL field
<code>FIELD_TYPE_TIMESTAMP</code>	TIMESTAMP field
<code>FIELD_TYPE_DATE</code>	DATE field
<code>FIELD_TYPE_TIME</code>	TIME field
<code>FIELD_TYPE_DATETIME</code>	DATETIME field
<code>FIELD_TYPE_YEAR</code>	YEAR field
<code>FIELD_TYPE_STRING</code>	CHAR field
<code>FIELD_TYPE_VAR_STRING</code>	VARCHAR field
<code>FIELD_TYPE_BLOB</code>	BLOB or TEXT field (use <code>max_length</code> to determine the maximum length)

FIELD_TYPE_SET	SET field
FIELD_TYPE_ENUM	ENUM field
FIELD_TYPE_NULL	NULL-type field
FIELD_TYPE_CHAR	Deprecated; use FIELD_TYPE_TINY instead

You can use the `IS_NUM()` macro to test whether a field has a numeric type. Pass the type value to `IS_NUM()` and it evaluates to `TRUE` if the field is numeric:

```
if (IS_NUM(field->type))
    printf("Field is numeric\n");
```

- unsigned int length

The width of the field, as specified in the table definition.

- unsigned int max_length

The maximum width of the field for the result set (the length of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

- unsigned int flags

Different bit-flags for the field. The `flags` value may have zero or more of the following bits set:

Flag Value	Flag Description
NOT_NULL_FLAG	Field can't be NULL
PRI_KEY_FLAG	Field is part of a primary key
UNIQUE_KEY_FLAG	Field is part of a unique key
MULTIPLE_KEY_FLAG	Field is part of a non-unique key
UNSIGNED_FLAG	Field has the UNSIGNED attribute
ZEROFILL_FLAG	Field has the ZEROFILL attribute
BINARY_FLAG	Field has the BINARY attribute
AUTO_INCREMENT_FLAG	Field has the AUTO_INCREMENT attribute
ENUM_FLAG	Field is an ENUM (deprecated)
SET_FLAG	Field is a SET (deprecated)
BLOB_FLAG	Field is a BLOB or TEXT (deprecated)
TIMESTAMP_FLAG	Field is a TIMESTAMP (deprecated)

Use of the `BLOB_FLAG`, `ENUM_FLAG`, `SET_FLAG`, and `TIMESTAMP_FLAG` flags is deprecated because they indicate the type of a field rather than an attribute of its type. It is preferable to test `field->type` against `FIELD_TYPE_BLOB`, `FIELD_TYPE_ENUM`, `FIELD_TYPE_SET`, or `FIELD_TYPE_TIMESTAMP` instead.

The following example illustrates a typical use of the `flags` value:

```
if (field->flags & NOT_NULL_FLAG)
    printf("Field can't be null\n");
```

You may use the following convenience macros to determine the boolean status of the flags value:

Flag Status	Description
<code>IS_NOT_NULL(flags)</code>	True if this field is defined as NOT NULL
<code>IS_PRI_KEY(flags)</code>	True if this field is a primary key
<code>IS_BLOB(flags)</code>	True if this field is a BLOB or TEXT (deprecated; test <code>field->type</code> instead)

- unsigned int decimals

The number of decimals for numeric fields.

24.2.2. C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See Section 24.2.3, “C API Function Descriptions”.

Function	Description
<code>mysql_affected_rows()</code>	Returns the number of rows changed/deleted/inserted by the last UPDATE, DELETE, or INSERT query.
<code>mysql_change_user()</code>	Changes user and database on an open connection.
<code>mysql_charset_name()</code>	Returns the name of the default character set for the connection.
<code>mysql_close()</code>	Closes a server connection.
<code>mysql_connect()</code>	Connects to a MySQL server. This function is deprecated; use <code>mysql_real_connect()</code> instead.
<code>mysql_create_db()</code>	Creates a database. This function is deprecated; use the SQL statement CREATE DATABASE instead.
<code>mysql_data_seek()</code>	Seeks to an arbitrary row number in a query result set.
<code>mysql_debug()</code>	Does a DEBUG_PUSH with the given string.
<code>mysql_drop_db()</code>	Drops a database. This function is deprecated; use the SQL statement DROP DATABASE instead.
<code>mysql_dump_debug_info()</code>	Makes the server write debug information to the log.
<code>mysql_eof()</code>	Determines whether the last row of a result set has been read. This function is deprecated; <code>mysql_errno()</code> or <code>mysql_error()</code> may be used instead.
<code>mysql_errno()</code>	Returns the error number for the most recently invoked MySQL function.
<code>mysql_error()</code>	Returns the error message for the most recently invoked MySQL function.
<code>mysql_escape_string()</code>	Escapes special characters in a string for use in an SQL statement.
<code>mysql_fetch_field()</code>	Returns the type of the next table field.
<code>mysql_fetch_field_direct()</code>	Returns the type of a table field, given a field number.
<code>mysql_fetch_fields()</code>	Returns an array of all field structures.
<code>mysql_fetch_lengths()</code>	Returns the lengths of all columns in the current row.
<code>mysql_fetch_row()</code>	Fetches the next row from the result set.
<code>mysql_field_seek()</code>	Puts the column cursor on a specified column.
<code>mysql_field_count()</code>	Returns the number of result columns for the most recent state-

	ment.
mysql_field_tell()	Returns the position of the field cursor used for the last <code>mysql_fetch_field()</code> .
mysql_free_result()	Frees memory used by a result set.
mysql_get_client_info()	Returns client version information as a string.
mysql_get_client_version()	Returns client version information as an integer.
mysql_get_host_info()	Returns a string describing the connection.
mysql_get_server_version()	Returns version number of server as an integer (new in 4.1).
mysql_get_proto_info()	Returns the protocol version used by the connection.
mysql_get_server_info()	Returns the server version number.
mysql_info()	Returns information about the most recently executed query.
mysql_init()	Gets or initializes a MySQL structure.
mysql_insert_id()	Returns the ID generated for an <code>AUTO_INCREMENT</code> column by the previous query.
mysql_kill()	Kills a given thread.
mysql_library_end()	Finalize MySQL C API library.
mysql_library_init()	Initialize MySQL C API library.
mysql_list_dbs()	Returns database names matching a simple regular expression.
mysql_list_fields()	Returns field names matching a simple regular expression.
mysql_list_processes()	Returns a list of the current server threads.
mysql_list_tables()	Returns table names matching a simple regular expression.
mysql_num_fields()	Returns the number of columns in a result set.
mysql_num_rows()	Returns the number of rows in a result set.
mysql_options()	Sets connect options for <code>mysql_connect()</code> .
mysql_ping()	Checks whether the connection to the server is working, reconnecting as necessary.
mysql_query()	Executes an SQL query specified as a null-terminated string.
mysql_real_connect()	Connects to a MySQL server.
mysql_real_escape_string()	Escapes special characters in a string for use in an SQL statement, taking into account the current charset of the connection.
mysql_real_query()	Executes an SQL query specified as a counted string.
mysql_reload()	Tells the server to reload the grant tables.
mysql_row_seek()	Seeks to a row offset in a result set, using value returned from <code>mysql_row_tell()</code> .
mysql_row_tell()	Returns the row cursor position.
mysql_select_db()	Selects a database.
mysql_server_end()	Finalize embedded server library.
mysql_server_init()	Initialize embedded server library.
mysql_set_server_option()	Sets an option for the connection (like <code>multi-statements</code>).
mysql_sqlstate()	Returns the SQLSTATE error code for the last error.
mysql_shutdown()	Shuts down the database server.
mysql_stat()	Returns the server status as a string.
mysql_store_result()	Retrieves a complete result set to the client.
mysql_thread_id()	Returns the current thread ID.
mysql_thread_safe()	Returns 1 if the clients are compiled as thread-safe.
mysql_use_result()	Initiates a row-by-row result set retrieval.

mysql_warning_count()	Returns the warning count for the previous SQL statement.
mysql_commit()	Commits the transaction.
mysql_rollback()	Rolls back the transaction.
mysql_autocommit()	Toggles autocommit mode on/off.
mysql_more_results()	Checks whether any more results exist.
mysql_next_result()	Returns/initiates the next result in multiple-statement executions.

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling `mysql_library_init()`. The library can be either the `mysqlclient` C client library or the `mysqld` embedded server library, depending on whether the application was linked with the `-libmysqlclient` or `-libmysqld` flag.
2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling `mysql_real_connect()`.
3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)
4. Close the connection to the MySQL server by calling `mysql_close()`.
5. End use of the MySQL library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you don't call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

`mysql_library_init()` and `mysql_library_end()` are available as of MySQL 4.1.10 and 5.0.3. These actually are `#define` symbols that make them equivalent to `mysql_server_init()` and `mysql_server_end()`, but the names more clearly indicate that they should be called when beginning and ending use of a MySQL library no matter whether the application uses the `mysqlclient` or `mysqld` library. For older versions of MySQL, you can call `mysql_server_init()` and `mysql_server_end()` instead.

If you like, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the hostname, username, and password). Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of 1 in versions of the API strictly older than 5.0.3, of 0 in newer versions. A value of 1 for this flag indicates, in the event that a query cannot be performed because of a lost connection, to try reconnecting to the server before giving up. When you are done with the connection, call `mysql_close()` to terminate it.

While a connection is active, the client may send SQL queries to the server using `mysql_query()` or `mysql_real_query()`. The difference between the two is that `mysql_query()` expects the query to be specified as a null-terminated string whereas `mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-SELECT query (for example, INSERT, UPDATE, DELETE), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For SELECT queries, you retrieve the selected rows as a result set. (Note that some statements are

SELECT-like in that they return rows. These include SHOW, DESCRIBE, and EXPLAIN. They should be treated the same way as SELECT statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`, `mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.

The two retrieval mechanisms are complementary. Client programs should choose the approach that is most appropriate for their requirements. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you don't have random access to rows within the result set (you can only access rows sequentially), and you don't know how many rows are in the result set until you have retrieved them all. Furthermore, you **must** retrieve all the rows even if you determine in mid-retrieval that you've found the information you were looking for.

The API makes it possible for clients to respond appropriately to queries (retrieving rows only as necessary) without knowing whether or not the query is a SELECT. You can do this by calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the query was a SELECT and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the query returned no data (indicating that it was an INSERT, UPDATE, DELETE, etc.), and was not expected to return rows. If `mysql_field_count()` is non-zero, the query should have returned rows, but didn't. This indicates that the query was a SELECT that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` allow you to obtain information about the fields that make up the result set (the number of fields, their names and types, etc.). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, allowing you to determine when an error occurred and what it was.

24.2.3. C API Function Descriptions

In the descriptions here, a parameter or return value of NULL means NULL in the sense of the C pro-

gramming language, not a MySQL NULL value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-NULL value to indicate success or a NULL value to indicate an error, and functions returning an integer return zero to indicate success or non-zero to indicate an error. Note that "non-zero" means just that. Unless the function description says otherwise, do not test against a value other than zero:

```
if (result)                /* correct */
    ... error ...

if (result < 0)            /* incorrect */
    ... error ...

if (result == -1)         /* incorrect */
    ... error ...
```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

24.2.3.1. `mysql_affected_rows()`

```
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

Description

Returns the number of rows changed by the last UPDATE, deleted by the last DELETE or inserted by the last INSERT statement. May be called immediately after `mysql_query()` for UPDATE, DELETE, or INSERT statements. For SELECT statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an UPDATE statement, no rows matched the WHERE clause in the query or that no query has yet been executed. #1 indicates that the query returned an error or that, for a SELECT query, `mysql_affected_rows()` was called prior to calling `mysql_store_result()`. Because `mysql_affected_rows()` returns an unsigned value, you can check for #1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

Errors

None.

Example

```
mysql_query(&mysql, "UPDATE products SET cost=cost*1.25 WHERE group=10");
printf("%ld products updated", (long) mysql_affected_rows(&mysql));
```

If you specify the flag `CLIENT_FOUND_ROWS` when connecting to **mysqld**, `mysql_affected_rows()` returns the number of rows matched by the WHERE statement for UPDATE statements.

Note that when you use a REPLACE command, `mysql_affected_rows()` returns 2 if the new row replaced an old row. This is because in this case one row was inserted after the duplicate was deleted.

If you use `INSERT ... ON DUPLICATE KEY UPDATE` to insert a row, `mysql_affected_rows()` returns 1 if the row is inserted as a new row and 2 if an existing row is updated.

24.2.3.2. `mysql_change_user()`

```
my_bool mysql_change_user(MYSQL *mysql, const char *user, const
char *password, const char *db)
```

Description

Changes the user and causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

This function was introduced in MySQL 3.23.3.

`mysql_change_user()` fails if the connected user cannot be authenticated or doesn't have permission to use the database. In this case the user and database are not changed

The `db` parameter may be set to `NULL` if you don't want to have a default database.

Starting from MySQL 4.0.6 this command always performs a `ROLLBACK` of any active transactions, closes all temporary tables, unlocks all locked tables and resets the state as if one had done a new connect. This happens even if the user didn't change.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

The same that you can get from `mysql_real_connect()`.

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.
- `ER_UNKNOWN_COM_ERROR`
The MySQL server doesn't implement this command (probably an old server).
- `ER_ACCESS_DENIED_ERROR`
The user or password was wrong.
- `ER_BAD_DB_ERROR`
The database didn't exist.
- `ER_DBACCESS_DENIED_ERROR`
The user did not have access rights to the database.
- `ER_WRONG_DB_NAME`

The database name was too long.

Example

```
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
    fprintf(stderr, "Failed to change user. Error: %s\n",
            mysql_error(&mysql));
}
```

24.2.3.3. mysql_character_set_name()

```
const char *mysql_character_set_name(MYSQL *mysql)
```

Description

Returns the default character set for the current connection.

Return Values

The default character set

Errors

None.

24.2.3.4. mysql_close()

```
void mysql_close(MYSQL *mysql)
```

Description

Closes a previously opened connection. `mysql_close()` also deallocates the connection handle pointed to by `mysql` if the handle was allocated automatically by `mysql_init()` or `mysql_connect()`.

Return Values

None.

Errors

None.

24.2.3.5. mysql_connect()

```
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char
*user, const char *passwd)
```

Description

This function is deprecated. It is preferable to use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case the C API allocates memory for the connection structure automatically and frees it when

you call `mysql_close()`. The disadvantage of this approach is that you can't retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid MySQL pointer.)

Return Values

Same as for `mysql_real_connect()`.

Errors

Same as for `mysql_real_connect()`.

24.2.3.6. `mysql_create_db()`

```
int mysql_create_db(MYSQL *mysql, const char *db)
```

Description

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL CREATE DATABASE statement instead.

Return Values

Zero if the database was created successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

Example

```
if(mysql_create_db(&mysql, "my_database"))
{
    fprintf(stderr, "Failed to create new database. Error: %s\n",
            mysql_error(&mysql));
}
```

24.2.3.7. `mysql_data_seek()`

```
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

Description

Seeks to an arbitrary row in a query result set. The offset value is a row number and should be in the range from 0 to `mysql_num_rows(result)-1`.

This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

Return Values

None.

Errors

None.

24.2.3.8. `mysql_debug()`

```
void mysql_debug(const char *debug)
```

Description

Does a `DEBUG_PUSH` with the given string. `mysql_debug()` uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See Section E.1, “Debugging a MySQL Server”. See Section E.2, “Debugging a MySQL Client”.

Return Values

None.

Errors

None.

Example

The call shown here causes the client library to generate a trace file in `/tmp/client.trace` on the client machine:

```
mysql_debug("d:t:0,/tmp/client.trace");
```

24.2.3.9. `mysql_drop_db()`

```
int mysql_drop_db(MYSQL *mysql, const char *db)
```

Description

Drops the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `DROP DATABASE` statement instead.

Return Values

Zero if the database was dropped successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.

- CR_SERVER_LOST

The connection to the server was lost during the query.

- CR_UNKNOWN_ERROR

An unknown error occurred.

Example

```
if(mysql_drop_db(&mysql, "my_database"))
    fprintf(stderr, "Failed to drop the database: Error: %s\n",
           mysql_error(&mysql));
```

24.2.3.10. `mysql_dump_debug_info()`

```
int mysql_dump_debug_info(MYSQL *mysql)
```

Description

Instructs the server to write some debug information to the log. For this to work, the connected user must have the SUPER privilege.

Return Values

Zero if the command was successful. Non-zero if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC

Commands were executed in an improper order.

- CR_SERVER_GONE_ERROR

The MySQL server has gone away.

- CR_SERVER_LOST

The connection to the server was lost during the query.

- CR_UNKNOWN_ERROR

An unknown error occurred.

24.2.3.11. `mysql_eof()`

```
my_bool mysql_eof(MYSQL_RES *result)
```

Description

This function is deprecated. `mysql_errno()` or `mysql_error()` may be used instead.

`mysql_eof()` determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to `mysql_store_result()`, the client receives the entire set in one operation. In this case, a NULL return from `mysql_fetch_row()` always means the end of the result set has been reached and it is unnecessary to call `mysql_eof()`. When used with `mysql_store_result()`, `mysql_eof()` always returns true.

On the other hand, if you use `mysql_use_result()` to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call `mysql_fetch_row()` repeatedly. Because an error may occur on the connection during this process, a NULL return value from `mysql_fetch_row()` does not necessarily mean the end of the result set was reached normally. In this case, you can use `mysql_eof()` to determine what happened. `mysql_eof()` returns a non-zero value if the end of the result set was reached and zero if an error occurred.

Historically, `mysql_eof()` predates the standard MySQL error functions `mysql_errno()` and `mysql_error()`. Because those error functions provide the same information, their use is preferred over `mysql_eof()`, which is deprecated. (In fact, they provide more information, because `mysql_eof()` returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

Return Values

Zero if no error occurred. Non-zero if the end of the result set has been reached.

Errors

None.

Example

The following example shows how you might use `mysql_eof()`:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

24.2.3.12. `mysql_errno()`

```
unsigned int mysql_errno(MYSQL *mysql)
```

Description

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. In the MySQL source distribution you can find a complete list of error messages and error numbers in the file `Docs/mysqld_error.txt`. The server error codes also are listed at Chapter 26, *Error Handling in MySQL*.

Note that some functions like `mysql_fetch_row()` don't set `mysql_errno()` if they suc-

ceed.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_errno()` if they succeed.

Return Values

An error code value for the last `mysql_xxx()` call, if it failed. zero means no error occurred.

Errors

None.

24.2.3.13. `mysql_error()`

```
const char *mysql_error(MYSQL *mysql)
```

Description

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function didn't fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_errno()`, the following two tests are equivalent:

```
if(mysql_errno(&mysql))
{
    // an error occurred
}

if(mysql_error(&mysql)[0] != '\0')
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently you can choose error messages in several different languages. See Section 5.9.2, “Setting the Error Message Language”.

Return Values

A null-terminated character string that describes the error. An empty string if no error occurred.

Errors

None.

24.2.3.14. `mysql_escape_string()`

You should use `mysql_real_escape_string()` instead!

This function is identical to `mysql_real_escape_string()` except that `mysql_real_escape_string()` takes a connection handler as its first argument and escapes the string according to the current character set. `mysql_escape_string()` does not take a connection argument and does not respect the current charset setting.

24.2.3.15. `mysql_fetch_field()`

```
MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)
```

Description

Returns the definition of one column of a result set as a `MYSQL_FIELD` structure. Call this function repeatedly to retrieve information about all columns in the result set. `mysql_fetch_field()` returns `NULL` when no more fields are left.

`mysql_fetch_field()` is reset to return information about the first field each time you execute a new `SELECT` query. The field returned by `mysql_fetch_field()` is also affected by calls to `mysql_field_seek()`.

If you've called `mysql_query()` to perform a `SELECT` on a table but have not called `mysql_store_result()`, MySQL returns the default blob length (8KB) if you call `mysql_fetch_field()` to ask for the length of a BLOB field. (The 8KB size is chosen because MySQL doesn't know the maximum length for the BLOB. This should be made configurable sometime.) Once you've retrieved the result set, `field->max_length` contains the length of the largest value for this column in the specific query.

Return Values

The `MYSQL_FIELD` structure for the current column. `NULL` if no columns are left.

Errors

None.

Example

```
MYSQL_FIELD *field;

while((field = mysql_fetch_field(result)))
{
    printf("field name %s\n", field->name);
}
```

24.2.3.16. `mysql_fetch_fields()`

```
MYSQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)
```

Description

Returns an array of all `MYSQL_FIELD` structures for a result set. Each structure provides the field definition for one column of the result set.

Return Values

An array of `MYSQL_FIELD` structures for all columns of a result set.

Errors

None.

Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *fields;

num_fields = mysql_num_fields(result);
fields = mysql_fetch_fields(result);
for(i = 0; i < num_fields; i++)
{
    printf("Field %u is %s\n", i, fields[i].name);
}
```

24.2.3.17. `mysql_fetch_field_direct()`

```
MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned
int fieldnr)
```

Description

Given a field number `fieldnr` for a column within a result set, returns that column's field definition as a `MYSQL_FIELD` structure. You may use this function to retrieve the definition for an arbitrary column. The value of `fieldnr` should be in the range from 0 to `mysql_num_fields(result)-1`.

Return Values

The `MYSQL_FIELD` structure for the specified column.

Errors

None.

Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *field;

num_fields = mysql_num_fields(result);
for(i = 0; i < num_fields; i++)
{
    field = mysql_fetch_field_direct(result, i);
    printf("Field %u is %s\n", i, field->name);
}
```

24.2.3.18. `mysql_fetch_lengths()`

```
unsigned long *mysql_fetch_lengths(MYSQL_RES *result)
```

Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling `strlen()`. In addition, if the result set contains binary data, you **must** use this function to determine the size of the data, because `strlen()` returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing NULL values is zero. To see how to distinguish these two cases, see the description for `mysql_fetch_row()`.

Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null characters). NULL if an error occurred.

Errors

`mysql_fetch_lengths()` is valid only for the current row of the result set. It returns NULL if you call it before calling `mysql_fetch_row()` or after retrieving all rows in the result.

Example

```
MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
```

```
unsigned int i;

row = mysql_fetch_row(result);
if (row)
{
    num_fields = mysql_num_fields(result);
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("Column %u is %lu bytes in length.\n", i, lengths[i]);
    }
}
```

24.2.3.19. `mysql_fetch_row()`

`MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)`

Description

Retrieves the next row of a result set. When used after `mysql_store_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve. When used after `mysql_use_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve or if an error occurred.

The number of values in the row is given by `mysql_num_fields(result)`. If `row` holds the return value from a call to `mysql_fetch_row()`, pointers to the values are accessed as `row[0]` to `row[mysql_num_fields(result)-1]`. `NULL` values in the row are indicated by `NULL` pointers.

The lengths of the field values in the row may be obtained by calling `mysql_fetch_lengths()`. Empty fields and fields containing `NULL` both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is `NULL`, the field is `NULL`; otherwise, the field is empty.

Return Values

A `MYSQL_ROW` structure for the next row. `NULL` if there are no more rows to retrieve or if an error occurred.

Errors

Note that error is not reset between calls to `mysql_fetch_row()`

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

Example

```
MYSQL_ROW row;
unsigned int num_fields;
unsigned int i;

num_fields = mysql_num_fields(result);
while ((row = mysql_fetch_row(result)))
{
    unsigned long *lengths;
    lengths = mysql_fetch_lengths(result);
```

```
    for(i = 0; i < num_fields; i++)
    {
        printf("[%.*s] ", (int) lengths[i], row[i] ? row[i] : "NULL");
    }
    printf("\n");
}
```

24.2.3.20. `mysql_field_count()`

```
unsigned int mysql_field_count(MYSQL *mysql)
```

If you are using a version of MySQL earlier than Version 3.22.24, you should use `unsigned int mysql_num_fields(MYSQL *mysql)` instead.

Description

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when `mysql_store_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a non-empty result. This allows the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See Section 24.2.13.1, “Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success”.

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if(mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
        else // mysql_store_result() should have returned data
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
    }
}
```

```
}  
}
```

An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a `SELECT`.

24.2.3.21. `mysql_field_seek()`

```
MYSQL_FIELD_OFFSET mysql_field_seek(MYSQL_RES *result,  
MYSQL_FIELD_OFFSET offset)
```

Description

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.

To seek to the beginning of a row, pass an `offset` value of zero.

Return Values

The previous value of the field cursor.

Errors

None.

24.2.3.22. `mysql_field_tell()`

```
MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)
```

Description

Returns the position of the field cursor used for the last `mysql_fetch_field()`. This value can be used as an argument to `mysql_field_seek()`.

Return Values

The current offset of the field cursor.

Errors

None.

24.2.3.23. `mysql_free_result()`

```
void mysql_free_result(MYSQL_RES *result)
```

Description

Frees the memory allocated for a result set by `mysql_store_result()`, `mysql_use_result()`, `mysql_list_dbs()`, etc. When you are done with a result set, you must free the memory it uses by calling `mysql_free_result()`.

Do not attempt to access a result set after freeing it.

Return Values

None.

Errors

None.

24.2.3.24. `mysql_get_client_info()`

```
char *mysql_get_client_info(void)
```

Description

Returns a string that represents the client library version.

Return Values

A character string that represents the MySQL client library version.

Errors

None.

24.2.3.25. `mysql_get_client_version()`

```
unsigned long mysql_get_client_version(void)
```

Description

Returns an integer that represents the client library version. The value has the format `XYZZ` where `X` is the major version, `YY` is the release level, and `ZZ` is the version number within the release level. For example, a value of `40102` represents a client library version of `4.1.2`.

This function was added in MySQL 4.0.16.

Return Values

An integer that represents the MySQL client library version.

Errors

None.

24.2.3.26. `mysql_get_host_info()`

```
char *mysql_get_host_info(MYSQL *mysql)
```

Description

Returns a string describing the type of connection in use, including the server hostname.

Return Values

A character string representing the server hostname and the connection type.

Errors

None.

24.2.3.27. `mysql_get_proto_info()`

```
unsigned int mysql_get_proto_info(MYSQL *mysql)
```

Description

Returns the protocol version used by current connection.

Return Values

An unsigned integer representing the protocol version used by the current connection.

Errors

None.

24.2.3.28. `mysql_get_server_info()`

```
char *mysql_get_server_info(MYSQL *mysql)
```

Description

Returns a string that represents the server version number.

Return Values

A character string that represents the server version number.

Errors

None.

24.2.3.29. `mysql_get_server_version()`

```
unsigned long mysql_get_server_version(MYSQL *mysql)
```

Description

Returns the version number of the server as an integer.

This function was added in MySQL 4.1.0.

Return Values

A number that represents the MySQL server version in this format:

```
major_version*10000 + minor_version *100 + sub_version
```

For example, 4.1.2 is returned as 40102.

This function is useful in client programs for quickly determining whether some version-specific server capability exists.

Errors

None.

24.2.3.30. `mysql_hex_string()`

```
unsigned long mysql_hex_string(char *to, const char *from, unsigned  
long length)
```

Description

This function is used to create a legal SQL string that you can use in a SQL statement. See Section 9.1.1, “Strings”.

The string in `from` is encoded to hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in `to` and a terminating null byte is appended.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. When `mysql_hex_string()` returns, the contents of `to` is a

null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

The return value can be placed into an SQL statement using either `0xvalue` or `X'value'` format. However, the return value does not include the `0x` or `X'` . . . '. The caller must supply whichever of those is desired.

`mysql_hex_string()` was added in MySQL 4.0.23 and 4.1.8.

Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
end = strmov(end,"0x");
end += mysql_hex_string(end,"What's this",11);
end = strmov(end,"");
end += mysql_hex_string(end,"binary data: \0\r\n",16);
*end++ = '\0';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
            mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

Return Values

The length of the value placed into `to`, not including the terminating null character.

Errors

None.

24.2.3.31. `mysql_info()`

```
char *mysql_info(MYSQL *mysql)
```

Description

Retrieves a string providing information about the most recently executed query, but only for the statements listed here. For other statements, `mysql_info()` returns `NULL`. The format of the string varies depending on the type of query, as described here. The numbers are illustrative only; the string contains values appropriate for the query.

- `INSERT INTO ... SELECT ...`
String format: Records: 100 Duplicates: 0 Warnings: 0
- `INSERT INTO ... VALUES (...),(...),(...)...`
String format: Records: 3 Duplicates: 0 Warnings: 0
- `LOAD DATA INFILE ...`
String format: Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
- `ALTER TABLE`
String format: Records: 3 Duplicates: 0 Warnings: 0

- UPDATE

String format: Rows matched: 40 Changed: 40 Warnings: 0

Note that `mysql_info()` returns a non-NULL value for `INSERT ... VALUES` only for the multiple-row form of the statement (that is, only if multiple value lists are specified).

Return Values

A character string representing additional information about the most recently executed query. NULL if no information is available for the query.

Errors

None.

24.2.3.32. `mysql_init()`

```
MYSQL *mysql_init(MYSQL *mysql)
```

Description

Allocates or initializes a MYSQL object suitable for `mysql_real_connect()`. If `mysql` is a NULL pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If `mysql_init()` allocates a new object, it is freed when `mysql_close()` is called to close the connection.

Return Values

An initialized `MYSQL*` handle. NULL if there was insufficient memory to allocate a new object.

Errors

In case of insufficient memory, NULL is returned.

24.2.3.33. `mysql_insert_id()`

```
my_ulonglong mysql_insert_id(MYSQL *mysql)
```

Description

Returns the value generated for an `AUTO_INCREMENT` column by the previous `INSERT` or `UPDATE` statement. Use this function after you have performed an `INSERT` statement into a table that contains an `AUTO_INCREMENT` field.

More precisely, `mysql_insert_id()` is updated under these conditions:

- `INSERT` statements that store a value into an `AUTO_INCREMENT` column. This is true whether the value is automatically generated by storing the special values `NULL` or `0` into the column, or is an explicit non-special value.
- In the case of a multiple-row `INSERT` statement, `mysql_insert_id()` returns the **first** automatically generated `AUTO_INCREMENT` value; if no such value is generated, it returns the last **last** explicit value inserted into the `AUTO_INCREMENT` column.
- `INSERT` statements that generate an `AUTO_INCREMENT` value by inserting `LAST_INSERT_ID(expr)` into any column.
- `INSERT` statements that generate an `AUTO_INCREMENT` value by updating any column to `LAST_INSERT_ID(expr)`.

- The value of `mysql_insert_id()` is not affected by statements such as `SELECT` that return a result set.
- If the previous statement returned an error, the value of `mysql_insert_id()` is undefined.

Note that `mysql_insert_id()` returns 0 if the previous statement does not use an `AUTO_INCREMENT` value. If you need to save the value for later, be sure to call `mysql_insert_id()` immediately after the statement that generates the value.

The value of `mysql_insert_id()` is affected only by statements issued within the current client connection. It is not affected by statements issued by other clients.

See Section 12.8.3, “Information Functions”.

Also note that the value of the SQL `LAST_INSERT_ID()` function always contains the most recently generated `AUTO_INCREMENT` value, and is not reset between statements because the value of that function is maintained in the server. Another difference is that `LAST_INSERT_ID()` is not updated if you set an `AUTO_INCREMENT` column to a specific non-special value.

The reason for the difference between `LAST_INSERT_ID()` and `mysql_insert_id()` is that `LAST_INSERT_ID()` is made easy to use in scripts while `mysql_insert_id()` tries to provide a little more exact information of what happens to the `AUTO_INCREMENT` column.

Return Values

Described in the preceding discussion.

Errors

None.

24.2.3.34. `mysql_kill()`

```
int mysql_kill(MYSQL *mysql, unsigned long pid)
```

Description

Asks the server to kill the thread specified by `pid`.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.35. `mysql_library_init()`

```
int mysql_library_init(int argc, char **argv, char **groups)
```

Description

This is a synonym for the `mysql_server_init()` function. It was added in MySQL 4.1.10 and 5.0.3.

See Section 24.2.2, “C API Function Overview” for usage information.

24.2.3.36. `mysql_library_end()`

```
void mysql_library_end(void)
```

Description

This is a synonym for the `mysql_server_end()` function. It was added in MySQL 4.1.10 and 5.0.3.

See Section 24.2.2, “C API Function Overview” for usage information.

24.2.3.37. `mysql_list_dbs()`

```
MYSQL_RES *mysql_list_dbs(MYSQL *mysql, const char *wild)
```

Description

Returns a result set consisting of database names on the server that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters `'%'` or `'_'`, or may be a `NULL` pointer to match all databases. Calling `mysql_list_dbs()` is similar to executing the query `SHOW databases [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.38. `mysql_list_fields()`

```
MYSQL_RES *mysql_list_fields(MYSQL *mysql, const char *table, const char *wild)
```

Description

Returns a result set consisting of field names in the given table that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters '%' or '_', or may be a NULL pointer to match all fields. Calling `mysql_list_fields()` is similar to executing the query `SHOW COLUMNS FROM tbl_name [LIKE wild]`.

Note that it's recommended that you use `SHOW COLUMNS FROM tbl_name` instead of `mysql_list_fields()`.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. NULL if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.39. `mysql_list_processes()`

```
MYSQL_RES *mysql_list_processes(MYSQL *mysql)
```

Description

Returns a result set describing the current server threads. This is the same kind of information as that reported by `mysqladmin processlist` or a `SHOW PROCESSLIST` query.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. NULL if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- CR_SERVER_LOST

The connection to the server was lost during the query.

- CR_UNKNOWN_ERROR

An unknown error occurred.

24.2.3.40. `mysql_list_tables()`

```
MYSQL_RES *mysql_list_tables(MYSQL *mysql, const char *wild)
```

Description

Returns a result set consisting of table names in the current database that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters '%' or '_', or may be a NULL pointer to match all tables. Calling `mysql_list_tables()` is similar to executing the query `SHOW tables [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

Return Values

A `MYSQL_RES` result set for success. NULL if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC

Commands were executed in an improper order.

- CR_SERVER_GONE_ERROR

The MySQL server has gone away.

- CR_SERVER_LOST

The connection to the server was lost during the query.

- CR_UNKNOWN_ERROR

An unknown error occurred.

24.2.3.41. `mysql_num_fields()`

```
unsigned int mysql_num_fields(MYSQL_RES *result)
```

Or:

```
unsigned int mysql_num_fields(MYSQL *mysql)
```

The second form doesn't work on MySQL 3.22.24 or newer. To pass a `MYSQL*` argument, you must use `unsigned int mysql_field_count(MYSQL *mysql)` instead.

Description

Returns the number of columns in a result set.

Note that you can get the number of columns either from a pointer to a result set or to a connection handle. You would use the connection handle if `mysql_store_result()` or `mysql_use_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a non-empty result. This allows the client program to take proper action without knowing whether or not the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

See Section 24.2.13.1, “Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success”.

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if (mysql_errno(&mysql))
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
        else if (mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
    }
}
```

An alternative (if you know that your query should have returned a result set) is to replace the `mysql_errno(&mysql)` call with a check whether `mysql_field_count(&mysql)` is `0`. This happens only if something went wrong.

24.2.3.42. `mysql_num_rows()`

```
my_ulonglong mysql_num_rows(MYSQL_RES *result)
```

Description

Returns the number of rows in the result set.

The use of `mysql_num_rows()` depends on whether you use `mysql_store_result()` or

`mysql_use_result()` to return the result set. If you use `mysql_store_result()`, `mysql_num_rows()` may be called immediately. If you use `mysql_use_result()`, `mysql_num_rows()` does not return the correct value until all the rows in the result set have been retrieved.

Return Values

The number of rows in the result set.

Errors

None.

24.2.3.43. `mysql_options()`

```
int mysql_options(MYSQL *mysql, enum mysql_option option, const
char *arg)
```

Description

Can be used to set extra connect options and affect behavior for a connection. This function may be called multiple times to set several options.

`mysql_options()` should be called after `mysql_init()` and before `mysql_connect()` or `mysql_real_connect()`.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, then `arg` should point to the value of the integer.

Possible option values:

Option	Argument Type	Function
<code>MYSQL_INIT_COMMAND</code>	<code>char *</code>	Command to execute when connecting to the MySQL server. Will automatically be re-executed when re-connecting.
<code>MYSQL_OPT_COMPRESS</code>	Not used	Use the compressed client/server protocol.
<code>MYSQL_OPT_CONNECT_TIMEOUT</code>	unsigned int *	Connect timeout in seconds.
<code>MYSQL_OPT_LOCAL_INFILE</code>	optional pointer to uint	If no pointer is given or if pointer points to an unsigned int != 0 the command <code>LOAD LOCAL INFILE</code> is enabled.
<code>MYSQL_OPT_NAMED_PIPE</code>	Not used	Use named pipes to connect to a MySQL server on NT.
<code>MYSQL_OPT_PROTOCOL</code>	unsigned int *	Type of protocol to use. Should be one of the enum values of <code>mysql_protocol_type</code> defined in <code>mysql.h</code> . New in 4.1.0.
<code>MYSQL_OPT_READ_TIMEOUT</code>	unsigned int *	Timeout for reads from server (works currently only on Windows on TCP/IP connections). New in 4.1.1.
<code>MYSQL_OPT_WRITE_TIMEOUT</code>	unsigned int *	Timeout for writes to server (works currently only on Windows on TCP/IP connections). New in 4.1.1.
<code>MYSQL_READ_DEFAULT_FILE</code>	<code>char *</code>	Read options from the named option file instead of from <code>my.cnf</code> .
<code>MYSQL_READ_DEFAULT_GROUP</code>	<code>char *</code>	Read options from the named group

		from my.cnf or the file specified with MySQL_READ_DEFAULT_FILE.
MYSQL_REPORT_DATA_TRUNCATION	my_bool *	Enable or disable reporting of data truncation errors for prepared statements via MySQL_BIND.error. (Default: disabled) New in 5.0.3.
MYSQL_SECURE_AUTH	my_bool*	Whether to connect to a server that does not support the new 4.1.1 password hashing. New in 4.1.1.
MYSQL_SET_CHARSET_DIR	char*	The pathname to the directory that contains character set definition files.
MYSQL_SET_CHARSET_NAME	char*	The name of the character set to use as the default character set.
MYSQL_SHARED_MEMORY_BASE_NAME	char*	Named of shared memory object for communication to server. Should be same as the option -shared-memory-base-name used for the mysqld server you want's to connect to. New in 4.1.0.

Note that the client group is always read if you use MySQL_READ_DEFAULT_FILE or MySQL_READ_DEFAULT_GROUP.

The specified group in the option file may contain the following options:

Option	Description
connect-timeout	Connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.
compress	Use the compressed client/server protocol.
database	Connect to this database if no database was specified in the connect command.
debug	Debug options.
disable-local-infile	Disable use of LOAD DATA LOCAL.
host	Default hostname.
init-command	Command to execute when connecting to MySQL server. Will automatically be re-executed when reconnecting.
interactive-timeout	Same as specifying CLIENT_INTERACTIVE to mysql_real_connect(). See Section 24.2.3.46, "mysql_real_connect()".
local-infile[=(0 1)]	If no argument or argument != 0 then enable use of LOAD DATA LOCAL.
max_allowed_packet	Max size of packet client can read from server.
multi-results	Allow multiple result sets from multiple-statement executions or stored procedures. New in 4.1.1.
multi-statements	Allow the client to send multiple statements in a single string (separated by ';'). New in 4.1.9.
password	Default password.
pipe	Use named pipes to connect to a MySQL server on NT.
protocol={TCP SOCKET PIPE	The protocol to use when connecting to server (New in 4.1)

MEMORY}	
port	Default port number.
return-found-rows	Tell <code>mysql_info()</code> to return found rows instead of updated rows when using UPDATE.
shared-memory-base-name= <i>me</i>	Shared memory name to use to connect to server (default is "MYSQL"). New in MySQL 4.1.
socket	Default socket file.
user	Default user.

Note that `timeout` has been replaced by `connect-timeout`, but `timeout` still works for a while.

For more information about option files, see Section 4.3.2, "Using Option Files".

Return Values

Zero for success. Non-zero if you used an unknown option.

Example

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql, MYSQL_OPT_COMPRESS, 0);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "odbc");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

This code requests the client to use the compressed client/server protocol and read the additional options from the `odbc` section in the `my.cnf` file.

24.2.3.44. `mysql_ping()`

```
int mysql_ping(MYSQL *mysql)
```

Description

Checks whether the connection to the server is working. If the connection has gone down, an automatic reconnection is attempted.

This function can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

Return Values

Zero if the connection to the server is alive. Non-zero if an error occurred. A non-zero return does not indicate whether the MySQL server itself is down; the connection might be broken for other reasons such as network problems.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.45. `mysql_query()`

```
int mysql_query(MYSQL *mysql, const char *query)
```

Description

Executes the SQL query pointed to by the null-terminated string `query`. Normally, the string must consist of a single SQL statement and you should not add a terminating semicolon (`;`) or `\g` to the statement. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See Section 24.2.9, “C API Handling of Multiple Query Execution”.

`mysql_query()` cannot be used for queries that contain binary data; you should use `mysql_real_query()` instead. (Binary data may contain the `\0` character, which `mysql_query()` interprets as the end of the query string.)

If you want to know whether the query should return a result set, you can use `mysql_field_count()` to check for this. See Section 24.2.3.20, “`mysql_field_count()`”.

Return Values

Zero if the query was successful. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.46. `mysql_real_connect()`

```
MYSQL *mysql_real_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd, const char *db, unsigned int port, const char *unix_socket, unsigned long client_flag)
```

Description

`mysql_real_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_real_connect()` must complete successfully before you can execute

any other API functions that require a valid MySQL connection handle structure.

The parameters are specified as follows:

- The first parameter should be the address of an existing MySQL structure. Before calling `mysql_real_connect()` you must call `mysql_init()` to initialize the MySQL structure. You can change a lot of connect options with the `mysql_options()` call. See Section 24.2.3.43, “`mysql_options()`”.
- The value of `host` may be either a hostname or an IP address. If `host` is `NULL` or the string “localhost”, a connection to the local host is assumed. If the OS supports sockets (Unix) or named pipes (Windows), they are used instead of TCP/IP to connect to the server.
- The `user` parameter contains the user's MySQL login ID. If `user` is `NULL` or the empty string “”, the current user is assumed. Under Unix, this is the current login name. Under Windows ODBC, the current username must be specified explicitly. See Section 25.1.9.2, “Configuring a MyODBC DSN on Windows”.
- The `passwd` parameter contains the password for `user`. If `passwd` is `NULL`, only entries in the `user` table for the user that have a blank (empty) password field are checked for a match. This allows the database administrator to set up the MySQL privilege system in such a way that users get different privileges depending on whether or not they have specified a password.

Note: Do not attempt to encrypt the password before calling `mysql_real_connect()`; password encryption is handled automatically by the client API.

- `db` is the database name. If `db` is not `NULL`, the connection sets the default database to this value.
- If `port` is not 0, the value is used as the port number for the TCP/IP connection. Note that the `host` parameter determines the type of the connection.
- If `unix_socket` is not `NULL`, the string specifies the socket or named pipe that should be used. Note that the `host` parameter determines the type of the connection.
- The value of `client_flag` is usually 0, but can be set to a combination of the following flags in very special circumstances:

Flag Name	Flag Description
<code>CLIENT_COMPRESS</code>	Use compression protocol.
<code>CLIENT_FOUND_ROWS</code>	Return the number of found (matched) rows, not the number of affected rows.
<code>CLIENT_IGNORE_SPACE</code>	Allow spaces after function names. Makes all functions names reserved words.
<code>CLIENT_INTERACTIVE</code>	Allow <code>interactive_timeout</code> seconds (instead of <code>wait_timeout</code> seconds) of inactivity before closing the connection. The client's session <code>wait_timeout</code> variable is set to the value of the session <code>interactive_timeout</code> variable.
<code>CLIENT_LOCAL_FILES</code>	Enable <code>LOAD DATA LOCAL</code> handling.
<code>CLIENT_MULTI_STATEMENTS</code>	Tell the server that the client may send multiple statements in a single string (separated by ';'). If this flag is not set, multiple-statement execution is disabled. New in 4.1.
<code>CLIENT_MULTI_RESULTS</code>	Tell the server that the client can handle multiple result sets from multiple-statement executions or stored procedures. This is automatically set if <code>CLIENT_MULTI_STATEMENTS</code> is set. New in 4.1.
<code>CLIENT_NO_SCHEMA</code>	Don't allow the <code>db_name.tbl_name.col_name</code> syntax. This is for ODBC. It causes the parser to generate an error if you use that syntax, which is useful for trapping bugs in some ODBC programs.

CLIENT_ODBC	The client is an ODBC client. This changes mysqld to be more ODBC-friendly.
CLIENT_SSL	Use SSL (encrypted protocol). This option should not be set by application programs; it is set internally in the client library.

Return Values

A `MYSQL*` connection handle if the connection was successful, `NULL` if the connection was unsuccessful. For a successful connection, the return value is the same as the value of the first parameter.

Errors

- `CR_CONN_HOST_ERROR`
Failed to connect to the MySQL server.
- `CR_CONNECTION_ERROR`
Failed to connect to the local MySQL server.
- `CR_IPSOCK_ERROR`
Failed to create an IP socket.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_SOCKET_CREATE_ERROR`
Failed to create a Unix socket.
- `CR_UNKNOWN_HOST`
Failed to find the IP address for the hostname.
- `CR_VERSION_ERROR`
A protocol mismatch resulted from attempting to connect to a server with a client library that uses a different protocol version. This can happen if you use a very old client library to connect to a new server that wasn't started with the `--old-protocol` option.
- `CR_NAMEDPIPEOPEN_ERROR`
Failed to create a named pipe on Windows.
- `CR_NAMEDPIPEWAIT_ERROR`
Failed to wait for a named pipe on Windows.
- `CR_NAMEDPIPESETSTATE_ERROR`
Failed to get a pipe handler on Windows.
- `CR_SERVER_LOST`
If `connect_timeout > 0` and it took longer than `connect_timeout` seconds to connect to the server or if the server died while executing the `init-command`.

Example

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql,MYSQL_READ_DEFAULT_GROUP,"your_prog_name");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr,"Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

By using `mysql_options()` the MySQL library reads the `[client]` and `[your_prog_name]` sections in the `my.cnf` file which ensures that your program works, even if someone has set up MySQL in some non-standard way.

Note that upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the MySQL structure) to a value of 1 in versions of the API strictly older than 5.0.3, of 0 in newer versions. A value of 1 for this flag indicates, in the event that a query cannot be performed because of a lost connection, to try reconnecting to the server before giving up.

24.2.3.47. `mysql_real_escape_string()`

```
unsigned long mysql_real_escape_string(MYSQL *mysql, char *to,
const char *from, unsigned long length)
```

Note that `mysql` must be a valid, open connection. This is needed because the escaping depends on the character-set in use by the server.

Description

This function is used to create a legal SQL string that you can use in a SQL statement. See Section 9.1.1, “Strings”.

The string in `from` is encoded to an escaped SQL string, taking into account the current character set of the connection. The result is placed in `to` and a terminating null byte is appended. Characters encoded are NUL (ASCII 0), `\n`, `\r`, `\`, `'`, `"`, and Control-Z (see Section 9.1, “Literal Values”). (Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. This function quotes the other characters to make them easier to read in log files.)

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. (In the worst case, each character may need to be encoded as using two bytes, and you need room for the terminating null byte.) When `mysql_real_escape_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null character.

Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
*end++ = '\\';
end += mysql_real_escape_string(&mysql, end,"What's this",11);
*end++ = '\\';
*end++ = ',';
*end++ = '\\';
end += mysql_real_escape_string(&mysql, end,"binary data: \\0\\r\\n",16);
*end++ = '\\';
*end++ = ')';

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr,"Failed to insert row, Error: %s\n",
```

```
        mysql_error(&mysql));  
}
```

The `strmov()` function used in the example is included in the `mysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

Return Values

The length of the value placed into `to`, not including the terminating null character.

Errors

None.

24.2.3.48. `mysql_real_query()`

```
int mysql_real_query(MYSQL *mysql, const char *query, unsigned long  
length)
```

Description

Executes the SQL query pointed to by `query`, which should be a string `length` bytes long. Normally, the string must consist of a single SQL statement and you should not add a terminating semicolon (;) or `\g` to the statement. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See Section 24.2.9, “C API Handling of Multiple Query Execution”.

You **must** use `mysql_real_query()` rather than `mysql_query()` for queries that contain binary data, because binary data may contain the `'\0'` character. In addition, `mysql_real_query()` is faster than `mysql_query()` because it does not call `strlen()` on the query string.

If you want to know whether the query should return a result set, you can use `mysql_field_count()` to check for this. See Section 24.2.3.20, “`mysql_field_count()`”.

Return Values

Zero if the query was successful. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.49. `mysql_reload()`

```
int mysql_reload(MYSQL *mysql)
```

Description

Asks the MySQL server to reload the grant tables. The connected user must have the RELOAD privilege.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL FLUSH PRIVILEGES statement instead.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC
Commands were executed in an improper order.
- CR_SERVER_GONE_ERROR
The MySQL server has gone away.
- CR_SERVER_LOST
The connection to the server was lost during the query.
- CR_UNKNOWN_ERROR
An unknown error occurred.

24.2.3.50. `mysql_row_seek()`

```
MYSQL_ROW_OFFSET mysql_row_seek(MYSQL_RES *result, MYSQL_ROW_OFFSET offset)
```

Description

Sets the row cursor to an arbitrary row in a query result set. The `offset` value is a row offset that should be a value returned from `mysql_row_tell()` or from `mysql_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_row_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_row_seek()`.

Errors

None.

24.2.3.51. `mysql_row_tell()`

```
MYSQL_ROW_OFFSET mysql_row_tell(MYSQL_RES *result)
```

Description

Returns the current position of the row cursor for the last `mysql_fetch_row()`. This value can

be used as an argument to `mysql_row_seek()`.

You should use `mysql_row_tell()` only after `mysql_store_result()`, not after `mysql_use_result()`.

Return Values

The current offset of the row cursor.

Errors

None.

24.2.3.52. `mysql_select_db()`

```
int mysql_select_db(MYSQL *mysql, const char *db)
```

Description

Causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that do not include an explicit database specifier.

`mysql_select_db()` fails unless the connected user can be authenticated as having permission to use the database.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.53. `mysql_set_server_option()`

```
int mysql_set_server_option(MYSQL *mysql, enum_mysql_set_option option)
```

Description

Enables or disables an option for the connection. `option` can have one of the following values:

<code>MYSQL_OPTION_MULTI_STATEMENTS_ON</code>	Enable multi statement support.
<code>MYSQL_OPTION_MULTI_STATEMENTS_OFF</code>	Disable multi statement support.

This function was added in MySQL 4.1.1.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `ER_UNKNOWN_COM_ERROR`
The server didn't support `mysql_set_server_option()` (which is the case that the server is older than 4.1.1) or the server didn't support the option one tried to set.

24.2.3.54. `mysql_shutdown()`

```
int mysql_shutdown(MYSQL *mysql, enum enum_shutdown_level shutdown_level)
```

Description

Asks the database server to shut down. The connected user must have SHUTDOWN privileges. The `shutdown_level` argument was added in MySQL 4.1.3 (and 5.0.1). The MySQL server currently supports only one type (level of gracefulness) of shutdown; `shutdown_level` must be equal to `SHUTDOWN_DEFAULT`. Later we will add more levels and then the `shutdown_level` argument will enable us to choose the desired level. MySQL servers and MySQL clients before and after 4.1.3 are compatible; MySQL servers newer than 4.1.3 accept the `mysql_shutdown(MYSQL *mysql)` call, and MySQL servers older than 4.1.3 accept the new `mysql_shutdown()` call. But dynamically linked executables which have been compiled with older versions of `libmysqlclient` headers, and call `mysql_shutdown()`, need to be used with the old `libmysqlclient` dynamic library.

The shutdown process is described in Section 5.4, “The MySQL Server Shutdown Process”.

Return Values

Zero for success. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

24.2.3.55. `mysql_sqlstate()`

```
const char *mysql_sqlstate(MYSQL *mysql)
```

Description

Returns a null-terminated string containing the `SQLSTATE` error code for the last error. The error code consists of five characters. '00000' means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see Chapter 26, *Error Handling in MySQL*.

Note that not all MySQL errors are yet mapped to `SQLSTATE`'s. The value 'HY000' (general error) is used for unmapped errors.

This function was added to MySQL 4.1.1.

Return Values

A null-terminated character string containing the `SQLSTATE` error code.

See Also

See Section 24.2.3.12, "`mysql_errno()`". See Section 24.2.3.13, "`mysql_error()`". See Section 24.2.7.26, "`mysql_stmt_sqlstate()`".

24.2.3.56. `mysql_ssl_set()`

```
int mysql_ssl_set(MYSQL *mysql, const char *key, const char *cert,
const char *ca, const char *capath, const char *cipher)
```

Description

`mysql_ssl_set()` is used for establishing secure connections using SSL. It must be called before `mysql_real_connect()`.

`mysql_ssl_set()` does nothing unless OpenSSL support is enabled in the client library.

`mysql` is the connection handler returned from `mysql_init()`. The other parameters are specified as follows:

- `key` is the pathname to the key file.
- `cert` is the pathname to the certificate file.
- `ca` is the pathname to the certificate authority file.
- `capath` is the pathname to a directory that contains trusted SSL CA certificates in pem format.
- `cipher` is a list of allowable ciphers to use for SSL encryption.

Any unused SSL parameters may be given as `NULL`.

Return Values

This function always returns 0. If SSL setup is incorrect, `mysql_real_connect()` returns an

error when you attempt to connect.

24.2.3.57. `mysql_stat()`

```
char *mysql_stat(MYSQL *mysql)
```

Description

Returns a character string containing information similar to that provided by the `mysqladmin status` command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

Return Values

A character string describing the server status. NULL if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.58. `mysql_store_result()`

```
MYSQL_RES *mysql_store_result(MYSQL *mysql)
```

Description

You must call `mysql_store_result()` or `mysql_use_result()` for every query that successfully retrieves data (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth).

You don't have to call `mysql_store_result()` or `mysql_use_result()` for other queries, but it does not do any harm or cause any notable performance degradation if you call `mysql_store_result()` in all cases. You can detect if the query didn't have a result set by checking if `mysql_store_result()` returns 0 (more about this later on).

If you want to know whether the query should return a result set, you can use `mysql_field_count()` to check for this. See Section 24.2.3.20, “`mysql_field_count()`”.

`mysql_store_result()` reads the entire result of a query to the client, allocates a `MYSQL_RES` structure, and places the result into this structure.

`mysql_store_result()` returns a null pointer if the query didn't return a result set (if the query was, for example, an `INSERT` statement).

`mysql_store_result()` also returns a null pointer if reading of the result set failed. You can check whether an error occurred by checking if `mysql_error()` returns a non-empty string, if `mysql_errno()` returns non-zero, or if `mysql_field_count()` returns zero.

An empty result set is returned if there are no rows returned. (An empty result set differs from a null pointer as a return value.)

Once you have called `mysql_store_result()` and got a result back that isn't a null pointer, you may call `mysql_num_rows()` to find out how many rows are in the result set.

You can call `mysql_fetch_row()` to fetch rows from the result set, or `mysql_row_seek()` and `mysql_row_tell()` to obtain or set the current row position within the result set.

You must call `mysql_free_result()` once you are done with the result set.

See Section 24.2.13.1, “Why `mysql_store_result()` Sometimes Returns `NULL` After `mysql_query()` Returns Success”.

Return Values

A `MYSQL_RES` result structure with the results. `NULL` if an error occurred.

Errors

`mysql_store_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.59. `mysql_thread_id()`

```
unsigned long mysql_thread_id(MYSQL *mysql)
```

Description

Returns the thread ID of the current connection. This value can be used as an argument to `mysql_kill()` to kill the thread.

If the connection is lost and you reconnect with `mysql_ping()`, the thread ID changes. This means you should not get the thread ID and store it for later. You should get it when you need it.

Return Values

The thread ID of the current connection.

Errors

None.

24.2.3.60. `mysql_use_result()`

```
MYSQL_RES *mysql_use_result(MYSQL *mysql)
```

Description

You must call `mysql_store_result()` or `mysql_use_result()` for every query that successfully retrieves data (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`).

`mysql_use_result()` initiates a result set retrieval but does not actually read the result set into the client like `mysql_store_result()` does. Instead, each row must be retrieved individually by making calls to `mysql_fetch_row()`. This reads the result of a query directly from the server without storing it in a temporary table or local buffer, which is somewhat faster and uses much less memory than `mysql_store_result()`. The client allocates memory only for the current row and a communication buffer that may grow up to `max_allowed_packet` bytes.

On the other hand, you shouldn't use `mysql_use_result()` if you are doing a lot of processing for each row on the client side, or if the output is sent to a screen on which the user may type a ^S (stop scroll). This ties up the server and prevent other threads from updating any tables from which the data is being fetched.

When using `mysql_use_result()`, you must execute `mysql_fetch_row()` until a `NULL` value is returned, otherwise, the unfetched rows are returned as part of the result set for your next query. The C API gives the error `Commands out of sync; you can't run this command now` if you forget to do this!

You may not use `mysql_data_seek()`, `mysql_row_seek()`, `mysql_row_tell()`, `mysql_num_rows()`, or `mysql_affected_rows()` with a result returned from `mysql_use_result()`, nor may you issue other queries until the `mysql_use_result()` has finished. (However, after you have fetched all the rows, `mysql_num_rows()` accurately returns the number of rows fetched.)

You must call `mysql_free_result()` once you are done with the result set.

Return Values

A `MYSQL_RES` result structure. `NULL` if an error occurred.

Errors

`mysql_use_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.3.61. mysql_warning_count ()

```
unsigned int mysql_warning_count(MYSQL *mysql)
```

Description

Returns the number of warnings generated during execution of the previous SQL statement.

This function was added in MySQL 4.1.0.

Return Values

The warning count.

Errors

None.

24.2.3.62. mysql_commit ()

```
my_bool mysql_commit(MYSQL *mysql)
```

Description

Commits the current transaction.

This function was added in MySQL 4.1.0.

Return Values

Zero if successful. Non-zero if an error occurred.

Errors

None.

24.2.3.63. mysql_rollback ()

```
my_bool mysql_rollback(MYSQL *mysql)
```

Description

Rolls back the current transaction.

This function was added in MySQL 4.1.0.

Return Values

Zero if successful. Non-zero if an error occurred.

Errors

None.

24.2.3.64. mysql_autocommit ()

```
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

Description

Sets autocommit mode on if mode is 1, off if mode is 0.

This function was added in MySQL 4.1.0.

Return Values

Zero if successful. Non-zero if an error occurred.

Errors

None.

24.2.3.65. `mysql_more_results()`

```
my_bool mysql_more_results(MYSQL *mysql)
```

Description

Returns true if more results exist from the currently executed query, and the application must call `mysql_next_result()` to fetch the results.

This function was added in MySQL 4.1.0.

Return Values

TRUE (1) if more results exist. FALSE (0) if no more results exist.

In most cases, you can call `mysql_next_result()` instead to test whether more results exist and initiate retrieval if so.

See Section 24.2.9, “C API Handling of Multiple Query Execution”. See Section 24.2.3.66, “`mysql_next_result()`”.

Errors

None.

24.2.3.66. `mysql_next_result()`

```
int mysql_next_result(MYSQL *mysql)
```

Description

If more query results exist, `mysql_next_result()` reads the next query results and returns the status back to application.

You must call `mysql_free_result()` for the preceding query if it returned a result set.

After calling `mysql_next_result()` the state of the connection is as if you had called `mysql_real_query()` or `mysql_query()` for the next query. This means that you can call `mysql_store_result()`, `mysql_warning_count()`, `mysql_affected_rows()`, and so forth.

If `mysql_next_result()` returns an error, no other statements are executed and there are no more results to fetch.

See Section 24.2.9, “C API Handling of Multiple Query Execution”.

This function was added in MySQL 4.1.0.

Return Values

Return Value	Description
0	Successful and there are more results
#1	Successful and there are no more results
>0	An error occurred

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order. For example if you didn't call `mysql_use_result()` for a previous result set.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

24.2.4. C API Prepared Statements

As of MySQL 4.1, the client/server protocol provides for the use of prepared statements. This capability uses the `MYSQL_STMT` statement handler data structure returned by the `mysql_stmt_init()` initialization function. Prepared execution is an efficient way to execute a statement more than once. The statement is first parsed to prepare it for execution. Then it is executed one or more times at a later time, using the statement handle returned by the initialization function.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

The following statements can be used as prepared statements: `CREATE TABLE`, `DELETE`, `DO`, `INSERT`, `REPLACE`, `SELECT`, `SET`, `UPDATE`, and most `SHOW` statements. Other statements are not yet supported.

24.2.5. C API Prepared Statement Data types

Note: Some incompatible changes were made in MySQL 4.1.2. See Section 24.2.7, “C API Prepared Statement Function Descriptions” for details.

Prepared statements mainly use the `MYSQL_STMT` and `MYSQL_BIND` data structures. A third structure, `MYSQL_TIME`, is used to transfer temporal data.

- `MYSQL_STMT`

This structure represents a prepared statement. A statement is created by calling `mysql_stmt_init()`, which returns a statement handle, that is, a pointer to a `MYSQL_STMT`. The handle is used for all subsequent statement-related functions until you close it with `mysql_stmt_close()`.

The `MYSQL_STMT` structure has no members that are for application use.

Multiple statement handles can be associated with a single connection. The limit on the number of handles depends on the available system resources.

- `MYSQL_BIND`

This structure is used both for statement input (data values sent to the server) and output (result values returned from the server). For input, it is used with `mysql_stmt_bind_param()` to bind parameter data values to buffers for use by `mysql_stmt_execute()`. For output, it is used with `mysql_stmt_bind_result()` to bind result set buffers for use in fetching rows with `mysql_stmt_fetch()`.

The `MYSQL_BIND` structure contains the following members for use by application programs. Each is used both for input and for output, although sometimes for different purposes depending on the direction of data transfer.

- `enum enum_field_types buffer_type`

The type of the buffer. The allowable `buffer_type` values are listed later in this section. For input, `buffer_type` indicates what type of value you are binding to a statement parameter. For output, it indicates what type of value you expect to receive in a result buffer.

- `void *buffer`

For input, this is a pointer to the buffer in which a statement parameter's data value is stored. For output, it is a pointer to the buffer in which to return a result set column value. For numeric column types, `buffer` should point to a variable of the proper C type. (If you are associating the variable with a column that has the `UNSIGNED` attribute, the variable should be an `unsigned` C type. Indicate whether the variable is signed or unsigned by using the `is_unsigned` member, described later in this list.) For date and time column types, `buffer` should point to a `MYSQL_TIME` structure. For character and binary string column types, `buffer` should point to a character buffer.

- `unsigned long buffer_length`

The actual size of `*buffer` in bytes. This indicates the maximum amount of data that can be stored in the buffer. For character and binary C data, the `buffer_length` value specifies the length of `*buffer` when used with `mysql_stmt_bind_param()`, or the maximum number of data bytes that can be fetched into the buffer when used with `mysql_stmt_bind_result()`.

- `unsigned long *length`

A pointer to an `unsigned long` variable that indicates the actual number of bytes of data stored in `*buffer`. `length` is used for character or binary C data. For input parameter data binding, `length` points to an `unsigned long` variable that indicates the length of the parameter value stored in `*buffer`; this is used by `mysql_stmt_execute()`. For output value binding, `mysql_stmt_fetch()` places the length of the column value that is returned into the variable that `length` points to.

`length` is ignored for numeric and temporal data types because the length of the data value is determined by the `buffer_type` value.

- `my_bool *is_null`

This member points to a `my_bool` variable that is true if a value is `NULL`, false if it is not `NULL`. For input, set `*is_null` to true to indicate that you are passing a `NULL` value as a statement parameter. For output, this value is set to true after you fetch a row if the result set column value returned from the statement is `NULL`.

- `my_bool is_unsigned`

This member is used for integer types. (These correspond to the `MYSQL_TYPE_TINY`, `MYSQL_TYPE_SHORT`, `MYSQL_TYPE_LONG`, and `MYSQL_TYPE_LONGLONG` type codes.) `is_unsigned` should be set to true for unsigned types and false for signed types.

- `my_bool error`

For output, this member is used output to report data truncation errors. Truncation reporting must be enabled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option. When enabled, `mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED` and `error` is true in the `MYSQL_BIND` structures for parameters in which truncation occurred. Truncation indicates loss of sign or significant digits, or that a string was too long to fit in a column. The `error` member was added in MySQL 5.0.3.

To use a `MYSQL_BIND` structure, you should zero its contents to initialize it, and then set the members just described appropriately. For example, to declare and initialize an array of three `MYSQL_BIND` structures, use this code:

```
MYSQL_BIND    bind[3];
memset(bind, 0, sizeof(bind));
```

- `MYSQL_TIME`

This structure is used to send and receive `DATE`, `TIME`, `DATETIME`, and `TIMESTAMP` data directly to and from the server. This is done by setting the `buffer_type` member of a `MYSQL_BIND` structure to one of the temporal types, and setting the `buffer` member to point to a `MYSQL_TIME` structure.

The `MYSQL_TIME` structure contains the following members:

- `unsigned int year`

The year.

- `unsigned int month`

The month of the year.

- `unsigned int day`

The day of the month.

- `unsigned int hour`

The hour of the day.

- `unsigned int minute`

The minute of the hour.

- `unsigned int second`

The second of the minute.

- `my_bool neg`

A boolean flag to indicate whether the time is negative.

- `unsigned long second_part`

The fractional part of the second. This member currently is unused.

Only those parts of a `MYSQL_TIME` structure that apply to a given type of temporal value are used: The year, month, and day elements are used for `DATE`, `DATETIME`, and `TIMESTAMP` values. The hour, minute, and second elements are used for `TIME`, `DATETIME`, and `TIMESTAMP` values. See Section 24.2.10, “C API Handling of Date and Time Values”.

The following table shows the allowable values that may be specified in the `buffer_type` member of `MYSQL_BIND` structures. The table also shows those SQL types that correspond most closely to each `buffer_type` value, and, for numeric and temporal types, the corresponding C type.

<code>buffer_type</code> Value	SQL Type	C Type
<code>MYSQL_TYPE_TINY</code>	<code>TINYINT</code>	<code>char</code>
<code>MYSQL_TYPE_SHORT</code>	<code>SMALLINT</code>	<code>short int</code>
<code>MYSQL_TYPE_LONG</code>	<code>INT</code>	<code>int</code>
<code>MYSQL_TYPE_LONGLONG</code>	<code>BIGINT</code>	<code>long long int</code>
<code>MYSQL_TYPE_FLOAT</code>	<code>FLOAT</code>	<code>float</code>
<code>MYSQL_TYPE_DOUBLE</code>	<code>DOUBLE</code>	<code>double</code>
<code>MYSQL_TYPE_TIME</code>	<code>TIME</code>	<code>MYSQL_TIME</code>
<code>MYSQL_TYPE_DATE</code>	<code>DATE</code>	<code>MYSQL_TIME</code>
<code>MYSQL_TYPE_DATETIME</code>	<code>DATETIME</code>	<code>MYSQL_TIME</code>
<code>MYSQL_TYPE_TIMESTAMP</code>	<code>TIMESTAMP</code>	<code>MYSQL_TIME</code>
<code>MYSQL_TYPE_STRING</code>	<code>CHAR</code>	
<code>MYSQL_TYPE_VAR_STRING</code>	<code>VARCHAR</code>	
<code>MYSQL_TYPE_TINY_BLOB</code>	<code>TINYBLOB/TINYTEXT</code>	
<code>MYSQL_TYPE_BLOB</code>	<code>BLOB/TEXT</code>	
<code>MYSQL_TYPE_MEDIUM_BLOB</code>	<code>MEDIUMBLOB/MEDIUMTEXT</code>	
<code>MYSQL_TYPE_LONG_BLOB</code>	<code>LOB/LONGTEXT</code>	

Implicit type conversion may be performed in both directions.

24.2.6. C API Prepared Statement Function Overview

Note: Some incompatible changes were made in MySQL 4.1.2. See Section 24.2.7, “C API Prepared Statement Function Descriptions” for details.

The functions available for prepared statement processing are summarized here and described in greater detail in a later section. See Section 24.2.7, “C API Prepared Statement Function Descriptions”.

Function	Description
<code>mysql_stmt_affected_rows()</code>	Returns the number of rows changes, deleted, or inserted by prepared <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> statement.
<code>mysql_stmt_attr_get()</code>	Get value of an attribute for a prepared statement.
<code>mysql_stmt_attr_set()</code>	Sets an attribute for a prepared statement.
<code>mysql_stmt_bind_param()</code>	Associates application data buffers with the parameter markers in a prepared SQL statement.
<code>mysql_stmt_bind_result()</code>	Associates application data buffers with columns in the result set.
<code>mysql_stmt_close()</code>	Frees memory used by prepared statement.

mysql_stmt_data_seek()	Seeks to an arbitrary row number in a statement result set.
mysql_stmt_errno()	Returns the error number for the last statement execution.
mysql_stmt_error()	Returns the error message for the last statement execution.
mysql_stmt_execute()	Executes the prepared statement.
mysql_stmt_fetch()	Fetches the next row of data from the result set and returns data for all bound columns.
mysql_stmt_fetch_column()	Fetch data for one column of the current row of the result set.
mysql_stmt_field_count()	Returns the number of result columns for the most recent statement.
mysql_stmt_free_result()	Free the resources allocated to the statement handle.
mysql_stmt_init()	Allocates memory for MYSQL_STMT structure and initializes it.
mysql_stmt_insert_id()	Returns the ID generated for an AUTO_INCREMENT column by prepared statement.
mysql_stmt_num_rows()	Returns total rows from the statement buffered result set.
mysql_stmt_param_count()	Returns the number of parameters in a prepared SQL statement.
mysql_stmt_param_metadata()	Return parameter metadata in the form of a result set.
mysql_stmt_prepare()	Prepares an SQL string for execution.
mysql_stmt_reset()	Reset the statement buffers in the server.
mysql_stmt_result_metadata()	Returns prepared statement metadata in the form of a result set.
mysql_stmt_row_seek()	Seeks to a row offset in a statement result set, using value returned from <code>mysql_stmt_row_tell()</code> .
mysql_stmt_row_tell()	Returns the statement row cursor position.
mysql_stmt_send_long_data()	Sends long data in chunks to server.
mysql_stmt_sqlstate()	Returns the SQLSTATE error code for the last statement execution.
mysql_stmt_store_result()	Retrieves the complete result set to the client.

Call `mysql_stmt_init()` to create a statement handle, then `mysql_stmt_prepare()` to prepare it, `mysql_stmt_bind_param()` to supply the parameter data, and `mysql_stmt_execute()` to execute the statement. You can repeat the `mysql_stmt_execute()` by changing parameter values in the respective buffers supplied through `mysql_stmt_bind_param()`.

If the statement is a `SELECT` or any other statement that produces a result set, `mysql_stmt_prepare()` also returns the result set metadata information in the form of a `MYSQL_RES` result set through `mysql_stmt_result_metadata()`.

You can supply the result buffers using `mysql_stmt_bind_result()`, so that the `mysql_stmt_fetch()` automatically returns data to these buffers. This is row-by-row fetching.

You can also send the text or binary data in chunks to server using `mysql_stmt_send_long_data()`. See Section 24.2.7.25, “`mysql_stmt_send_long_data()`”.

When statement execution has been completed, the statement handle must be closed using `mysql_stmt_close()` so that all resources associated with it can be freed.

If you obtained a `SELECT` statement's result set metadata by calling `mysql_stmt_result_metadata()`, you should also free the metadata using `mysql_free_result()`.

Execution Steps

To prepare and execute a statement, an application follows these steps:

1. Create a prepared statement handle with `mysql_stmt_init()`. To prepare the statement on the server, call `mysql_stmt_prepare()` and pass it a string containing the SQL statement.
2. If the statement produces a result set, call `mysql_stmt_result_metadata()` to obtain the result set metadata. This metadata is itself in the form of result set, albeit a separate one from the one that contains the rows returned by the query. The metadata result set indicates how many columns are in the result and contains information about each column.
3. Set the values of any parameters using `mysql_stmt_bind_param()`. All parameters must be set. Otherwise, statement execution returns an error or produces unexpected results.
4. Call `mysql_stmt_execute()` to execute the statement.
5. If the statement produces a result set, bind the data buffers to use for retrieving the row values by calling `mysql_stmt_bind_result()`.
6. Fetch the data into the buffers row by row by calling `mysql_stmt_fetch()` repeatedly until no more rows are found.
7. Repeat steps 3 through 6 as necessary, by changing the parameter values and re-executing the statement.

When `mysql_stmt_prepare()` is called, the MySQL client/server protocol performs these actions:

- The server parses the statement and sends the okay status back to the client by assigning a statement ID. It also sends total number of parameters, a column count, and its metadata if it is a result set oriented statement. All syntax and semantics of the statement are checked by the server during this call.
- The client uses this statement ID for the further operations, so that the server can identify the statement from among its pool of statements.

When `mysql_stmt_execute()` is called, the MySQL client/server protocol performs these actions:

- The client uses the statement handle and sends the parameter data to the server.
- The server identifies the statement using the ID provided by the client, replaces the parameter markers with the newly supplied data, and executes the statement. If the statement produces a result set, the server sends the data back to the client. Otherwise, it sends an okay status and total number of rows changed, deleted, or inserted.

When `mysql_stmt_fetch()` is called, the MySQL client/server protocol performs these actions:

- The client reads the data from the packet row by row and places it into the application data buffers by doing the necessary conversions. If the application buffer type is same as that of the field type returned from the server, the conversions are straightforward.

If an error occurs, you can get the statement error code, error message, and `SQLSTATE` value using `mysql_stmt_errno()`, `mysql_stmt_error()`, and `mysql_stmt_sqlstate()`, re-

spectively.

24.2.7. C API Prepared Statement Function Descriptions

To prepare and execute queries, use the functions in the following sections.

In MySQL 4.1.2, the names of several prepared statement functions were changed:

Old Name	New Name
<code>mysql_bind_param()</code>	<code>mysql_stmt_bind_param()</code>
<code>mysql_bind_result()</code>	<code>mysql_stmt_bind_result()</code>
<code>mysql_prepare()</code>	<code>mysql_stmt_prepare()</code>
<code>mysql_execute()</code>	<code>mysql_stmt_execute()</code>
<code>mysql_fetch()</code>	<code>mysql_stmt_fetch()</code>
<code>mysql_fetch_column()</code>	<code>mysql_stmt_fetch_column()</code>
<code>mysql_param_count()</code>	<code>mysql_stmt_param_count()</code>
<code>mysql_param_result()</code>	<code>mysql_stmt_param_metadata()</code>
<code>mysql_get_metadata()</code>	<code>mysql_stmt_result_metadata()</code>
<code>mysql_send_long_data()</code>	<code>mysql_stmt_send_long_data()</code>

All functions that operate with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

Also in 4.1.2, the signature of the `mysql_stmt_prepare()` function was changed to `int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *query, unsigned long length)`. To create a `MYSQL_STMT` handle, you should use the `mysql_stmt_init()` function.

24.2.7.1. `mysql_stmt_affected_rows()`

```
my_ulonglong mysql_stmt_affected_rows(MYSQL_STMT *stmt)
```

Description

Returns the total number of rows changed, deleted, or inserted by the last executed statement. May be called immediately after `mysql_stmt_execute()` for `UPDATE`, `DELETE`, or `INSERT` statements. For `SELECT` statements, `mysql_stmt_affected_rows()` works like `mysql_num_rows()`.

This function was added in MySQL 4.1.0.

Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query, or that no query has yet been executed. `#1` indicates that the query returned an error or that, for a `SELECT` query, `mysql_stmt_affected_rows()` was called prior to calling `mysql_stmt_store_result()`. Because `mysql_stmt_affected_rows()` returns an unsigned value, you can check for `#1` by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

See Section 24.2.3.1, “`mysql_affected_rows()`” for additional information on the return value.

Errors

None.

Example

For the usage of `mysql_stmt_affected_rows()`, refer to the Example from Section 24.2.7.10, “`mysql_stmt_execute()`”.

24.2.7.2. `mysql_stmt_attr_get()`

```
int mysql_stmt_attr_get(MYSQL_STMT *stmt, enum enum_stmt_attr_type
option, void *arg)
```

Description

Can be used to get the current value for a statement attribute.

The `option` argument is the option that you want to get; the `arg` should point to a variable that should contain the option value. If the option is an integer, then `arg` should point to the value of the integer.

See `mysql_stmt_attr_set()` for a list of options and option types. See Section 24.2.7.3, “`mysql_stmt_attr_set()`”.

This function was added in MySQL 4.1.2.

Return Values

0 if okay. Non-zero if `option` is unknown.

Errors

None.

24.2.7.3. `mysql_stmt_attr_set()`

```
int mysql_stmt_attr_set(MYSQL_STMT *stmt, enum enum_stmt_attr_type
option, const void *arg)
```

Description

Can be used to set affect behavior for a statement. This function may be called multiple times to set several options.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, then `arg` should point to the value of the integer.

Possible option values:

Option	Argument Type	Function
STMT_ATTR_UPDATE_MAX_LENGTH	my_bool *	If set to 1: Update metadata MySQL_FIELD->max_length in <code>mysql_stmt_store_result()</code> .

This function was added in MySQL 4.1.2.

Return Values

0 if okay. Non-zero if `option` is unknown.

Errors

None.

24.2.7.4. `mysql_stmt_bind_param()`

```
my_bool mysql_stmt_bind_param(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

Description

`mysql_stmt_bind_param()` is used to bind data for the parameter markers in the SQL statement that was passed to `mysql_stmt_prepare()`. It uses `MYSQL_BIND` structures to supply the data. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain an element for each '?' parameter marker that is present in the query.

Suppose that you prepare the following statement:

```
INSERT INTO mytbl VALUES(?, ?, ?)
```

When you bind the parameters, the array of `MYSQL_BIND` structures must contain three elements, and can be declared like this:

```
MYSQL_BIND bind[3];
```

The members of each `MYSQL_BIND` element that should be set are described in Section 24.2.5, “C API Prepared Statement Data types”.

This function was added in MySQL 4.1.2.

Return Values

Zero if the bind was successful. Non-zero if an error occurred.

Errors

- `CR_INVALID_BUFFER_USE`

Indicates if the bind is to supply the long data in chunks and if the buffer type is non string or binary.

- `CR_UNSUPPORTED_PARAM_TYPE`

The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

Example

For the usage of `mysql_stmt_bind_param()`, refer to the Example from Section 24.2.7.10, “`mysql_stmt_execute()`”.

24.2.7.5. `mysql_stmt_bind_result()`

```
my_bool mysql_stmt_bind_result(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

Description

`mysql_stmt_bind_result()` is used to associate (bind) columns in the result set to data buffers and length buffers. When `mysql_stmt_fetch()` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified buffers.

All columns must be bound to buffers prior to calling `mysql_stmt_fetch()`. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain an element for each column of the result set. If you do not bind columns to `MYSQL_BIND` structures, `mysql_stmt_fetch()` simply ignores the data fetch. The buffers should be large enough to hold the data values, because the protocol doesn't return data values in chunks.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysql_stmt_fetch()` is called. Suppose that an application binds the columns in a result set and calls `mysql_stmt_fetch()`. The client/server protocol returns data in the bound buffers. Then suppose that the application binds the columns to a different set of buffers. The protocol does not place data into the newly bound buffers until the next call to `mysql_stmt_fetch()` occurs.

To bind a column, an application calls `mysql_stmt_bind_result()` and passes the type, address, and the address of the length buffer. The members of each `MYSQL_BIND` element that should be set are described in Section 24.2.5, "C API Prepared Statement Data types".

This function was added in MySQL 4.1.2.

Return Values

Zero if the bind was successful. Non-zero if an error occurred.

Errors

- `CR_UNSUPPORTED_PARAM_TYPE`

The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

Example

For the usage of `mysql_stmt_bind_result()`, refer to the Example from Section 24.2.7.13, "`mysql_stmt_fetch()`".

24.2.7.6. `mysql_stmt_close()`

```
my_bool mysql_stmt_close(MYSQL_STMT *)
```

Description

Closes the prepared statement. `mysql_stmt_close()` also deallocates the statement handle pointed to by `stmt`.

If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

This function was added in MySQL 4.1.0.

Return Values

Zero if the statement was freed successfully. Non-zero if an error occurred.

Errors

- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

Example

For the usage of `mysql_stmt_close()`, refer to the Example from Section 24.2.7.10, “`mysql_stmt_execute()`”.

24.2.7.7. `mysql_stmt_data_seek()`

```
void mysql_stmt_data_seek(MYSQL_STMT *stmt, my_ulonglong offset)
```

Description

Seeks to an arbitrary row in a statement result set. The `offset` value is a row number and should be in the range from 0 to `mysql_stmt_num_rows(stmt)-1`.

This function requires that the statement result set structure contains the entire result of the last executed query, so `mysql_stmt_data_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

This function was added in MySQL 4.1.1.

Return Values

None.

Errors

None.

24.2.7.8. `mysql_stmt_errno()`

```
unsigned int mysql_stmt_errno(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_errno()` returns the error code for the most recently invoked statement API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. In the MySQL source distribution you can find a complete list of error messages and error numbers in the file `Docs/mysqld_error.txt`. The server error codes also are listed at Chapter 26, *Error Handling in MySQL*.

This function was added in MySQL 4.1.0.

Return Values

An error code value. Zero if no error occurred.

Errors

None.

24.2.7.9. `mysql_stmt_error()`

```
const char *mysql_stmt_error(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_error()` returns a null-terminated string containing the error message for the most recently invoked statement API function that can succeed or fail. An empty string (" ") is returned if no error occurred. This means the following two tests are equivalent:

```
if (mysql_stmt_errno(stmt))
{
    // an error occurred
}

if (mysql_stmt_error(stmt)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. Currently you can choose error messages in several different languages.

This function was added in MySQL 4.1.0.

Return Values

A character string that describes the error. An empty string if no error occurred.

Errors

None.

24.2.7.10. `mysql_stmt_execute()`

```
int mysql_stmt_execute(MYSQL_STMT *stmt)
```

Description

`mysql_stmt_execute()` executes the prepared query associated with the statement handle. The currently bound parameter marker values are sent to server during this call, and the server replaces the markers with this newly supplied data.

If the statement is an UPDATE, DELETE, or INSERT, the total number of changed, deleted, or inserted rows can be found by calling `mysql_stmt_affected_rows()`. If this is a result set query such as SELECT, you must call `mysql_stmt_fetch()` to fetch the data prior to calling any other functions that result in query processing. For more information on how to fetch the results, refer to Section 24.2.7.13, “`mysql_stmt_fetch()`”.

This function was added in MySQL 4.1.2.

Return Values

Zero if execution was successful. Non-zero if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC
Commands were executed in an improper order.
- CR_OUT_OF_MEMORY
Out of memory.
- CR_SERVER_GONE_ERROR
The MySQL server has gone away.
- CR_SERVER_LOST
The connection to the server was lost during the query.
- CR_UNKNOWN_ERROR
An unknown error occurred.

Example

The following example demonstrates how to create and populate a table using `mysql_stmt_init()`, `mysql_stmt_prepare()`, `mysql_stmt_param_count()`, `mysql_stmt_bind_param()`, `mysql_stmt_execute()`, and `mysql_stmt_affected_rows()`. The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define DROP_SAMPLE_TABLE "DROP TABLE IF EXISTS test_table"
#define CREATE_SAMPLE_TABLE "CREATE TABLE test_table(coll INT,\
                                                    col2 VARCHAR(40),\
                                                    col3 SMALLINT,\
                                                    col4 TIMESTAMP)"

#define INSERT_SAMPLE "INSERT INTO test_table(coll,col2,col3) VALUES(?,?,?)"

MYSQL_STMT      *stmt;
MYSQL_BIND      bind[3];
my_ulonglong    affected_rows;
int             param_count;
short          small_data;
int            int_data;
char           str_data[STRING_SIZE];
unsigned long   str_length;
my_bool        is_null;

if (mysql_query(mysql, DROP_SAMPLE_TABLE))
{
    fprintf(stderr, " DROP TABLE failed\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

if (mysql_query(mysql, CREATE_SAMPLE_TABLE))
{
    fprintf(stderr, " CREATE TABLE failed\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

/* Prepare an INSERT query with 3 parameters */
/* (the TIMESTAMP column is not named; the server */
```

```
/* sets it to the current date and time) */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{

small_data= 1000; /* smallint */
is_null= 0; /* reset */

/* Execute the INSERT statement - 2*/
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute, 2 failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get the total rows affected */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 2): %lu\n",
        (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");
    exit(0);
}

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
```

Note: For complete examples on the use of prepared statement functions, refer to the file `tests/mysql_client_test.c`. This file can be obtained from a MySQL source distribution or from the BitKeeper source repository.

24.2.7.11. `mysql_stmt_free_result()`

```
my_bool mysql_stmt_free_result(MYSQL_STMT *stmt)
```

Description

Releases memory associated with the result set produced by execution of the prepared statement.

This function was added in MySQL 4.1.1.

Return Values

Zero if the result set was freed successfully. Non-zero if an error occurred.

Errors**24.2.7.12. `mysql_stmt_insert_id()`**

```
my_ulonglong mysql_stmt_insert_id(MYSQL_STMT *stmt)
```

Description

Returns the value generated for an `AUTO_INCREMENT` column by the prepared `INSERT` or `UPDATE` statement. Use this function after you have executed prepared `INSERT` statement into a table which contains an `AUTO_INCREMENT` field.

See Section 24.2.3.33, “`mysql_insert_id()`” for more information.

This function was added in MySQL 4.1.2.

Return Values

Value for `AUTO_INCREMENT` column which was automatically generated or explicitly set during execution of prepared statement, or value generated by `LAST_INSERT_ID(expr)` function. Return value is undefined if statement does not set `AUTO_INCREMENT` value.

Errors

None.

24.2.7.13. `mysql_stmt_fetch()`

```
int mysql_stmt_fetch(MYSQL_STMT *stmt)
```

Description

`mysql_stmt_fetch()` returns the next row in the result set. It can be called only while the result set exists, that is, after a call to `mysql_stmt_execute()` that creates a result set or after `mysql_stmt_store_result()`, which is called after `mysql_stmt_execute()` to buffer the entire result set.

`mysql_stmt_fetch()` returns row data using the buffers bound by `mysql_stmt_bind_result()`. It returns the data in those buffers for all the columns in the current row set and the lengths are returned to the `length` pointer.

All columns must be bound by the application before calling `mysql_stmt_fetch()`.

If a fetched data value is a `NULL` value, the `*is_null` value of the corresponding `MYSQL_BIND` structure contains `TRUE` (1). Otherwise, the data and its length are returned in the `*buffer` and `*length` elements based on the buffer type specified by the application. Each numeric and temporal type has a fixed length, as listed in the following table. The length of the string types depends on the length of the actual data value, as indicated by `data_length`.

Type	Length
<code>MYSQL_TYPE_TINY</code>	1
<code>MYSQL_TYPE_SHORT</code>	2
<code>MYSQL_TYPE_LONG</code>	4
<code>MYSQL_TYPE_LONGLONG</code>	8
<code>MYSQL_TYPE_FLOAT</code>	4
<code>MYSQL_TYPE_DOUBLE</code>	8
<code>MYSQL_TYPE_TIME</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_DATE</code>	<code>sizeof(MYSQL_TIME)</code>
<code>MYSQL_TYPE_DATETIME</code>	<code>sizeof(MYSQL_TIME)</code>

MYSQL_TYPE_STRING	data length
MYSQL_TYPE_BLOB	data_length

This function was added in MySQL 4.1.2.

Return Values

Return Value	Description
0	Successful, the data has been fetched to application data buffers.
1	Error occurred. Error code and message can be obtained by calling <code>mysql_stmt_errno()</code> and <code>mysql_stmt_error()</code> .
MYSQL_NO_DATA	No more rows/data exists
MYSQL_DATA_TRUNCATED	Data truncation occurred

MYSQL_DATA_TRUNCATED is not returned unless truncation reporting is enabled with `mysql_options()`. To determine which parameters were truncated when this value is returned, check the error members of the MYSQL_BIND parameter structures.

Errors

- CR_COMMANDS_OUT_OF_SYNC
Commands were executed in an improper order.
- CR_OUT_OF_MEMORY
Out of memory.
- CR_SERVER_GONE_ERROR
The MySQL server has gone away.
- CR_SERVER_LOST
The connection to the server was lost during the query.
- CR_UNKNOWN_ERROR
An unknown error occurred.
- CR_UNSUPPORTED_PARAM_TYPE
The buffer type is MYSQL_TYPE_DATE, MYSQL_TYPE_TIME, MYSQL_TYPE_DATETIME, or MYSQL_TYPE_TIMESTAMP, but the data type is not DATE, TIME, DATETIME, or TIMESTAMP.
- All other unsupported conversion errors are returned from `mysql_stmt_bind_result()`.

Example

The following example demonstrates how to fetch data from a table using `mysql_stmt_result_metadata()`, `mysql_stmt_bind_result()`, and `mysql_stmt_fetch()`. (This example expects to retrieve the two rows inserted by the example shown in Section 24.2.7.10, “`mysql_stmt_execute()`”). The `mysql` variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50
```

```
#define SELECT_SAMPLE "SELECT col1, col2, col3, col4 FROM test_table"

MYSQL_STMT      *stmt;

if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
```

24.2.7.14. `mysql_stmt_fetch_column()`

```
int mysql_stmt_fetch_column(MYSQL_STMT *stmt, MYSQL_BIND *bind, unsigned int column, unsigned long offset)
```

Description

Fetch one column from the current result set row. `bind` provides the buffer where data should be placed. It should be set up the same way as for `mysql_stmt_bind_result()`. `column` indicates which column to fetch. The first column is numbered 0. `offset` is the offset within the data value at which to begin retrieving data. This can be used for fetching the data value in pieces. The beginning of the value is offset 0.

This function was added in MySQL 4.1.2.

Return Values

Zero if the value was fetched successfully. Non-zero if an error occurred.

Errors

- `CR_INVALID_PARAMETER_NO`
Invalid column number.
- `CR_NO_DATA`
The end of the result set has already been reached.

24.2.7.15. `mysql_stmt_field_count()`

```
unsigned int mysql_stmt_field_count(MYSQL_STMT *stmt)
```

Description

Returns the number of columns for the most recent statement for the statement handler. This value is zero for statements such as `INSERT` or `DELETE` that do not produce result sets.

`mysql_stmt_field_count()` can be called after you have prepared a statement by invoking `mysql_stmt_prepare()`.

This function was added in MySQL 4.1.3.

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

24.2.7.16. `mysql_stmt_init()`

```
MYSQL_STMT *mysql_stmt_init(MYSQL *mysql)
```

Description

Create a `MYSQL_STMT` handle. The handle should be freed with `mysql_stmt_close(MYSQL_STMT *)`.

This function was added in MySQL 4.1.2.

Return values

A pointer to a `MYSQL_STMT` structure in case of success. `NULL` if out of memory.

Errors

- `CR_OUT_OF_MEMORY`
Out of memory.

24.2.7.17. `mysql_stmt_num_rows()`

```
my_ulonglong mysql_stmt_num_rows(MYSQL_STMT *stmt)
```

Description

Returns the number of rows in the result set.

The use of `mysql_stmt_num_rows()` depends on whether or not you used `mysql_stmt_store_result()` to buffer the entire result set in the statement handle.

If you use `mysql_stmt_store_result()`, `mysql_stmt_num_rows()` may be called immediately.

This function was added in MySQL 4.1.1.

Return Values

The number of rows in the result set.

Errors

None.

24.2.7.18. `mysql_stmt_param_count()`

```
unsigned long mysql_stmt_param_count(MYSQL_STMT *stmt)
```

Description

Returns the number of parameter markers present in the prepared statement.

This function was added in MySQL 4.1.2.

Return Values

An unsigned long integer representing the number of parameters in a statement.

Errors

None.

Example

For the usage of `mysql_stmt_param_count()`, refer to the Example from Section 24.2.7.10, “`mysql_stmt_execute()`”.

24.2.7.19. `mysql_stmt_param_metadata()`

```
MYSQL_RES *mysql_stmt_param_metadata(MYSQL_STMT *stmt)
```

To be added.

This function was added in MySQL 4.1.2.

Description**Return Values****Errors****24.2.7.20. `mysql_stmt_prepare()`**

```
int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *query, unsigned long length)
```

Description

Given the statement handle returned by `mysql_stmt_init()`, prepares the SQL statement pointed to by the string `query` and returns a status value. The string `length` should be given by the `length` argument. The string must consist of a single SQL statement. You should not add a terminating semicolon (;) or \g to the statement.

The application can include one or more parameter markers in the SQL statement by embedding question mark (?) characters into the SQL string at the appropriate positions.

The markers are legal only in certain places in SQL statements. For example, they are allowed in the `VALUES()` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison value. However, they are not allowed for identifiers (such as table or column names), or to specify both operands of a binary operator such as the `=` equal sign. The latter restriction is necessary because it would be impossible to determine the

parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

The parameter markers must be bound to application variables using `mysql_stmt_bind_param()` before executing the statement.

This function was added in MySQL 4.1.2.

Return Values

Zero if the statement was prepared successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

If the prepare operation was unsuccessful (that is, `mysql_stmt_prepare()` returns non-zero), the error message can be obtained by calling `mysql_stmt_error()`.

Example

For the usage of `mysql_stmt_prepare()`, refer to the Example from Section 24.2.7.10, “`mysql_stmt_execute()`”.

24.2.7.21. `mysql_stmt_reset()`

```
my_bool mysql_stmt_reset(MYSQL_STMT *stmt)
```

Description

Reset prepared statement on client and server to state after prepare. This is mainly used to reset data sent with `mysql_stmt_send_long_data()`.

To re-prepare the statement with another query, use `mysql_stmt_prepare()`.

This function was added in MySQL 4.1.1.

Return Values

Zero if the statement was reset successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- CR_SERVER_GONE_ERROR

The MySQL server has gone away.

- CR_SERVER_LOST

The connection to the server was lost during the query

- CR_UNKNOWN_ERROR

An unknown error occurred.

24.2.7.22. `mysql_stmt_result_metadata()`

```
MYSQL_RES *mysql_stmt_result_metadata(MYSQL_STMT *stmt)
```

Description

If a statement passed to `mysql_stmt_prepare()` is one that produces a result set, `mysql_stmt_result_metadata()` returns the result set metadata in the form of a pointer to a `MYSQL_RES` structure that can be used to process the meta information such as total number of fields and individual field information. This result set pointer can be passed as an argument to any of the field-based API functions that process result set metadata, such as:

- `mysql_num_fields()`
- `mysql_fetch_field()`
- `mysql_fetch_field_direct()`
- `mysql_fetch_fields()`
- `mysql_field_count()`
- `mysql_field_seek()`
- `mysql_field_tell()`
- `mysql_free_result()`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysql_free_result()`. This is similar to the way you free a result set obtained from a call to `mysql_store_result()`.

The result set returned by `mysql_stmt_result_metadata()` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with `mysql_stmt_fetch()`.

This function was added in MySQL 4.1.2.

Return Values

A `MYSQL_RES` result structure. `NULL` if no meta information exists for the prepared query.

Errors

- CR_OUT_OF_MEMORY

Out of memory.

- CR_UNKNOWN_ERROR

An unknown error occurred.

Example

For the usage of `mysql_stmt_result_metadata()`, refer to the Example from Section 24.2.7.13, “`mysql_stmt_fetch()`”.

24.2.7.23. `mysql_stmt_row_seek()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_seek(MYSQL_STMT *stmt,
MYSQL_ROW_OFFSET offset)
```

Description

Sets the row cursor to an arbitrary row in a statement result set. The `offset` value is a row offset that should be a value returned from `mysql_stmt_row_tell()` or from `mysql_stmt_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_stmt_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_stmt_row_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

This function was added in MySQL 4.1.1.

Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_stmt_row_seek()`.

Errors

None.

24.2.7.24. `mysql_stmt_row_tell()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_tell(MYSQL_STMT *stmt)
```

Description

Returns the current position of the row cursor for the last `mysql_stmt_fetch()`. This value can be used as an argument to `mysql_stmt_row_seek()`.

You should use `mysql_stmt_row_tell()` only after `mysql_stmt_store_result()`.

This function was added in MySQL 4.1.1.

Return Values

The current offset of the row cursor.

Errors

None.

24.2.7.25. `mysql_stmt_send_long_data()`

```
my_bool mysql_stmt_send_long_data(MYSQL_STMT *stmt, unsigned int
parameter_number, const char *data, unsigned long length)
```

Description

Allows an application to send parameter data to the server in pieces (or ``chunks"). This function can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the TEXT or BLOB data types.

`parameter_number` indicates which parameter to associate the data with. Parameters are numbered beginning with 0. `data` is a pointer to a buffer containing data to be sent, and `length` indicates the number of bytes in the buffer.

Note: The next `mysql_stmt_execute()` call ignores the bind buffer for all parameters that have been used with `mysql_stmt_send_long_data()` since last `mysql_stmt_execute()` or `mysql_stmt_reset()`.

If you want to reset/forget the sent data, you can do it with `mysql_stmt_reset()`. See Section 24.2.7.21, "mysql_stmt_reset()".

This function was added in MySQL 4.1.2.

Return Values

Zero if the data is sent successfully to server. Non-zero if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC
Commands were executed in an improper order.
- CR_SERVER_GONE_ERROR
The MySQL server has gone away.
- CR_OUT_OF_MEMORY
Out of memory.
- CR_UNKNOWN_ERROR
An unknown error occurred.

Example

The following example demonstrates how to send the data for a TEXT column in chunks. It inserts the data value 'MySQL - The most popular Open Source database' into the `text_column` column. The `mysql` variable is assumed to be a valid connection handle.

```
#define INSERT_QUERY "INSERT INTO test_long_data(text_column) VALUES(?)"

MYSQL_BIND bind[1];
long length;

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, "mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_QUERY, strlen(INSERT_QUERY))
{
```

```
    fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}
memset(bind, 0, sizeof(bind));
bind[0].buffer_type= MYSQL_TYPE_STRING;
bind[0].length= &length;
bind[0].is_null= 0;

/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
    fprintf(stderr, "\n param bind failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply data in chunks to server */
if (!mysql_stmt_send_long_data(stmt,0,"MySQL",5))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply the next piece of data */
if (mysql_stmt_send_long_data(stmt,0," - The most popular Open Source database
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Now, execute the query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, "\n mysql_stmt_execute failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}
```

24.2.7.26. `mysql_stmt_sqlstate()`

```
const char *mysql_stmt_sqlstate(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_sqlstate()` returns a null-terminated string containing the SQLSTATE error code for the most recently invoked prepared statement API function that can succeed or fail. The error code consists of five characters. "00000" means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see Chapter 26, *Error Handling in MySQL*.

Note that not all MySQL errors are yet mapped to SQLSTATE's. The value "HY000" (general error) is used for unmapped errors.

This function was added to MySQL 4.1.1.

Return Values

A null-terminated character string containing the SQLSTATE error code.

24.2.7.27. `mysql_stmt_store_result()`

```
int mysql_stmt_store_result(MYSQL_STMT *stmt)
```

Description

You must call `mysql_stmt_store_result()` for every statement that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`), and only if you want to buffer the complete result set by the client, so that the subsequent `mysql_stmt_fetch()` call returns buffered data.

It is unnecessary to call `mysql_stmt_store_result()` for other statements, but if you do, it does not harm or cause any notable performance problem. You can detect whether the statement produced a result set by checking if `mysql_stmt_result_metadata()` returns `NULL`. For more information, refer to Section 24.2.7.22, “`mysql_stmt_result_metadata()`”.

Note: MySQL doesn't by default calculate `MYSQL_FIELD->max_length` for all columns in `mysql_stmt_store_result()` because calculating this would slow down `mysql_stmt_store_result()` considerably and most applications doesn't need `max_length`. If you want `max_length` to be updated, you can call `mysql_stmt_attr_set(MYSQL_STMT, STMT_ATTR_UPDATE_MAX_LENGTH, &flag)` to enable this. See Section 24.2.7.3, “`mysql_stmt_attr_set()`”.

This function was added in MySQL 4.1.0.

Return Values

Zero if the results are buffered successfully. Non-zero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`
Out of memory.
- `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.
- `CR_SERVER_LOST`
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
An unknown error occurred.

24.2.8. C API Prepared statement problems

Here follows a list of the currently known problems with prepared statements:

- `TIME`, `TIMESTAMP`, and `DATETIME` don't support sub seconds (for example from `DATE_FORMAT()`).
- When converting an integer to string, `ZEROFILL` is honored with prepared statements in some cases where the MySQL server doesn't print the leading zeros. (For example, with `MIN(number-with-zerofill)`).
- When converting a floating point number to a string in the client, the value may be slightly different in the last digits.

24.2.9. C API Handling of Multiple Query Execution

From version 4.1, MySQL supports the execution of multiple statements specified in a single query string. To use this capability with a given connection, you must specify the `CLIENT_MULTI_STATEMENTS` option in the flags parameter of `mysql_real_connect()` when opening the connection. You can also set this for an existing connection by calling `mysql_set_server_option(MYSQL_OPTION_MULTI_STATEMENTS_ON)`

By default, `mysql_query()` and `mysql_real_query()` return only the first query status and the subsequent queries status can be processed using `mysql_more_results()` and `mysql_next_result()`.

```
/* Connect to server with option CLIENT_MULTI_STATEMENTS */
mysql_real_connect(..., CLIENT_MULTI_STATEMENTS);

/* Now execute multiple queries */
mysql_query(mysql, "DROP TABLE IF EXISTS test_table;\
CREATE TABLE test_table(id INT);\
INSERT INTO test_table VALUES(10);\
UPDATE test_table SET id=20 WHERE id=10;\
SELECT * FROM test_table;\
DROP TABLE test_table");

do
{
    /* Process all results */
    ...
    printf("total affected rows: %lld", mysql_affected_rows(mysql));
    ...
    if (!(result= mysql_store_result(mysql)))
    {
        printf(stderr, "Got fatal error processing query\n");
        exit(1);
    }
    process_result_set(result); /* client function */
    mysql_free_result(result);
} while (!mysql_next_result(mysql));
```

The multiple-statement capability can be used with `mysql_query()` or `mysql_real_query()`. It cannot be used with the prepared statement interface. Prepared statement handles are defined to work only with strings that contain a single statement.

24.2.10. C API Handling of Date and Time Values

The new binary protocol available in MySQL 4.1 and above allows you to send and receive date and time values (`DATE`, `TIME`, `DATETIME`, and `TIMESTAMP`), using the `MYSQL_TIME` structure. The members of this structure are described in Section 24.2.5, “C API Prepared Statement Data types”.

To send temporal data values, you create a prepared statement with `mysql_stmt_prepare()`. Then, before calling `mysql_stmt_execute()` to execute the statement, use the following procedure to set up each temporal parameter:

1. In the `MYSQL_BIND` structure associated with the data value, set the `buffer_type` member to the type that indicates what kind of temporal value you're sending. For `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` values, set `buffer_type` to `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, respectively.
2. Set the `buffer` member of the `MYSQL_BIND` structure to the address of the `MYSQL_TIME` structure in which you pass the temporal value.
3. Fill in the members of the `MYSQL_TIME` structure that are appropriate for the type of temporal value you're passing.

Use `mysql_stmt_bind_param()` to bind the parameter data to the statement. Then you can call `mysql_stmt_execute()`.

To retrieve temporal values, the procedure is similar, except that you set the `buffer_type` member to the type of value you expect to receive, and the `buffer` member to the address of a `MYSQL_TIME` structure into which the returned value should be placed. Use `mysql_bind_results()` to bind the buffers to the statement after calling `mysql_stmt_execute()` and before fetching the results.

Here is a simple example that inserts `DATE`, `TIME`, and `TIMESTAMP` data. The `mysql` variable is assumed to be a valid connection handle.

```
MYSQL_TIME  ts;
MYSQL_BIND  bind[3];
MYSQL_STMT  *stmt;

strmov(query, "INSERT INTO test_table(date_field, time_field,
                                     timestamp_field) VALUES(?,?,?);");

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(mysql, query, strlen(query)))
{
    fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* set up input buffers for all 3 parameters */
bind[0].buffer_type= MYSQL_TYPE_DATE;
bind[0].buffer= (char *)&ts;
bind[0].is_null= 0;
bind[0].length= 0;
...
bind[1]= bind[2]= bind[0];
...

mysql_stmt_bind_param(stmt, bind);

/* supply the data to be sent in the ts structure */
ts.year= 2002;
ts.month= 02;
ts.day= 03;

ts.hour= 10;
ts.minute= 45;
ts.second= 20;

mysql_stmt_execute(stmt);
..
```

24.2.11. C API Threaded Function Descriptions

You need to use the following functions when you want to create a threaded client. See Section 24.2.15, “How to Make a Threaded Client”.

24.2.11.1. `my_init()`

```
void my_init(void)
```

Description

This function needs to be called once in the program before calling any MySQL function. This initializes some global variables that MySQL needs. If you are using a thread-safe client library, this also calls `mysql_thread_init()` for this thread.

This is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()` and `mysql_connect()`.

Return Values

None.

24.2.11.2. `mysql_thread_init()`

```
my_bool mysql_thread_init(void)
```

Description

This function needs to be called for each created thread to initialize thread-specific variables.

This is automatically called by `my_init()` and `mysql_connect()`.

Return Values

Zero if successful. Non-zero if an error occurred.

24.2.11.3. `mysql_thread_end()`

```
void mysql_thread_end(void)
```

Description

This function needs to be called before calling `pthread_exit()` to free memory allocated by `mysql_thread_init()`.

Note that this function **is not invoked automatically** by the client library. It must be called explicitly to avoid a memory leak.

Return Values

None.

24.2.11.4. `mysql_thread_safe()`

```
unsigned int mysql_thread_safe(void)
```

Description

This function indicates whether the client is compiled as thread-safe.

Return Values

1 is the client is thread-safe, 0 otherwise.

24.2.12. C API Embedded Server Function Descriptions

If you want to allow your application to be linked against the embedded MySQL server library, you must use the `mysql_server_init()` and `mysql_server_end()` functions. See Section 24.2.16, “`libmysqld`, the Embedded MySQL Server Library”.

However, to provide improved memory management, even programs that are linked with `-lmysqlclient` rather than `-lmysqld` should include calls to begin and end use of the library. As of MySQL 4.1.10 and 5.0.3, the `mysql_library_init()` and `mysql_library_end()` functions can be used to do this. These actually are `#define` symbols that make them equivalent to `mysql_server_init()` and `mysql_server_end()`, but the names more clearly indicate that they should be called when beginning and ending use of a MySQL C API library no matter whether the application uses `libmysqlclient` or `libmysqld`. For more information, see Section 24.2.2, “C API Function Overview”.

24.2.12.1. `mysql_server_init()`

```
int mysql_server_init(int argc, char **argv, char **groups)
```

Description

This function **must** be called once in the program using the embedded server before calling any other MySQL function. It starts the server and initializes any subsystems (`mysys`, `InnoDB`, etc.) that the server uses. If this function is not called, the next call to `mysql_init()` executes `mysql_server_init()`. If you are using the `DEBUG` package that comes with MySQL, you should call this after you have called `my_init()`.

The `argc` and `argv` arguments are analogous to the arguments to `main()`. The first element of `argv` is ignored (it typically contains the program name). For convenience, `argc` may be 0 (zero) if there are no command-line arguments for the server. `mysql_server_init()` makes a copy of the arguments so it's safe to destroy `argv` or `groups` after the call.

If you want to connect to an external server without starting the embedded server, you have to specify a negative value for `argc`.

The `NULL`-terminated list of strings in `groups` selects which groups in the option files are active. See Section 4.3.2, “Using Option Files”. For convenience, `groups` may be `NULL`, in which case the `[server]` and `[embedded]` groups are active.

Example

```
#include <mysql.h>
#include <stdlib.h>

static char *server_args[] = {
    "this_program",          /* this string is not used */
    "--datadir=.",
    "--key_buffer_size=32M"
};
static char *server_groups[] = {
    "embedded",
    "server",
    "this_program_SERVER",
    (char *)NULL
};

int main(void) {
    if (mysql_server_init(sizeof(server_args) / sizeof(char *),
                          server_args, server_groups))
        exit(1);

    /* Use any MySQL API functions here */

    mysql_server_end();

    return EXIT_SUCCESS;
}
```

Return Values

0 if okay, 1 if an error occurred.

24.2.12.2. `mysql_server_end()`

```
void mysql_server_end(void)
```

Description

This function **must** be called once in the program after all other MySQL functions. It shuts down the embedded server.

Return Values

None.

24.2.13. Common questions and problems when using the C API

24.2.13.1. Why `mysql_store_result()` Sometimes Returns NULL After `mysql_query()` Returns Success

It is possible for `mysql_store_result()` to return NULL following a successful call to `mysql_query()`. When this happens, it means one of the following conditions occurred:

- There was a `malloc()` failure (for example, if the result set was too large).
- The data couldn't be read (an error occurred on the connection).
- The query returned no data (for example, it was an INSERT, UPDATE, or DELETE).

You can always check whether the statement should have produced a non-empty result by calling `mysql_field_count()`. If `mysql_field_count()` returns zero, the result is empty and the last query was a statement that does not return values (for example, an INSERT or a DELETE). If `mysql_field_count()` returns a non-zero value, the statement should have produced a non-empty result. See the description of the `mysql_field_count()` function for an example.

You can test for an error by calling `mysql_error()` or `mysql_errno()`.

24.2.13.2. What Results You Can Get from a Query

In addition to the result set returned by a query, you can also get the following information:

- `mysql_affected_rows()` returns the number of rows affected by the last query when doing an INSERT, UPDATE, or DELETE.

In MySQL 3.23, there is an exception when DELETE is used without a WHERE clause. In this case, the table is re-created as an empty table and `mysql_affected_rows()` returns zero for the number of records affected. In MySQL 4.0, DELETE always returns the correct number of rows deleted. For a fast recreate, use TRUNCATE TABLE.

- `mysql_num_rows()` returns the number of rows in a result set. With `mysql_store_result()`, `mysql_num_rows()` may be called as soon as `mysql_store_result()` returns. With `mysql_use_result()`, `mysql_num_rows()` may be called only after you have fetched all the rows with `mysql_fetch_row()`.
- `mysql_insert_id()` returns the ID generated by the last query that inserted a row into a table with an AUTO_INCREMENT index. See Section 24.2.3.33, “`mysql_insert_id()`”.

- Some queries (`LOAD DATA INFILE ...`, `INSERT INTO ... SELECT ...`, `UPDATE`) return additional information. The result is returned by `mysql_info()`. See the description for `mysql_info()` for the format of the string that it returns. `mysql_info()` returns a `NULL` pointer if there is no additional information.

24.2.13.3. How to Get the Unique ID for the Last Inserted Row

If you insert a record into a table that contains an `AUTO_INCREMENT` column, you can obtain the value stored into that column by calling the `mysql_insert_id()` function.

You can check from your C applications whether a value was stored into an `AUTO_INCREMENT` column by executing the following code (which assumes that you've checked that the statement succeeded). It determines whether the query was an `INSERT` with an `AUTO_INCREMENT` index:

```
if ((result = mysql_store_result(&mysql)) == 0 &&
    mysql_field_count(&mysql) == 0 &&
    mysql_insert_id(&mysql) != 0)
{
    used_id = mysql_insert_id(&mysql);
}
```

For more information, see Section 24.2.3.33, “`mysql_insert_id()`”.

When a new `AUTO_INCREMENT` value has been generated, you can also obtain it by executing a `SELECT LAST_INSERT_ID()` statement with `mysql_query()` and retrieving the value from the result set returned by the statement.

For `LAST_INSERT_ID()`, the most recently generated ID is maintained in the server on a per-connection basis. It is not changed by another client. It is not even changed if you update another `AUTO_INCREMENT` column with a non-magic value (that is, a value that is not `NULL` and not 0).

If you want to use the ID that was generated for one table and insert it into a second table, you can use SQL statements like this:

```
INSERT INTO foo (auto,text)
    VALUES(NULL,'text');           # generate ID by inserting NULL
INSERT INTO foo2 (id,text)
    VALUES(LAST_INSERT_ID(),'text'); # use ID in second table
```

Note that `mysql_insert_id()` returns the value stored into an `AUTO_INCREMENT` column, whether that value is automatically generated by storing `NULL` or 0 or was specified as an explicit value. `LAST_INSERT_ID()` returns only automatically generated `AUTO_INCREMENT` values. If you store an explicit value other than `NULL` or 0, it does not affect the value returned by `LAST_INSERT_ID()`.

24.2.13.4. Problems Linking with the C API

When linking with the C API, the following errors may occur on some systems:

```
gcc -g -o client test.o -L/usr/local/lib/mysql -lmysqlclient -lsocket -lnsl
Undefined          first referenced
 symbol            in file
floor              /usr/local/lib/mysql/libmysqlclient.a(password.o)
ld: fatal: Symbol referencing errors. No output written to client
```

If this happens on your system, you must include the math library by adding `-lm` to the end of the compile/link line.

24.2.14. Building Client Programs

If you compile MySQL clients that you've written yourself or that you obtain from a third-party, they must be linked using the `-lmysqlclient -lz` option on the link command. You may also need to specify a `-L` option to tell the linker where to find the library. For example, if the library is installed in `/usr/local/mysql/lib`, use `-L/usr/local/mysql/lib -lmysqlclient -lz` on the link command.

For clients that use MySQL header files, you may need to specify a `-I` option when you compile them (for example, `-I/usr/local/mysql/include`), so the compiler can find the header files.

To make it simpler to compile MySQL programs on Unix, we have provided the `mysql_config` script for you. See Section 24.1.2, “`mysql_config`. Get compile options for compiling clients”.

You can use it to compile a MySQL client as follows:

```
CFG=/usr/local/mysql/bin/mysql_config
sh -c "gcc -o progname ` $CFG --cflags ` progname.c ` $CFG --libs `"
```

The `sh -c` is needed to get the shell not to treat the output from `mysql_config` as one word.

24.2.15. How to Make a Threaded Client

The client library is almost thread-safe. The biggest problem is that the subroutines in `net.c` that read from sockets are not interrupt safe. This was done with the thought that you might want to have your own alarm that can break a long read to a server. If you install interrupt handlers for the `SIGPIPE` interrupt, the socket handling should be thread-safe.

New in 4.0.16: To not abort the program when a connection terminates, MySQL blocks `SIGPIPE` on the first call to `mysql_server_init()`, `mysql_init()` or `mysql_connect()`. If you want to have your own `SIGPIPE` handler, you should first call `mysql_server_init()` and then install your handler. In older versions of MySQL `SIGPIPE` was blocked, but only in the thread safe client library, for every call to `mysql_init()`.

In the older binaries we distribute on our Web site (<http://www.mysql.com/>), the client libraries are not normally compiled with the thread-safe option (the Windows binaries are by default compiled to be thread-safe). Newer binary distributions should have both a normal and a thread-safe client library.

To get a threaded client where you can interrupt the client from other threads and set timeouts when talking with the MySQL server, you should use the `-lmysys`, `-lmystrings`, and `-ldbbug` libraries and the `net_serv.o` code that the server uses.

If you don't need interrupts or timeouts, you can just compile a thread-safe client library (`mysqlclient_r`) and use this. See Section 24.2, “MySQL C API”. In this case, you don't have to worry about the `net_serv.o` object file or the other MySQL libraries.

When using a threaded client and you want to use timeouts and interrupts, you can make great use of the routines in the `thr_alarm.c` file. If you are using routines from the `mysys` library, the only thing you must remember is to call `my_init()` first! See Section 24.2.11, “C API Threaded Function Descriptions”.

All functions except `mysql_real_connect()` are by default thread-safe. The following notes describe how to compile a thread-safe client library and use it in a thread-safe manner. (The notes below for `mysql_real_connect()` actually apply to `mysql_connect()` as well, but because `mysql_connect()` is deprecated, you should be using `mysql_real_connect()` anyway.)

To make `mysql_real_connect()` thread-safe, you must recompile the client library with this command:

```
shell> ./configure --enable-thread-safe-client
```

This creates a thread-safe client library `libmysqlclient_r`. (Assuming that your OS has a thread-safe `gethostbyname_r()` function.) This library is thread-safe per connection. You can let two threads share the same connection with the following caveats:

- Two threads can't send a query to the MySQL server at the same time on the same connection. In particular, you have to ensure that between a `mysql_query()` and `mysql_store_result()` no other thread is using the same connection.
- Many threads can access different result sets that are retrieved with `mysql_store_result()`.
- If you use `mysql_use_result`, you have to ensure that no other thread is using the same connection until the result set is closed. However, it really is best for threaded clients that share the same connection to use `mysql_store_result()`.
- If you want to use multiple threads on the same connection, you must have a mutex lock around your `mysql_query()` and `mysql_store_result()` call combination. Once `mysql_store_result()` is ready, the lock can be released and other threads may query the same connection.
- If you program with POSIX threads, you can use `pthread_mutex_lock()` and `pthread_mutex_unlock()` to establish and release a mutex lock.

You need to know the following if you have a thread that is calling MySQL functions which did not create the connection to the MySQL database:

When you call `mysql_init()` or `mysql_connect()`, MySQL creates a thread-specific variable for the thread that is used by the debug library (among other things).

If you call a MySQL function, before the thread has called `mysql_init()` or `mysql_connect()`, the thread does not have the necessary thread-specific variables in place and you are likely to end up with a core dump sooner or later.

The get things to work smoothly you have to do the following:

1. Call `my_init()` at the start of your program if it calls any other MySQL function before calling `mysql_real_connect()`.
2. Call `mysql_thread_init()` in the thread handler before calling any MySQL function.
3. In the thread, call `mysql_thread_end()` before calling `pthread_exit()`. This frees the memory used by MySQL thread-specific variables.

You may get some errors because of undefined symbols when linking your client with `libmysqlclient_r`. In most cases this is because you haven't included the thread libraries on the link/compile line.

24.2.16. libmysqld, the Embedded MySQL Server Library

24.2.16.1. Overview of the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server

available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change an old threaded application to use the embedded library, you normally only have to add calls to the following functions:

Function	When to Call
<code>mysql_server_init()</code>	Should be called before any other MySQL function is called, preferably early in the <code>main()</code> function.
<code>mysql_server_end()</code>	Should be called before your program exits.
<code>mysql_thread_init()</code>	Should be called in each thread you create that accesses MySQL.
<code>mysql_thread_end()</code>	Should be called before calling <code>pthread_exit()</code>

Then you must link your code with `libmysqld.a` instead of `libmysqlclient.a`.

The `mysql_server_xxx()` functions are also included in `libmysqlclient.a` to allow you to change between the embedded and the client/server version by just linking your application with the right library. See Section 24.2.12.1, “`mysql_server_init()`”.

24.2.16.2. Compiling Programs with `libmysqld`

To get a `libmysqld` library you should configure MySQL with the `-with-embedded-server` option.

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

24.2.16.3. Restrictions when using the Embedded MySQL Server

The embedded server has the following limitations:

- No support for ISAM tables. (This is mainly done to make the library smaller)
- No user-defined functions (UDFs).
- No stack trace on core dump.
- No internal RAID support. (This is not normally needed as most current operating systems support big files).
- You cannot set this up as a master or a slave (no replication).
- You can't connect to an embedded server from an outside process with sockets or TCP/IP.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

24.2.16.4. Using Option Files with the Embedded Server

The following is the recommended way to use option files to make it easy to switch between a client/server application and one where MySQL is embedded. See Section 4.3.2, “Using Option Files”.

- Put common options in the [server] section. These are read by both MySQL versions.
- Put client/server-specific options in the [mysqld] section.
- Put embedded MySQL-specific options in the [embedded] section.
- Put application-specific options in a [ApplicationName_SERVER] section.

24.2.16.5. Things left to do in Embedded Server (TODO)

- We are going to provide options to leave out some parts of MySQL to make the library smaller.
- There is still a lot of speed optimization to do.
- Errors are written to `stderr`. We will add an option to specify a filename for these.
- We have to change InnoDB to not be so verbose when using in the embedded version.

24.2.16.6. A Simple Embedded Server Example

This example program and makefile should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed. This example is designed to give enough details to understand the problem, without the clutter that is a necessary part of a real application.

To try out the example, create an `test_libmysqld` directory at the same level as the `mysql-4.0` source directory. Save the `test_libmysqld.c` source and the GNUmakefile in the directory, and run GNU make from inside the `test_libmysqld` directory.

```
test_libmysqld.c

/*
 * A simple example client, using the embedded MySQL server library
 */

#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>

MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);

const char *server_groups[] = {
    "test_libmysqld_SERVER", "embedded", "server", NULL
};

int
main(int argc, char **argv)
{
    MYSQL *one, *two;

    /* mysql_server_init() must be called before any other mysql
     * functions.
     *
     * You can use mysql_server_init(0, NULL, NULL), and it
     * initializes the server using groups = {
     *   "server", "embedded", NULL
     * }.
     *
     * In your $HOME/.my.cnf file, you probably want to put:
```

```
[test_libmysqld_SERVER]
language = /path/to/source/of/mysql/sql/share/english

    * You could, of course, modify argc and argv before passing
    * them to this function.  Or you could create new ones in any
    * way you like.  But all of the arguments in argv (except for
    * argv[0], which is the program name) should be valid options
    * for the MySQL server.
    *
    * If you link this client against the normal mysqlclient
    * library, this function is just a stub that does nothing.
    */
mysql_server_init(argc, argv, (char **)server_groups);

one = db_connect("test");
two = db_connect(NULL);

db_do_query(one, "SHOW TABLE STATUS");
db_do_query(two, "SHOW DATABASES");

mysql_close(two);
mysql_close(one);

/* This must be called after all other mysql functions */
mysql_server_end();

exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)
{
    va_list ap;
    va_start(ap, fmt);
    vfprintf(stderr, fmt, ap);
    va_end(ap);
    (void)putc('\n', stderr);
    if (db)
        db_disconnect(db);
    exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
    MYSQL *db = mysql_init(NULL);
    if (!db)
        die(db, "mysql_init failed: no memory");
    /*
     * Notice that the client and server use separate group names.
     * This is critical, because the server does not accept the
     * client's options, and vice versa.
     */
    mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test_libmysqld_CLIENT");
    if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
        die(db, "mysql_real_connect failed: %s", mysql_error(db));

    return db;
}

void
db_disconnect(MYSQL *db)
{
    mysql_close(db);
}

void
db_do_query(MYSQL *db, const char *query)
{

```

```

if (mysql_query(db, query) != 0)
    goto err;

if (mysql_field_count(db) > 0)
{
    MYSQL_RES    *res;
    MYSQL_ROW    row, end_row;
    int num_fields;

    if (!(res = mysql_store_result(db)))
        goto err;
    num_fields = mysql_num_fields(res);
    while ((row = mysql_fetch_row(res)))
    {
        (void)fputs(">> ", stdout);
        for (end_row = row + num_fields; row < end_row; ++row)
            (void)printf("%s\t", row ? (char*)*row : "NULL");
        (void)fputc('\n', stdout);
    }
    (void)fputc('\n', stdout);
    mysql_free_result(res);
}
else
    (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));

return;

err:
die(db, "db_do_query failed: %s [%s]", mysql_error(db), query);
}

```

GNUmakefile

```

# This assumes the MySQL software is installed in /usr/local/mysql
inc      := /usr/local/mysql/include/mysql
lib      := /usr/local/mysql/lib

# If you have not installed the MySQL software yet, try this instead
#inc     := $(HOME)/mysql-4.0/include
#lib     := $(HOME)/mysql-4.0/libmysqld

CC       := gcc
CPPFLAGS := -I$(inc) -D_THREAD_SAFE -D_REENTRANT
CFLAGS  := -g -W -Wall
LDFLAGS := -static
# You can change -lmysqld to -lmysqlclient to use the
# client/server library
LDLIBS  = -L$(lib) -lmysqld -lz -lm -lcrypt

ifneq (,$(shell grep FreeBSD /COPYRIGHT 2>/dev/null))
# FreeBSD
LDFLAGS += -pthread
else
# Assume Linux
LDLIBS += -lpthread
endif

# This works for simple one-file test programs
sources := $(wildcard *.c)
objects := $(patsubst %c,%o,$(sources))
targets := $(basename $(sources))

all: $(targets)

clean:
    rm -f $(targets) $(objects) *.core

```

24.2.16.7. Licensing the Embedded Server

We encourage everyone to promote free software by releasing code under the GPL or a compatible license. For those who are not able to do this, another option is to purchase a commercial license for the MySQL code from MySQL AB. For details, please see <http://www.mysql.com/company/legal/licensing/>.

24.3. MySQL PHP API

PHP is a server-side, HTML-embedded scripting language that may be used to create dynamic Web pages. It is available for most operating systems and Web servers, and can access most common databases, including MySQL. PHP may be run as a separate program or compiled as a module for use with the Apache Web server.

PHP actually provides two different MySQL API extensions:

- **mysql** - Available for PHP versions 4 and 5, this extension is intended for use with MySQL versions prior to MySQL 4.1. This extension does not support the improved authentication protocol used in MySQL 4.1.1 and later, nor does it support prepared statements or multiple statements. If you wish to use this extension with MySQL 4.1 and more recent versions of MySQL, you will likely want to configure the MySQL server to use the **--old-passwords** option (see Section A.2.3, "Client does not support authentication protocol"). This extension is documented on the PHP Website at <http://php.net/mysql>.
- **mysqli** - Stands for "MySQL, Improved", this extension is available only in PHP 5. It is intended for use with MySQL 4.1.1 and later. This extension fully supports the authentication protocol used in MySQL 4.1.1 and subsequent MySQL releases as well as the Prepared Statements and Multiple Statements APIs. In addition, this extension provides an advanced, object-oriented programming interface. You can read the documentation for the **mysqli** extension at <http://php.net/mysqli>. A helpful article can be found at <http://www.zend.com/php5/articles/php5-mysqli.php>.

The PHP distribution and documentation are available from the PHP Website [<http://www.php.net/>].

24.3.1. Common Problems with MySQL and PHP

- Error: "Maximum Execution Time Exceeded" This is a PHP limit; go into the `php.ini` file and set the maximum execution time up from 30 seconds to something higher, as needed. It is also not a bad idea to double the RAM allowed per script to 16MB instead of 8MB.
- Error: "Fatal error: Call to unsupported or undefined function mysql_connect() in .." This means that your PHP version isn't compiled with MySQL support. You can either compile a dynamic MySQL module and load it into PHP or recompile PHP with built-in MySQL support. This is described in detail in the PHP manual.
- Error: "undefined reference to `uncompress'" This means that the client library is compiled with support for a compressed client/server protocol. The fix is to add `-lz` last when linking with `-lmysqlclient`.
- Error: "Client does not support authentication protocol" This is most often encountered when trying to use the older **mysql** extension with MySQL 4.1.1 and later. Possible solutions are: downgrade to MySQL 4.0; switch to PHP 5 and the newer **mysqli** extension; or configure the MySQL server with **--old-passwords**. (See Section A.2.3, "Client does not support authentication protocol", for more information.)

24.4. MySQL Perl API

The Perl DBI module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI, you must install the DBI module, as well as a DataBase Driver (DBD) module for each type of server you want to access. For MySQL, this driver is the `DBD::mysql` module.

Perl DBI is the recommended Perl interface. It replaces an older interface called `mysqlperl`, which should be considered obsolete.

Installation instructions for Perl DBI support are given in Section 2.13, “Perl Installation Notes”.

DBI information is available at the command line, online, or in printed form:

- Once you have the DBI and `DBD::mysql` modules installed, you can get information about them at the command line with the `perldoc` command:

```
shell> perldoc DBI
shell> perldoc DBI::FAQ
shell> perldoc DBD::mysql
```

You can also use `pod2man`, `pod2html`, and so forth to translate this information into other formats.

- For online information about Perl DBI, visit the DBI Web site, <http://dbi.perl.org/>. That site hosts a general DBI mailing list. MySQL AB hosts a list specifically about `DBD::mysql`; see Section 1.6.1.1, “The MySQL Mailing Lists”.
- For printed information, the official DBI book is *Programming the Perl DBI* (Alligator Descartes and Tim Bunce, O'Reilly & Associates, 2000). Information about the book is available at the DBI Web site, <http://dbi.perl.org/>.

For information that focuses specifically on using DBI with MySQL, see *MySQL and Perl for the Web* (Paul DuBois, New Riders, 2001). This book's Web site is <http://www.kitebird.com/mysql-perl/>.

24.5. MySQL C++ API

`MySQL++` is a MySQL API for C++. Warren Young has taken over this project. More information can be found at <http://www.mysql.com/products/mysql++/>.

24.5.1. Borland C++

You can compile the MySQL Windows source with Borland C++ 5.02. (The Windows source includes only projects for Microsoft VC++, for Borland C++ you have to do the project files yourself.)

One known problem with Borland C++ is that it uses a different structure alignment than VC++. This means that you run into problems if you try to use the default `libmysql.dll` libraries (that were compiled with VC++) with Borland C++. To avoid this problem, only call `mysql_init()` with `NULL` as an argument, not a pre-allocated `MYSQL` structure.

24.6. MySQL Python API

`MySQLdb` provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at <http://sourceforge.net/projects/mysql-python/>.

24.7. MySQL Tcl API

`MySQLtcl` is a simple API for accessing a MySQL database server from the Tcl programming lan-

guage. It can be found at <http://www.xdobry.de/mysqltcl/>.

24.8. MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the Eiffel programming language, written by Michael Ravits. It can be found at <http://efsa.sourceforge.net/archive/ravits/mysql.htm>.

Chapter 25. MySQL Connectors

This chapter describes MySQL Connectors, drivers that provide connectivity to the MySQL server for client programs.

25.1. MySQL ODBC Support

MySQL provides support for ODBC by means of MySQL Connector/ODBC, the family of MyODBC drivers. This is the reference for the Connector/ODBC product family of MyODBC drivers that provide ODBC 3.5x compliant access to the MySQL Database System. It teaches you how to install MyODBC and how to use it. There is also information about common programs that are known to work with MyODBC and answers to some of the most frequently asked questions about MyODBC.

This reference applies to MyODBC 3.51. You can find a manual for an older version of MyODBC in the binary or source distribution for that version.

This is a reference to the MySQL ODBC drivers, not a general ODBC reference. For more information about ODBC, refer to <http://www.microsoft.com/data/>.

The application development part of this reference assumes a good working knowledge of C, general DBMS knowledge, and finally, but not least, familiarity with MySQL. For more information about MySQL functionality and its syntax, refer to <http://dev.mysql.com/doc/>.

If you have questions that are not answered in this document, please send a mail message to myodbc@lists.mysql.com.

25.1.1. Introduction to MyODBC

25.1.1.1. What is ODBC?

ODBC (Open Database Connectivity) provides a way for client programs to access a wide range of databases or data sources. ODBC is a standardized API that allows connections to SQL database servers. It was developed according to the specifications of the SQL Access Group and defines a set of function calls, error codes, and data types that can be used to develop database-independent applications. ODBC usually is used when database independence or simultaneous access to different data sources is required.

For more information about ODBC, refer to <http://www.microsoft.com/data/>.

25.1.1.2. What is Connector/ODBC?

Connector/ODBC is the term designating the MySQL AB product family of MySQL ODBC drivers. These are known as the MyODBC drivers.

25.1.1.3. What is MyODBC 2.50?

MyODBC 2.50 is a 32-bit ODBC driver from MySQL AB that is based on ODBC 2.50 specification level 0 (with level 1 and 2 features). This is one of the most popular ODBC drivers in the Open Source market, used by many users to access the MySQL functionality.

25.1.1.4. What is MyODBC 3.51?

MyODBC 3.51 is a 32-bit ODBC driver, also known as the MySQL ODBC 3.51 driver. This version is enhanced compared to the existing MyODBC 2.50 driver. It has support for ODBC 3.5x specification level 1 (complete core API + level 2 features) in order to continue to provide all functionality of ODBC for accessing MySQL.

25.1.1.5. Where to Get MyODBC

MySQL AB distributes all its products under the General Public License (GPL). You can get a copy of the latest version of MyODBC binaries and sources from the MySQL AB Web site <http://dev.mysql.com/downloads/>.

For more information about MyODBC, visit <http://www.mysql.com/products/myodbc/>.

For more information about licensing, visit <http://www.mysql.com/company/legal/licensing/>.

25.1.1.6. Supported Platforms

MyODBC can be used on all major platforms supported by MySQL, such as:

- Windows 95, 98, Me, NT, 2000, XP, and 2003
- All Unix Operating Systems
 - AIX
 - Amiga
 - BSDI
 - DEC
 - FreeBSD
 - HP-UX 10, 11
 - Linux
 - Mac OS X Server
 - Mac OS X
 - NetBSD
 - OpenBSD
 - OS/2
 - SGI Irix
 - Solaris
 - SunOS
 - SCO OpenServer
 - SCO UnixWare
 - Tru64 Unix

If a binary distribution is not available for downloading for a particular platform, you can build the driver yourself by downloading the driver sources. You can contribute the binaries to MySQL by sending a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com), so that it becomes available for other users.

25.1.1.7. MyODBC Mailing List

MySQL AB provides assistance to the user community by means of its mailing lists. For MyODBC-related issues, you can get help from experienced users by using the [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com) mailing list.

For information about subscribing to MySQL mailing lists or to browse list archives, visit <http://lists.mysql.com/>.

Of particular interest is the ODBC forum in the MySQL Connectors section of the forums.

25.1.1.8. MyODBC Forum

Community support from experienced users is available through the MySQL Forums, located at <http://forums.mysql.com>.

25.1.1.9. How to Report MyODBC Problems or Bugs

If you encounter difficulties or problems with MyODBC, you should start by making a log file from the ODBC Manager (the log you get when requesting logs from ODBC ADMIN) and MyODBC. The procedure for doing this is described in Section 25.1.9.7, “Getting an ODBC Trace File”.

Check the MyODBC trace file to find out what could be wrong. You should be able to determine what statements were issued by searching for the string `>mysql_real_query` in the `myodbc.log` file.

You should also try issuing the statements from the **mysql** client program or from `admndemo`. This helps you determine whether the error is in MyODBC or MySQL.

If you find out something is wrong, please only send the relevant rows (maximum 40 rows) to the `myodbc` mailing list. See Section 1.6.1.1, “The MySQL Mailing Lists”. Please never send the whole MyODBC or ODBC log file!

If you are unable to find out what's wrong, the last option is to create an archive in **tar** or Zip format that contains a MyODBC trace file, the ODBC log file, and a `README` file that explains the problem. You can send this to <ftp://ftp.mysql.com/pub/mysql/upload/>. Only we at MySQL AB has access to the files you upload, and we are very discreet with the data.

If you can create a program that also demonstrates the problem, please include it in the archive as well.

If the program works with some other SQL server, you should include an ODBC log file where you do exactly the same thing in the other SQL server.

Remember that the more information you can supply to us, the more likely it is that we can fix the problem.

25.1.1.10. How to Submit a MyODBC Patch

You can send a patch or suggest a better solution for any existing code or problems by sending a mail message to `<myodbc@lists.mysql.com>`.

25.1.2. General Information About ODBC and MyODBC

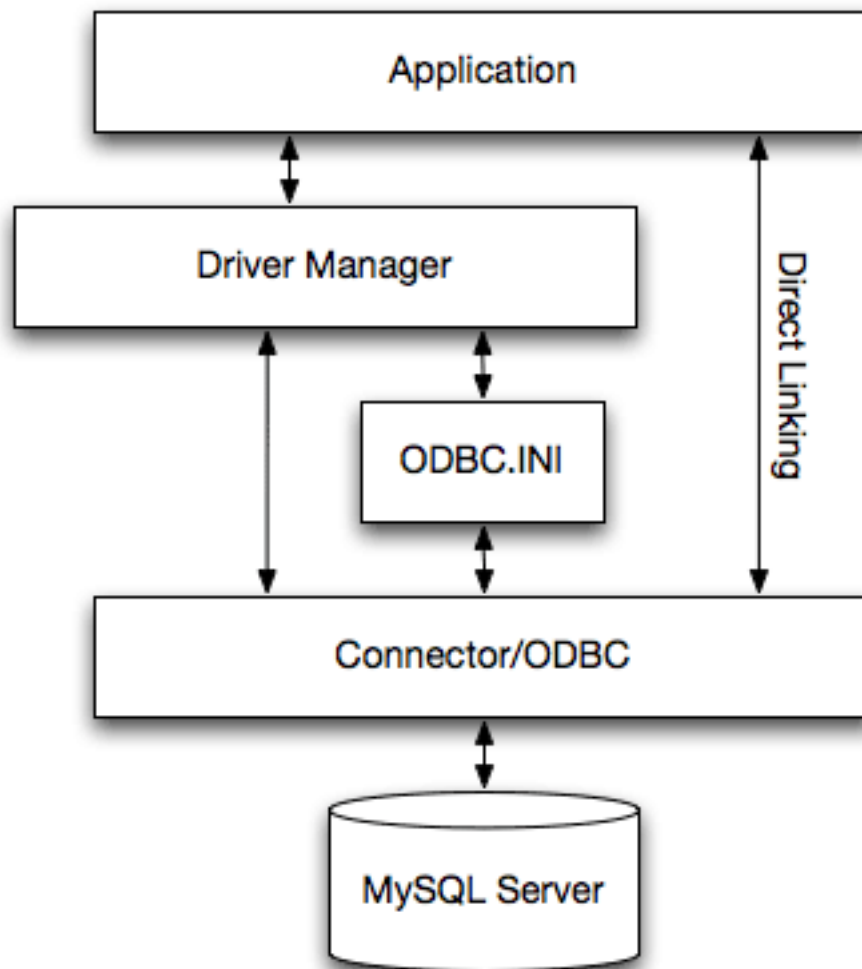

25.1.2.1. Introduction to ODBC

Open Database Connectivity (ODBC) is a widely accepted application-programming interface (API) for database access. It is based on the Call-Level Interface (CLI) specifications from X/Open and ISO/IEC for database APIs and uses Structured Query Language (SQL) as its database access language.

A survey of ODBC functions supported by MyODBC is given at Section 25.1.16, “MyODBC API Reference”. For general information about ODBC, see <http://www.microsoft.com/data/>.

25.1.2.2. MyODBC Architecture

The MyODBC architecture is based on five components, as shown in the following diagram:

- **Application:**

An application is a program that calls the ODBC API to access the data from the MySQL server. The Application communicates with the Driver Manager using the standard ODBC calls. The Application does not care where the data is stored, how it is stored, or even how the system is configured to access the data. It needs to know only the Data Source Name (DSN).

A number of tasks are common to all applications, no matter how they use ODBC. These tasks are:

- Selecting the MySQL server and connecting to it
- Submitting SQL statements for execution
- Retrieving results (if any)
- Processing errors
- Committing or rolling back the transaction enclosing the SQL statement
- Disconnecting from the MySQL server

Because most data access work is done with SQL, the primary tasks for applications that use ODBC are submitting SQL statements and retrieving any results generated by those statements.

- **Driver manager:**

The Driver Manager is a library that manages communication between application and driver or drivers. It performs the following tasks:

- Resolves Data Source Names (DSN)
- Driver loading and unloading
- Processes ODBC function calls or passes them to the driver

- **MyODBC Driver:**

The MyODBC driver is a library that implements the functions in the ODBC API. It processes ODBC function calls, submits SQL requests to MySQL server, and returns results back to the application. If necessary, the driver modifies an application's request so that the request conforms to syntax supported by the MySQL.

- **ODBC.INI:**

ODBC.INI is the ODBC configuration file that stores the driver and database information required to connect to the server. It is used by the Driver Manager to determine which driver to be loaded using the Data Source Name. The driver uses this to read connection parameters based on the DSN specified. For more information, Section 25.1.9, “MyODBC Configuration”.

- **MySQL Server:**

The MySQL server is the source of data. MySQL is:

- A database management system (DBMS)
- A relational database management system (RDBMS)
- Open Source Software

25.1.2.3. ODBC Driver Managers

An ODBC Driver Manager is a library that manages communication between the ODBC aware application and driver(s). Its main functionality includes:

- Resolving Data Source Names (DSN)
- Driver loading and unloading
- Processing ODBC function calls or passing them to the driver

The following driver managers are commonly used:

- Microsoft Windows ODBC Driver Manager (`odbc32.dll`), <http://www.microsoft.com/data/>
- unixODBC Driver Manager for Unix (`libodbc.so`), <http://www.unixodbc.org>.
- iODBC ODBC Driver Manager for Unix (`libiodbc.so`), <http://www.iodbc.org>

MyODBC 3.51 also is shipped with UnixODBC beginning with version 2.1.2.

25.1.2.4. Types of MySQL ODBC Drivers

MySQL AB supports two Open Source ODBC drivers for accessing MySQL functionality through the ODBC API: MyODBC (MyODBC 2.50) and MySQL ODBC 3.51 Driver (MyODBC 3.51).

Note: From this section onward, we refer both the drivers generically as MyODBC. Whenever there is a difference, we use the original names.

25.1.3. How to Install MyODBC

MyODBC works on Windows 9x, Me, NT, 2000, XP, and 2003, and on most Unix platforms.

MyODBC is Open Source. You can find the newest version at <http://dev.mysql.com/downloads/connector/odbc/>. Please note that the 2.50.x versions are LGPL licensed, whereas the 3.51.x versions are GPL licensed.

If you have problem with MyODBC and your program also works with OLEDB, you should try the OLEDB driver.

Normally you need to install MyODBC only on Windows machines. You need MyODBC for Unix only if you have a program like ColdFusion that is running on a Unix machine and uses ODBC to connect for database access.

If you want to install MyODBC on a Unix box, you also need an ODBC manager. MyODBC is known to work with most Unix ODBC managers.

- To make a connection to a Unix box from a Windows box with an ODBC application (one that doesn't support MySQL natively), you must first install MyODBC on the Windows machine.
- The user and Windows machine must have access privileges for the MySQL server on the Unix machine. This is set up with the GRANT command. See Section 13.5.1.3, "GRANT and REVOKE Syntax".
- You must create an ODBC DSN entry as follows:
 1. Open the Control Panel on the Windows machine.
 2. Double-click the ODBC Data Sources 32-bit icon.
 3. Click the tab User DSN.
 4. Click the Add button.
 5. Select MySQL in the screen Create New Data Source and click the Finish button.
 6. The MySQL Driver default configuration screen is shown. See Section 25.1.9.2, "Configuring a MyODBC DSN on Windows".
- Start your application and select the ODBC driver with the DSN that you specified in the ODBC administrator.

Notice that other configuration options are shown on the MySQL screen that you can try if you run into problems (options such as trace, don't prompt on connect, and so forth).

25.1.4. Installing MyODBC from a Binary Distribution on Windows

To install MyODBC on Windows, you should download the appropriate distribution file from <http://dev.mysql.com/downloads/connector/odbc/>, unpack it, and execute the **MyODBC-VERSION.exe** file.

On Windows, you may get the following error when trying to install the older MyODBC 2.50 driver:

```
An error occurred while copying C:\WINDOWS\SYSTEM\MFC30.DLL. Restart
Windows and try installing again (before running any applications
which use ODBC)
```

The problem is that some other program is using ODBC. Because of how Windows is designed, you may not be able in this case to install new ODBC drivers with Microsoft's ODBC setup program. In most cases, you can continue by pressing Ignore to copy the rest of the MyODBC files and the final installation should still work. If it doesn't, the solution is to re-boot your computer in "safe mode." Choose safe mode by pressing F8 just before your machine starts Windows during re-booting, install MyODBC, and re-boot to normal mode.

25.1.5. Installing MyODBC from a Binary Distribution on Unix

25.1.5.1. Installing MyODBC from an RPM Distribution

To install or upgrade MyODBC from an RPM distribution on Linux, simply download the RPM distribution of the latest version of MyODBC and follow the instructions below. Use **su root** to become root, then install the RPM file.

If you are installing for the first time:

```
shell> su root
shell> rpm -ivh MyODBC-3.51.01.i386-1.rpm
```

If the driver exists, upgrade it like this:

```
shell> su root
shell> rpm -Uvh MyODBC-3.51.01.i386-1.rpm
```

If there is any dependency error for MySQL client library, `libmysqlclient`, simply ignore it by supplying the `--nodeps` option, and then make sure the MySQL client shared library is in the path or set through `LD_LIBRARY_PATH`.

This installs the driver libraries and related documents to `/usr/local/lib` and `/usr/share/doc/MyODBC` respectively. Proceed onto Section 25.1.9.3, "Configuring a MyODBC DSN on Unix".

To **uninstall** the driver, become root and execute an **rpm** command:

```
shell> su root
shell> rpm -e MyODBC
```

25.1.5.2. Installing MyODBC from a Binary Tarball Distribution

To install the driver from a tarball distribution (`.tar.gz` file), download the latest version of the driver for your operating system and follow these steps:

```
shell> su root
shell> gunzip MyODBC-3.51.01-i686-pc-linux.tar.gz
shell> tar xvf MyODBC-3.51.01-i686-pc-linux.tar
shell> cd MyODBC-3.51.01-i686-pc-linux
```

Read the installation instructions in the `INSTALL-BINARY` file and execute these commands.

```
shell> cp libmyodbc* /usr/local/lib
shell> cp odbc.ini /usr/local/etc
shell> export ODBCINI=/usr/local/etc/odbc.ini
```

Then proceed on to Section 25.1.9.3, “Configuring a MyODBC DSN on Unix” to configure the DSN for MyODBC. For more information, refer to the `INSTALL-BINARY` file that comes with your distribution.

25.1.6. Installing MyODBC from a Source Distribution on Windows

25.1.6.1. Requirements

- MDAC, Microsoft Data Access SDK from <http://www.microsoft.com/data/>.
- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because MyODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.

25.1.6.2. Building MyODBC 3.51

MyODBC 3.51 source distributions include `Makefiles` that uses `nmake`. In the distribution, you can find `Makefile` for building the release version and `Makefile_debug` for building debugging versions of the driver libraries and DLLs.

To build the driver, use this procedure:

1. Download and extract the sources to a folder, then change location into that folder. The following command assumes the folder is named `myodbc3-src`:

```
C:\> cd myodbc3-src
```

2. Edit `Makefile` to specify the correct path for the MySQL client libraries and header files. Then use the following commands to build and install the release version:

```
C:\> nmake -f Makefile
C:\> nmake -f Makefile install
```

nmake -f Makefile builds the release version of the driver and places the binaries in subdirectory called `Release`.

nmake -f Makefile install installs (copies) the driver DLLs and libraries (`myodbc3.dll`, `myodbc3.lib`) to your system directory.

3. To build the debug version, use `Makefile_Debug` rather than `Makefile`, as shown below:

```
C:\> nmake -f Makefile_debug
C:\> nmake -f Makefile_debug install
```

4. You can clean and rebuild the driver by using:

```
C:\> nmake -f Makefile clean
C:\> nmake -f Makefile install
```

Note:

- Make sure to specify the correct MySQL client libraries and header files path in the Makefiles (set the `MYSQL_LIB_PATH` and `MYSQL_INCLUDE_PATH` variables). The default header file path is assumed to be `C:\mysql\include`. The default library path is assumed to be `C:\mysql\lib\opt` for release DLLs and `C:\mysql\lib\debug` for debug versions.
- For the complete usage of **nmake**, visit http://msdn.microsoft.com/library/default.asp?url=/library/en-us/dv_vcce4/html/evgrfRunningNMAKE.asp.
- If you are using the BitKeeper tree for compiling, All Windows-specific Makefiles are named as `Win_Makefile*`.

25.1.6.3. Testing

After the driver libraries are copied/installed to the system directory, you can test whether the libraries are properly built by using the samples provided in the `samples` subdirectory:

```
C:\> cd samples
C:\> nmake -f Makefile all
```

25.1.6.4. Building MyODBC 2.50

The MyODBC 2.50 source distribution includes VC workspace files. You can build the driver using these files (`.dsp` and `.dsw`) directly by loading them from Microsoft Visual Studio 6.0 or higher.

25.1.7. Installing MyODBC from a Source Distribution on Unix

25.1.7.1. Requirements

- MySQL client libraries and include files from MySQL 4.0.0 or higher. (Preferably MySQL 4.0.16 or higher). This is required because MyODBC uses new calls and structures that exist only starting from this version of the library. To get the client libraries and include files, visit <http://dev.mysql.com/downloads/>.
- The MySQL library must be configured with the `--enable-thread-safe-client` option. `libmysqlclient` installed as a shared library.
- One of the following Unix ODBC driver managers must be installed:
 - `iodbc` 3.0 or later (<http://www.iodbc.org>)
 - `unixodbc` Alpha 3 or later (<http://www.unixodbc.org>)
- If using a **character set** that isn't compiled into the MySQL client library (the defaults are: `latin1` `big5` `czech` `euc_kr` `gb2312` `gbk` `sjis` `tis620` `ujis`) then you need to install the mysql character definitions from the `charsets` directory into `SHAREDIR` (by default, `/usr/local/mysql/share/mysql/charsets`). These should be in place if you have installed the MySQL server on the same machine.

Once you have all the required files, unpack the source files to a separate directory and follow the instructions as given below:

25.1.7.2. Typical configure Options

The **configure** script gives you a great deal of control over how you configure your MyODBC build. Typically you do this using options on the **configure** command line. You can also affect **configure** using certain environment variables. For a list of options and environment variables supported by **configure**, run this command:

```
shell> ./configure --help
```

Some of the more commonly used **configure** options are described here:

1. To compile MyODBC, you need to supply the MySQL client include and library files path using the `--with-mysql-path=DIR` option, where *DIR* is the directory where the MySQL is installed.

MySQL compile options can be determined by running `DIR/bin/mysql_config`.

2. Supply the standard header and library files path for your ODBC Driver Manager(`iodbc` or `unixodbc`).

- If you are using `iodbc` and `iodbc` is not installed in its default location (`/usr/local`), you might have to use the `--with-iodbc=DIR` option, where *DIR* is the directory where `iodbc` is installed.

If the `iodbc` headers do not reside in `DIR/include`, you can use the `--with-iodbc-includes=INCDIR` option to specify their location.

The applies to libraries. If they are not in `DIR/lib`, you can use the `--with-iodbc-libs=LIBDIR` option.

- If you are using `unixODBC`, use the `--with-unixODBC=DIR` option (case sensitive) to make **configure** look for `unixODBC` instead of `iodbc` by default, *DIR* is the directory where `unixODBC` is installed.

If the `unixODBC` headers and libraries aren't located in `DIR/include` and `DIR/lib`, use the `--with-unixODBC-includes=INCDIR` and `--with-unixODBC-libs=LIBDIR` options.

3. You might want to specify an installation prefix other than `/usr/local`. For example, to install the MyODBC drivers in `/usr/local/odbc/lib`, use the `--prefix=/usr/local/odbc` option.

The final configuration command looks something like this:

```
shell> ./configure --prefix=/usr/local \  
                --with-iodbc=/usr/local \  
                --with-mysql-path=/usr/local/mysql
```

25.1.7.3. Thread-Safe Client

In order to link the driver with MySQL thread safe client libraries `libmysqlclient_r.so` or `libmysqlclient_r.a`, you must specify the following **configure** option:

```
--enable-thread-safe
```

and can be disabled(default) using

```
--disable-thread-safe
```

This option enables the building of driver thread-safe library `libmyodbc3_r.so` from by linking

with mysql thread-safe client library `libmysqlclient_r.so` (The extensions are OS dependent).

In case while configuring with thread-safe option, and gotten into a configure error; then look at the `config.log` and see if it is due to the lack of thread-libraries in the system; and supply one with LIBS options i.e.

```
LIBS="-lpthread" ./configure ..
```

25.1.7.4. Shared or Static Options

You can enable or disable the shared and static versions using these options:

```
--enable-shared[=yes/no]
--disable-shared
--enable-static[=yes/no]
--disable-static
```

25.1.7.5. Enabling Debugging Information

By default, all the binary distributions are built as non-debugging versions (configured with `--without-debug`).

To enable debugging information, build the driver from source distribution and use the `--with-debug` when you run **configure**.

25.1.7.6. Enabling the Documentation

This option is available only for BK clone trees; not for normal source distributions.

By default, the driver is built with (`--without-docs`); And in case if you want the documentation to be taken care in the normal build, then configure with:

```
--with-docs
```

25.1.7.7. Building and Compilation

To build the driver libraries, you have to just execute **make**, which takes care of everything.

```
shell> make
```

If any errors occur, correct them and continue the build process. If you aren't able to build, then send a detailed email to `<myodbc@lists.mysql.com>` for further assistance.

25.1.7.8. Building Shared Libraries

On most platforms, MySQL doesn't build or support `.so` (shared) client libraries by default, because building with shared libraries has caused us problems in the past.

In cases like this, you have to download the MySQL distribution and configure it with these options:

```
--without-server --enable-shared
```

To build shared driver libraries, you must specify the `--enable-shared` option for **configure**. By default, **configure** does not enable this option.

If you have configured with the `--disable-shared` option, you can build the `.so` file from the static libraries using the following commands:

```
shell> cd MyODBC-3.51.01
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
      $CC -bundle -flat_namespace -undefined error \
          -o .libs/libmyodbc3-3.51.01.so \
          catalog.o connect.o cursor.o dll.o error.o execute.o \
          handle.o info.o misc.o myodbc3.o options.o prepare.o \
          results.o transact.o utility.o \
          -L/usr/local/mysql/lib/mysql/ \
          -L/usr/local/iodbc/lib/ \
          -lz -lc -lmysqlclient -liodbcinst
```

Make sure to change `-liodbcinst` to `-lodbcinst` if you are using unixODBC instead of iODBC, and configure the library paths accordingly.

This builds and places the `libmyodbc3-3.51.01.so` file in the `.libs` directory. Copy this file to MyODBC library directory (`/usr/local/lib` (or the `lib` directory under the installation directory that you supplied with the `--prefix`).

```
shell> cd .libs
shell> cp libmyodbc3-3.51.01.so /usr/local/lib
shell> cd /usr/local/lib
shell> ln -s libmyodbc3-3.51.01.so libmyodbc3.so
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
      $CC -bundle -flat_namespace -undefined error \
          -o .libs/libmyodbc3_r-3.51.01.so \
          catalog.o connect.o cursor.o dll.o error.o execute.o \
          handle.o info.o misc.o myodbc3.o options.o prepare.o \
          results.o transact.o utility.o \
          -L/usr/local/mysql/lib/mysql/ \
          -L/usr/local/iodbc/lib/ \
          -lz -lc -lmysqlclient_r -liodbcinst
```

25.1.7.9. Installing Driver Libraries

To install the driver libraries, execute the following command:

```
shell> make install
```

That command installs one of the following sets of libraries:

For MyODBC 3.51:

- `libmyodbc3.so`
- `libmyodbc3-3.51.01.so`, where 3.51.01 is the version of the driver
- `libmyodbc3.a`

For thread-safe MyODBC 3.51:

- `libmyodbc3_r.so`
- `libmyodbc3-3_r.51.01.so`

- `libmyodbc3_r.a`

For MyODBC 2.5.0:

- `libmyodbc.so`
- `libmyodbc-2.50.39.so`, where 2.50.39 is the version of the driver
- `libmyodbc.a`

For more information on build process, refer to the `INSTALL` file that comes with the source distribution. Note that if you are trying to use the `make` from Sun, you may end up with errors. On the other hand, GNU `gmake` should work fine on all platforms.

25.1.7.10. Testing MyODBC on Unix

To run the basic samples provided in the distribution with the libraries that you built, just execute:

```
shell> make test
```

Make sure the DSN 'myodbc3' is configured first in `odbc.ini` and environment variable `ODBCINI` is pointing to the right `odbc.ini` file; and MySQL server is running. You can find a sample `odbc.ini` with the driver distribution.

You can even modify the `samples/run-samples` script to pass the desired DSN, UID, and PASSWORD values as the command line arguments to each sample.

25.1.7.11. Mac OS X Notes

To build the driver on Mac OS X (Darwin), make use of the following **configure** example:

```
shell> ./configure --prefix=/usr/local
                --with-unixODBC=/usr/local
                --with-mysql-path=/usr/local/mysql
                --disable-shared
                --enable-gui=no
                --host=powerpc-apple
```

The command assumes that the `unixODBC` and `MySQL` are installed in the default locations. If not, configure accordingly.

On Mac OS X, `--enable-shared` builds `.dylib` files by default. You can build `.so` files like this:

```
shell> make
shell> cd driver
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error
    -o .libs/libmyodbc3-3.51.01.so *.o
    -L/usr/local/mysql/lib/
    -L/usr/local/iodbc/lib
    -liodbcinst -lmysqlclient -lz -lc
```

To build the thread-safe driver library:

```
shell> CC=/usr/bin/gcc \
    $CC -bundle -flat_namespace -undefined error
    -o .libs/libmyodbc3-3.51.01.so *.o
    -L/usr/local/mysql/lib/
```

```
-L/usr/local/iodbc/lib  
-liodbcinst -lmysqlclienti_r -lz -lc -lpthread
```

Make sure to change the `-liodbcinst` to `-lodbcinst` in case of using unixODBC instead of iODBC and configure the libraries path accordingly.

In Apple's version of GCC, both `cc` and `gcc` are actually symbolic links to `gcc3`.

Copy this library to the `$prefix/lib` directory and symlink to `libmyodbc3.so`.

You can cross-check the output shared-library properties using this command:

```
shell> otool -LD .libs/libmyodbc3-3.51.01.so
```

25.1.7.12. HP-UX Notes

To build the driver on HP-UX 10.x or 11.x, make use of the following **configure** example:

If using `cc`:

```
shell> CC="cc" \  
CFLAGS="+z" \  
LDFLAGS="-Wl,+b:-Wl,+s" \  
./configure --prefix=/usr/local  
--with-unixodbc=/usr/local  
--with-mysql-path=/usr/local/mysql/lib/mysql  
--enable-shared  
--enable-thread-safe
```

If using `gcc`:

```
shell> CC="gcc" \  
LDFLAGS="-Wl,+b:-Wl,+s" \  
./configure --prefix=/usr/local  
--with-unixodbc=/usr/local  
--with-mysql-path=/usr/local/mysql  
--enable-shared  
--enable-thread-safe
```

Once the driver is built, cross-check its attributes using `chatr .libs/libmyodbc3.sl` to see whether or not you need to have the MySQL client libraries path using the `SHLIB_PATH` environment variable. For static versions, ignore all shared-library options and run **configure** with the `-disable-shared` option.

25.1.7.13. AIX Notes:

To build the driver on AIX, make use of the following **configure** example:

```
shell> ./configure --prefix=/usr/local  
--with-unixodbc=/usr/local  
--with-mysql-path=/usr/local/mysql  
--disable-shared  
--enable-thread-safe
```

NOTE: For more information about how to build and set up the static and shared libraries across the different platforms refer to 'Using static and shared libraries across platforms [<http://www.fortran-2000.com/ArnaudRecipes/sharedlib.html>]'

25.1.8. Installing MyODBC from the BitKeeper Develop-

ment Source Tree

Note: You should read this section only if you are interested in helping us test our new code.

To obtain our most recent development source tree, use these instructions:

1. Download BitKeeper from <http://www.bitmover.com/cgi-bin/download.cgi>. You need BitKeeper 3.0 or newer to access our repository.
2. Follow the instructions to install it.
3. After BitKeeper is installed, first go to the directory you want to work from, and then use this command if you want to clone the MyODBC 3.51 branch:

```
shell> bk clone bk://mysql.bkbits.net/myodbc3 myodbc-3.51
```

In the preceding example, the source tree is set up in the `myodbc-3.51/` or by default `myodbc3/` subdirectory of your current directory. If you are behind the firewall and can only initiate HTTP connections, you can also use BitKeeper via HTTP. If you are required to use a proxy server, simply set the environment variable `http_proxy` to point to your proxy:

```
shell> export http_proxy="http://your.proxy.server:8080/"
```

Replace the `bk://` with `http://` when doing a clone. Example:

```
shell> bk clone http://mysql.bkbits.net/myodbc3 myodbc-3.51
```

The initial download of the source tree may take a while, depending on the speed of your connection; be patient.

4. You need GNU `autoconf 2.52` (or newer), `automake 1.4`, `libtool 1.4`, and `m4` to run the next set of commands.

```
shell> cd myodbc-3.51
shell> bk -r edit
shell> aclocal; autoheader; autoconf; automake;
shell> ./configure # Add your favorite options here
shell> make
```

For more information on how to build, refer to `INSTALL` file located in the same directory. On Windows, make use of Windows Makefiles `WIN-Makefile` and `WIN-Makefile_debug` in building the driver, for more information, see Section 25.1.6, “Installing MyODBC from a Source Distribution on Windows”.

5. When the build is done, run **make install** to install the MyODBC 3.51 driver on your system.
6. If you have gotten to the **make** stage and the distribution does not compile, please report it to `<myodbc@lists.mysql.com>`.
7. After the initial **bk clone** operation to get the source tree, you should run **bk pull** periodically to get the updates.
8. You can examine the change history for the tree with all the diffs by using **bk sccstool**. If you see some funny diffs or code that you have a question about, do not hesitate to send e-mail to `<myodbc@lists.mysql.com>`.

Also, if you think you have a better idea on how to do something, send an e-mail to the same address with a patch. **bk diffs** produces a patch for you after you have made changes to the source. If you do not have the time to code your idea, just send a description.

9. BitKeeper has a nice help utility that you can access via **bk helptool**.

You can also browse changesets, comments and source code online by browsing to <http://mysql.bkbits.net:8080/myodbc3>.

25.1.9. MyODBC Configuration

This section describes how to configure MyODBC, including DSN creation and the different arguments that the driver takes as an input arguments in the connection string. It also describes how to create an ODBC trace file.

25.1.9.1. What is a Data Source Name?

A "data source" is a place where data comes from. The data source must have a persistent identifier, the Data Source Name. Using the Data Source Name, MySQL can access initialization information. With the initialization information, MySQL knows where to access the database and what settings to use when the access starts.

In effect, the data source is the *path* to the data. In different contexts this might mean different things, but typically it identifies a running MySQL server (for example via a network address or service name), plus the default database for that server at connection time, plus necessary connection information such as the port. The MySQL drivers (and, on Windows systems, the ODBC Driver Manager) use the data source for connecting. An administrative utility called the Microsoft ODBC Data Source Administrator may be useful for this purpose.

There are two places where the initialization information might be: in the Windows registry (on a Windows system), or in a DSN file (on any system).

If the information is in the Windows registry, it is called a "Machine data source". It might be a "User data source", in which case only one user can see it. Or it might be a "System data source" in which case it is accessible to all users on the computer, or indeed to all users connected to the computer, if the users are connected by Microsoft Windows NT services. When you run the ODBC Data Administration program, you have a choice whether to use "User" or "System" -- there are separate tabs.

If the information is in a DSN file, it is called a "File data source". This is a text file. Its advantages are: (a) it is an option for any kind of computer, not just a computer with a Windows operating system; (b) its contents can be transmitted or copied relatively easily.

25.1.9.2. Configuring a MyODBC DSN on Windows

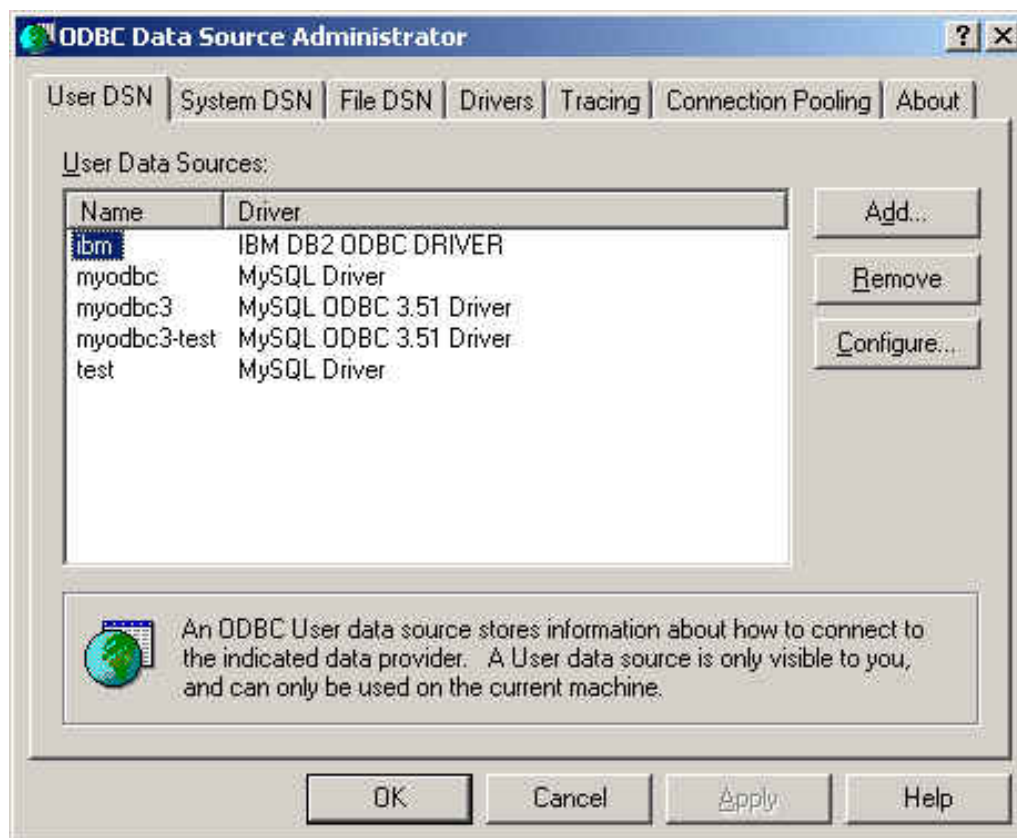

To add and configure a new MyODBC data source on Windows, use the ODBC Data Source Administrator. The ODBC Administrator updates your data source connection information. As you add data sources, the ODBC Administrator updates the registry information for you.

To open the ODBC Administrator from the Control Panel:

1. Click **Start**, point to **Settings**, and then click **Control Panel**.
2. On computers running Microsoft Windows 2000 or newer, double-click **Administrative Tools**, and then double-click **Data Sources (ODBC)**. On computers running older versions of Windows, double-click **32-bit ODBC** or **ODBC**.

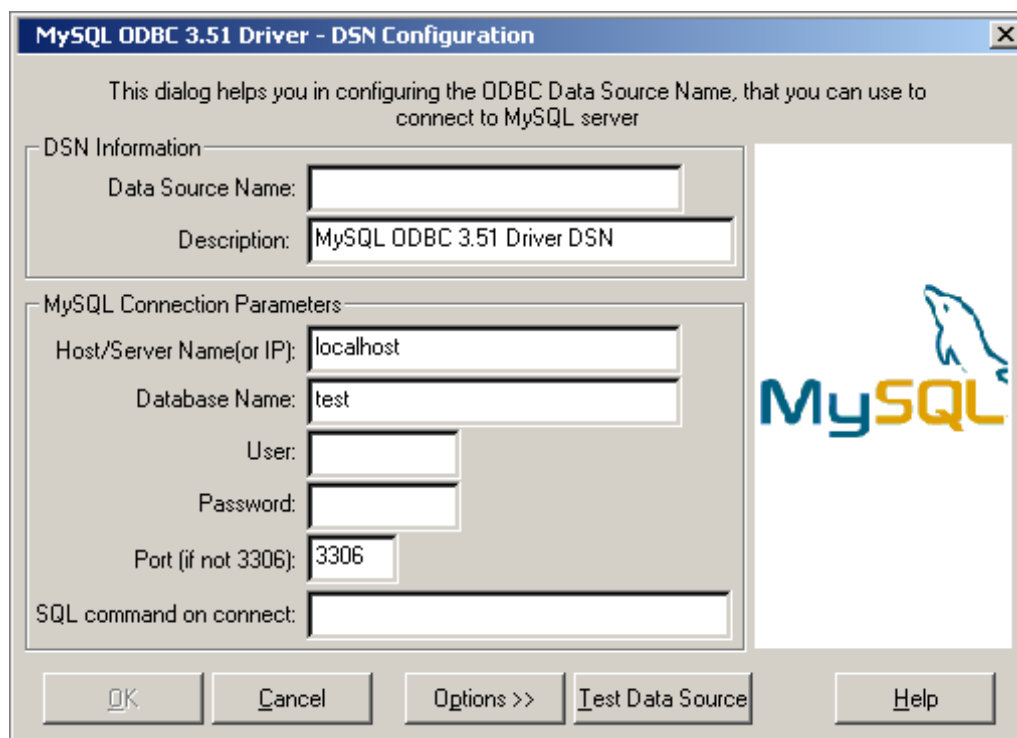

The ODBC Data Source Administrator dialog box appears, as shown here:

Click Help for detailed information about each tab of the ODBC Data Source Administrator dialog box.

To add a data source on Windows:

1. Open the ODBC Data Source Administrator.
2. In the ODBC Data Source Administrator dialog box, click Add. The Create New Data Source dialog box appears.
3. Select MySQL ODBC 3.51 Driver, and then click Finish. The MySQL ODBC 3.51 Driver - DSN Configuration dialog box appears, as shown here:

4. In the `Data Source Name` box, enter the name of the data source you want to access. It can be any valid name that you choose.
5. In the `Description` box, enter the description needed for the DSN.
6. For `Host or Server Name (or IP)` box, enter the name of the MySQL server host that you want to access. By default, it is `localhost`.
7. In the `Database Name` box, enter the name of the MySQL database that you want to use as the default database.
8. In the `User` box, enter your MySQL username (your database user ID).
9. In the `Password` box, enter your password.
10. In the `Port` box, enter the port number if it is not the default (3306).
11. In the `SQL Command` box, you can enter an optional SQL statement that you want to issue automatically after the connection has been established.

The final dialog looks like this:

Click OK to add this data source.

Note: Upon clicking OK, the Data Sources dialog box appears, and the ODBC Administrator updates the registry information. The username and connect string that you entered become the default connection values for this data source when you connect to it.

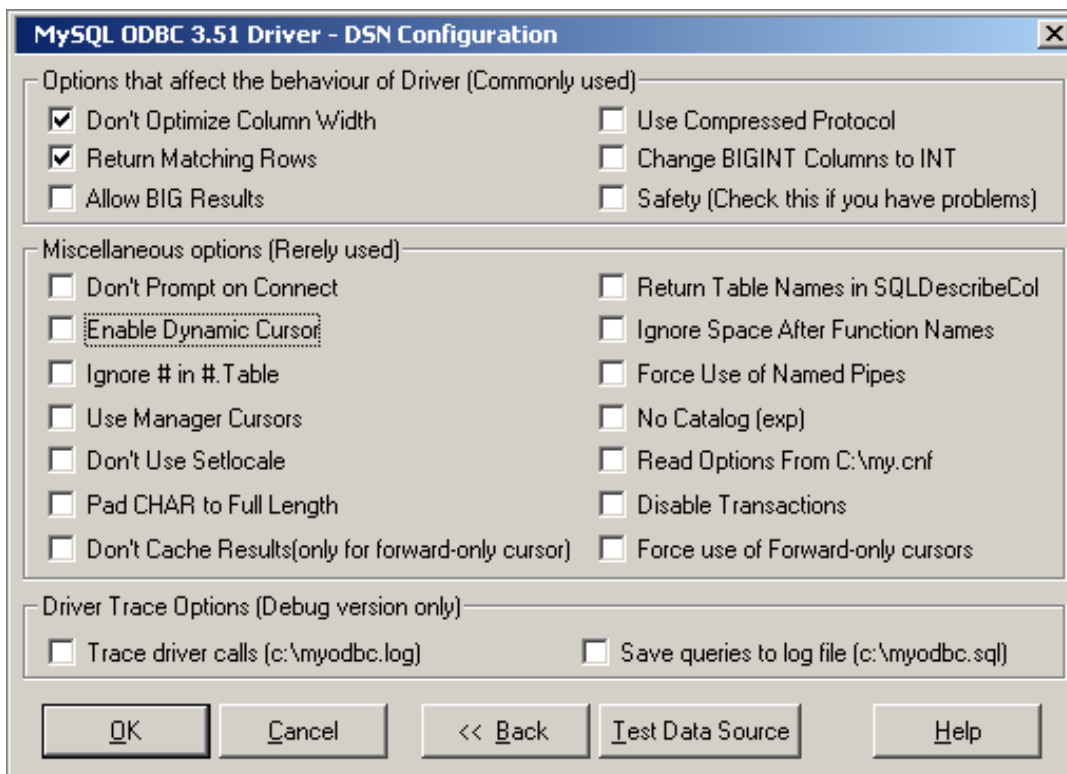

You can also test whether your settings are suitable for connecting to the server using the button Test Data Source. This feature is available only for the MyODBC 3.51 driver. A successful test results in the following window:

A failed test results in an error:

The DSN configuration dialog also has an Options button. If you select it, the following options dialog appears displaying that control driver behavior. Refer to Section 25.1.9.4, “Connection Parameters” for information about the meaning of these options.

Note: The options listed under Driver Trace Options are disabled (grayed out) unless you are using the debugging version of the driver DLL.

To modify a data source on Windows:

1. Open the ODBC Data Source Administrator. Click the appropriate DSN tab.
2. Select the MySQL data source that you want to modify and then click Configure. The MySQL ODBC 3.51 Driver - DSN Configuration dialog box appears.
3. Modify the applicable data source fields, and then click OK.

When you have finished modifying the information in this dialog box, the ODBC Administrator updates the registry information.

25.1.9.3. Configuring a MyODBC DSN on Unix

On Unix, you configure DSN entries directly in the `odbc.ini` file. Here is a typical `odbc.ini` file that configures `myodbc` and `myodbc3` as the DSN names for MyODBC 2.50 and MyODBC 3.51, respectively:

```

;
; odbc.ini configuration for MyODBC and MyODBC 3.51 drivers
;

[ODBC Data Sources]
myodbc      = MyODBC 2.50 Driver DSN
myodbc3     = MyODBC 3.51 Driver DSN

[myodbc]
Driver      = /usr/local/lib/libmyodbc.so
Description = MyODBC 2.50 Driver DSN
SERVER      = localhost
PORT        =

```

```

USER          = root
Password     =
Database     = test
OPTION       = 3
SOCKET       =

[myodbc3]
Driver       = /usr/local/lib/libmyodbc3.so
Description  = MyODBC 3.51 Driver DSN
SERVER      = localhost
PORT        =
USER        = root
Password    =
Database    = test
OPTION     = 3
SOCKET     =

[Default]
Driver       = /usr/local/lib/libmyodbc3.so
Description  = MyODBC 3.51 Driver DSN
SERVER      = localhost
PORT        =
USER        = root
Password    =
Database    = test
OPTION     = 3
SOCKET     =
    
```

Refer to the Section 25.1.9.4, “Connection Parameters”, for the list of connection parameters that can be supplied.

Note: If you are using unixODBC, you can use the following tools in order to set up the DSN:

- ODBCConfig GUI tool(HOWTO: ODBCConfig [<http://www.unixodbc.org/config.html>])
- odbcinst

In some cases when using unixODBC, you might get this error:

```
Data source name not found and no default driver specified
```

If this happens, make sure the ODBCINI and ODBCSYSINI environment variables are pointing to the right `odbc.ini` file. For example, if your `odbc.ini` file is located in `/usr/local/etc`, set the environment variables like this:

```
export ODBCINI=/usr/local/etc/odbc.ini
export ODBCSYSINI=/usr/local/etc
```

25.1.9.4. Connection Parameters

You can specify the following parameters for MyODBC in the [Data Source Name] section of an ODBC.INI file or through the `InConnectionString` argument in the `SQLDriverConnect()` call.

Parameter	Default Value	Comment
user	ODBC (on Windows)	The username used to connect to MySQL.
server	localhost	The hostname of the MySQL server.
database		The default database.

option	0	Options that specify how MyODBC should work. See below.
port	3306	The TCP/IP port to use if server is not localhost.
stmt		A statement to execute when connecting to MySQL.
password		The password for the user account on server.
socket		The Unix socket file or Windows named pipe to connect to if server is localhost.

The `option` argument is used to tell MyODBC that the client isn't 100% ODBC compliant. On Windows, you normally select options by toggling the checkboxes in the connection screen, but you can also select them in the `option` argument. The following options are listed in the order in which they appear in the MyODBC connect screen:

Value	Description
1	The client can't handle that MyODBC returns the real width of a column.
2	The client can't handle that MySQL returns the true value of affected rows. If this flag is set, MySQL returns "found rows" instead. You must have MySQL 3.21.14 or newer to get this to work.
4	Make a debug log in <code>c:\myodbc.log</code> . This is the same as putting <code>MYSQL_DEBUG=d:t:0,c::\myodbc.log</code> in <code>AUTOEXEC.BAT</code> . (On Unix, the file is <code>/tmp/myodbc.log</code> .)
8	Don't set any packet limit for results and parameters.
16	Don't prompt for questions even if driver would like to prompt.
32	Enable or disable the dynamic cursor support. (Not allowed in MyODBC 2.50.)
64	Ignore use of database name in <code>db_name.tbl_name.col_name</code> .
128	Force use of ODBC manager cursors (experimental).
256	Disable the use of extended fetch (experimental).
512	Pad CHAR columns to full column length.
1024	<code>SQLDescribeCol()</code> returns fully qualified column names.
2048	Use the compressed client/server protocol.
4096	Tell server to ignore space after function name and before '(' (needed by PowerBuilder). This makes all function names keywords.
8192	Connect with named pipes to a mysqld server running on NT.
16384	Change LONGLONG columns to INT columns (some applications can't handle LONGLONG).
32768	Return 'user' as <code>Table_qualifier</code> and <code>Table_owner</code> from <code>SQLTables</code> (experimental).
65536	Read parameters from the <code>[client]</code> and <code>[odbc]</code> groups from <code>my.cnf</code> .
131072	Add some extra safety checks (should not be needed but...).
262144	Disable transactions.
524288	Enable query logging to <code>c:\myodbc.sql(/tmp/myodbc.sql)</code> file. (Enabled only in debug mode.)
1048576	Do not cache the results locally in the driver, instead read from server (<code>mysql_use_result()</code>). This works only for forward-only cursors. This option is very important in dealing with large tables when you don't want the driver to cache the entire result set.
2097152	Force the use of Forward-only cursor type. In case of applications setting the default static/dynamic cursor type, and one wants the driver to use non-cache result sets, then this option ensures the forward-only cursor behavior.

To select multiple options, add together their values. For example, setting `option` to 12 (4+8) gives you debugging without packet limits.

The default `myodbc3.dll` is compiled for optimal performance. If you want to debug MyODBC 3.51 (for example, to enable tracing), you should instead use `myodbc3d.dll`. To install this file, copy `myodbc3d.dll` over the installed `myodbc3.dll` file. Make sure to revert back to the release version of the driver DLL once you are done with the debugging because the debug version may cause performance issues.

For MyODBC 2.50, `myodbc.dll` and `myodbc.d.dll` are used instead.

The following table shows some recommended `option` values for various configurations:

Configuration	Option Value
Microsoft Access	3
Microsoft Visual Basic	3
Large tables with too many rows	2049
Driver trace generation (Debug mode)	4
Query log generation (Debug mode)	524288
Generate driver trace as well as query log (Debug mode)	524292
Large tables with no-cache results	3145731

25.1.9.5. Connecting Without a Predefined DSN

Yes. You can connect to the MySQL server using `SQLDriverConnect`, by specifying the `DRIVER` name field. Here are the connection strings for MyODBC using DSN-Less connection:

For MyODBC 2.50:

```
ConnectionString = "DRIVER={MySQL};\
SERVER=localhost;\
DATABASE=test;\
USER=venu;\
PASSWORD=venu;\
OPTION=3;"
```

For MyODBC 3.51:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};\
SERVER=localhost;\
DATABASE=test;\
USER=venu;\
PASSWORD=venu;\
OPTION=3;"
```

If your programming language converts backslash followed by whitespace to a space, it is preferable to specify the connection string as a single long string, or to use a concatenation of multiple strings that does not add spaces in between. For example:

```
ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"
"SERVER=localhost;"
"DATABASE=test;"
"USER=venu;"
"PASSWORD=venu;"
"OPTION=3;"
```

Refer to the Section 25.1.9.4, "Connection Parameters", for the list of connection parameters that can be supplied.

25.1.9.6. Establishing a Remote Connection to System A from System B

If you want to connect to system A from system B with a username and password of `myuser` and `mypassword`, here is a simple procedure.

On system A, follow these steps:

1. Start the MySQL server.
2. Use `GRANT` to set up an account with a username of `myuser` that can connect from system B using a password of `myuser`:

```
GRANT ALL ON *.* to 'myuser'@'B' IDENTIFIED BY 'mypassword';
```

3. The `GRANT` statement grants all privileges to user `myuser` for connecting from system B using the password `mypassword`. To execute this statement, you should be either `root` on system A (or another user who has appropriate privileges). For more information about MySQL privileges, refer to Section 5.7, “MySQL User Account Management”.

On system B, follow these steps:

1. Configure a MyODBC DSN using the following connection parameters:

```
DSN           = remote_test
SERVER or HOST = A (or IP address of system A)
DATABASE      = test (The default database or an appropriate one)
USER         = myuser
PASSWORD     = mypassword
```

To set up a DSN-less connection, refer to Section 25.1.9.5, “Connecting Without a Predefined DSN”.

2. Check whether you are able to access system A from system B by using ping or other means. If you are not able to reach system A, check your network or Internet connections or contact your system administrator.
3. Try to connect using `DSN=remote_test`. If it fails, trace the MyODBC log, and take the further steps based on the error message from the log. If you need further assistance, send a detailed mail message to `<myodbc@lists.mysql.com>`.

You can also find a simple HOWTO at <http://www.phphelp.com/tutorial/using-myodbc-to-connect-to-a-remote-database.html>.

25.1.9.7. Getting an ODBC Trace File

If you encounter difficulties or problems with MyODBC, you should start by making a log file from the ODBC Manager (the log you get when requesting logs from ODBC ADMIN) and MyODBC.

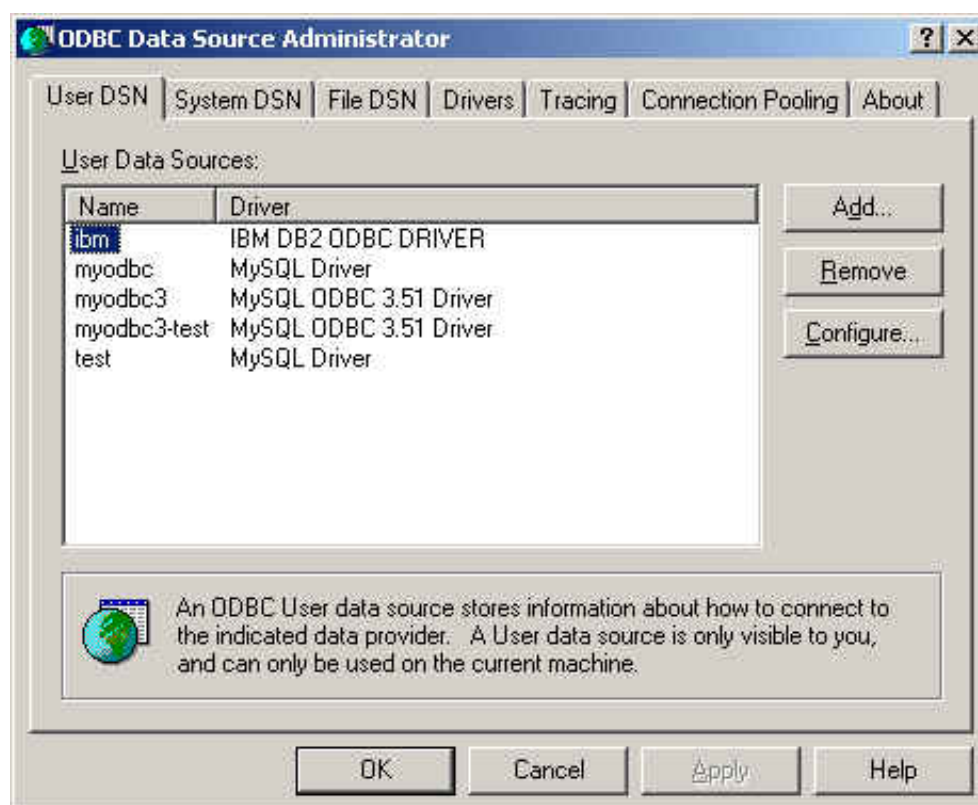

To get an ODBC trace through Driver Manager, do the following:

- Open ODBC Data source administrator:
 1. Click `Start`, point to `Settings`, and then click `Control Panel`.
 2. On computers running Microsoft Windows 2000, XP, or 2003, double-click `Administrative Tools`, and then double-click `Data Sources (ODBC)`, as shown below.

On computers running an earlier version of Microsoft Windows, double-click 32-bit ODBC or ODBC in the Control Panel.

- The ODBC Data Source Administrator dialog box appears, as shown below:

- Click Help for detailed information about each tab of the ODBC Data Source Administrator dialog box.
- Enable the trace option. The procedure for this differs for Windows and Unix.

To enable the trace option on Windows:

- The Tracing tab of the ODBC Data Source Administrator dialog box enables you to configure the way ODBC function calls are traced.
- When you activate tracing from the Tracing tab, the Driver Manager logs all ODBC function calls for all subsequently run applications.
- ODBC function calls from applications running before tracing is activated are not logged. ODBC function calls are recorded in a log file you specify.
- Tracing ceases only after you click Stop Tracing Now. Remember that while tracing is on, the log file continues to increase in size and that tracing affects the performance of all your ODBC applications.

To enable the trace option on Unix:

1. On Unix, you need to explicitly set the Trace option in the ODBC.INI file.

Set the tracing ON or OFF by using TraceFile and Trace parameters in odbc.ini as shown below:

```
TraceFile = /tmp/odbc.trace
Trace     = 1
```

TraceFile specifies the name and full path of the trace file and Trace is set to ON or OFF. You can also use 1 or YES for ON and 0 or NO for OFF. If you are using **ODBCConfig** from unixODBC, then follow the instructions for tracing unixODBC calls at HOWTO-ODBCConfig [<http://www.unixodbc.org/config.html>].

To generate a MyODBC log, do the following:

1. Ensure that you are using the driver debug DLL (that is, myodbc3d.dll and not myodbc3.dll for MyODBC 3.51, and myodbcd.dll for MyODBC 2.50).

The easiest way to do this is to get myodbc3d.dll (or myodbcd.dll) from the MyODBC 3.51 distribution and copy it over the myodbc3.dll (or myodbc.dll), which is probably in your C:\\windows\\system32 or C:\\winnt\\system32 directory. Note that you probably want to restore the old myodbc.dll file when you have finished testing, as this is a lot faster than myodbc3d.dll (or myodbcd.dll), so do keep a backup copy of original DLLs.

2. Enable the Trace MyODBC option flag in the MyODBC connect/configure screen. The log is written to file C:\\myodbc.log. If the trace option is not remembered when you are going back to the above screen, it means that you are not using the myodbcd.dll driver (see above). On Linux or if you are using DSN-Less connection, then you need to supply OPTION=4 in the connection string.

3. Start your application and try to get it to fail. Then check the MyODBC trace file to find out what could be wrong.

If you find out something is wrong, please send a mail message to <myodbc@lists.mysql.com> (or to <support@mysql.com> if you have a support contract from MySQL AB) with a brief description of the problem, with the following additional information:

- MyODBC version
- ODBC Driver Manager type and version
- MySQL server version
- ODBC trace from Driver Manager
- MyODBC log file from MyODBC driver
- Simple reproducible sample

Remember that the more information you can supply to us, the more likely it is that we can fix the problem!

Also, before posting the bug, check the MyODBC mailing list archive at <http://lists.mysql.com/>.

25.1.9.8. Applications Tested with MyODBC

MyODBC has been tested with the following applications:

- MS Access 95, 97, 2000, and 2002
- C++-Builder, Borland Builder 4
- Centura Team Developer (formerly Gupta SQL/Windows)
- ColdFusion (on Solaris and NT with service pack 5), How-to: MySQL and Coldfusion [<http://www.njwtech.net/addons/coldfusion/mysql.html>]. Troubleshooting Data Sources and Database Connectivity for UnixPlatforms [<http://www.macromedia.com/v1/handlers/index.cfm?ID=11328&Method=Full&PageCall=/support/index.cfm>].
- Crystal Reports
- DataJunction
- Delphi
- ERwin
- MS Excel
- iHTML
- FileMaker Pro
- FoxPro
- Notes 4.5/4.6
- MS Visio Enterprise 2000

- Vision
- Visual Objects
- Visual Interdev
- SBSS
- Perl DBD-ODBC
- Paradox
- Powerbuilder
- Powerdesigner 32-bit
- MS Visual C++
- Visual Basic
- ODBC.NET through CSharp(C#), VB and C++
- Data Architect(<http://thekompany.com/products/dataarchitect/>)
- SQLExpress for Xbase++(<http://www.SQLExpress.net>)
- Open Office (<http://www.openoffice.org>) How-to: MySQL + OpenOffice [http://dba.openoffice.org/proposals/MySQL_OOo.html]. How-to: OpenOffice + MyODBC + unixODBC [<http://www.unixodbc.org/doc/OOoMySQL.pdf>].
- Star Office (<http://www.sun.com/software/star/staroffice/6.0/index.html>)
- G2-ODBC bridge (<http://www.gensym.com>)
- Sambar Server (<http://www.sambarserver.info>) How-to: MyODBC + SambarServer + MySQL [<http://www.sambarserver.info/article.php?sid=66>].

If you know of any other applications that work with MyODBC, please send mail to myodbc@lists.mysql.com about them.

25.1.9.9. Programs Known to Work With MyODBC

Most programs should work with MyODBC, but for each of those listed here, we have tested it ourselves or received confirmation from some user that it works. Many of the descriptions provide workarounds for problems that you might encounter.

- **Program**

- **Comment**

- Access

To make Access work:

- If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC (Microsoft Data Access Components) from <http://www.microsoft.com/data/>. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified. Another way to work around this bug is to upgrade to MyODBC 2.50.33 and MySQL 3.23.x, which together provide a work-around for the problem.

You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be

found at <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114>. This fixes some cases where columns are marked as #DELETED# in Access.

Note: If you are using MySQL 3.22, you must to apply the MDAC patch and use MyODBC 2.50.32 or 2.50.34 and up to work around this problem.

- For all versions of Access, you should enable the MyODBC `Return matching rows` option. For Access 2.0, you should additionally enable the `Simulate ODBC 1.0` option.
- You should have a timestamp in all tables that you want to be able to update. For maximum portability, don't use a length specification in the column declaration. That is, use `TIMESTAMP`, not `TIMESTAMP (n)`, $n < 14$.
- You should have a primary key in the table. If not, new or updated rows may show up as #DELETED#.
- Use only `DOUBLE` float fields. Access fails when comparing with single floats. The symptom usually is that new or updated rows may show up as #DELETED# or that you can't find or update rows.
- If you are using MyODBC to link to a table that has a `BIGINT` column, the results are displayed as #DELETED#. The work around solution is:
 - Have one more dummy column with `TIMESTAMP` as the data type.
 - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
 - Delete the table link from Access and re-create it.

Old records still display as #DELETED#, but newly added/updated records are displayed properly.

- If you still get the error `Another user has changed your data` after adding a `TIMESTAMP` column, the following trick may help you:

Don't use a table data sheet view. Instead, create a form with the fields you want, and use that form data sheet view. You should set the `DefaultValue` property for the `TIMESTAMP` column to `NOW()`. It may be a good idea to hide the `TIMESTAMP` column from view so your users are not confused.

- In some cases, Access may generate illegal SQL statements that MySQL can't understand. You can fix this by selecting `"Query|SQLSpecific|Pass-Through"` from the Access menu.
 - On NT, Access reports `BLOB` columns as `OLE OBJECTS`. If you want to have `MEMO` columns instead, you should change `BLOB` columns to `TEXT` with `ALTER TABLE`.
 - Access can't always handle `DATE` columns properly. If you have a problem with these, change the columns to `DATETIME`.
 - If you have in Access a column defined as `BYTE`, Access tries to export this as `TINYINT` instead of `TINYINT UNSIGNED`. This gives you problems if you have values larger than 127 in the column.
- ADO

When you are coding with the ADO API and MyODBC, you need to pay attention to some default properties that aren't supported by the MySQL server. For example, using the `CursorLocation` Property as `adUseServer` returns a result of #1 for the `RecordCount` Property. To have the right value, you need to set this property to `adUseClient`, as shown in the VB code here:

```
Dim myconn As New ADODB.Connection
Dim myrs As New Recordset
Dim mySQL As String
Dim myrows As Long

myconn.Open "DSN=MyODBCsample"
mySQL = "SELECT * from user"
myrs.Source = mySQL
Set myrs.ActiveConnection = myconn
myrs.CursorLocation = adUseClient
myrs.Open
myrows = myrs.RecordCount

myrs.Close
myconn.Close
```

Another workaround is to use a `SELECT COUNT(*)` statement for a similar query to get the correct row count.

- Active server pages (ASP)

You should select the `Return matching rows` option.

- BDE applications

To get these to work, you should select the `Don't optimize column widths` and `Return matching rows` options.

- Borland Builder 4

When you start a query, you can use the `Active` property or the `Open` method. Note that `Active` starts by automatically issuing a `SELECT * FROM ...` query. That may not be a good thing if your tables are large.

- ColdFusion (On Unix)

The following information is taken from the ColdFusion documentation:

Use the following information to configure ColdFusion Server for Linux to use the unixODBC driver with MyODBC for MySQL data sources. Allaire has verified that MyODBC 2.50.26 works with MySQL 3.22.27 and ColdFusion for Linux. (Any newer version should also work.) You can download MyODBC at <http://dev.mysql.com/downloads/connector/odbc/>.

ColdFusion Version 4.5.1 allows you to use the ColdFusion Administrator to add the MySQL data source. However, the driver is not included with ColdFusion Version 4.5.1. Before the MySQL driver appears in the ODBC datasources drop-down list, you must build and copy the MyODBC driver to `/opt/coldfusion/lib/libmyodbc.so`.

The `Contrib` directory contains the program `mysn-xxx.zip` which allows you to build and remove the DSN registry file for the MyODBC driver on Coldfusion applications.

- DataJunction

You have to change it to output `VARCHAR` rather than `ENUM`, as it exports the latter in a manner that causes MySQL problems.

- Excel

Works. A few tips:

- If you have problems with dates, try to select them as strings using the `CONCAT ()` function. For example:

```
SELECT CONCAT(rise_time), CONCAT(set_time)
      FROM sunrise_sunset;
```

Values retrieved as strings this way should be correctly recognized as time values by Excel97.

The purpose of `CONCAT ()` in this example is to fool ODBC into thinking the column is of "string type." Without the `CONCAT ()`, ODBC knows the column is of time type, and Excel does not understand that.

Note that this is a bug in Excel, because it automatically converts a string to a time. This would be great if the source was a text file, but is unfortunate when the source is an ODBC connection that reports exact types for each column.

- Word

To retrieve data from MySQL to Word/Excel documents, you need to use the MyODBC driver and the Add-in Microsoft Query help.

For example, create a database with a table containing two columns of text:

- Insert rows using the **mysql** client command-line tool.
 - Create a DSN file using the ODBC manager, for example, `my` for the database that was just created.
 - Open the Word application.
 - Create a blank new document.
 - In the Database tool bar, press the `Insert Database` button.
 - Press the `Get Data` button.
 - At the right hand of the `Get Data` screen, press the `Ms Query` button.
 - In `Ms Query`, create a new data source using the `my` DSN file.
 - Select the new query.
 - Select the columns that you want.
 - Make a filter if you want.
 - Make a Sort if you want.
 - Select `Return Data to Microsoft Word`.
 - Click `Finish`.
 - Click `Insert Data` and select the records.
 - Click `OK` and you see the rows in your Word document.
- odbcadmin
Test program for ODBC.

- Delphi

You must use BDE Version 3.2 or newer. Select the Don't optimize column width option when connecting to MySQL.

Also, here is some potentially useful Delphi code that sets up both an ODBC entry and a BDE entry for MyODBC. The BDE entry requires a BDE Alias Editor that is free at a Delphi Super Page near you. (Thanks to Bryan Brunton <bryan@flesherfab.com> for this):

```
fReg:= TRegistry.Create;
fReg.OpenKey('\Software\ODBC\ODBC.INI\DocumentsFab', True);
fReg.WriteString('Database', 'Documents');
fReg.WriteString('Description', ' ');
fReg.WriteString('Driver', 'C:\WINNT\System32\myodbc.dll');
fReg.WriteString('Flag', '1');
fReg.WriteString('Password', '');
fReg.WriteString('Port', ' ');
fReg.WriteString('Server', 'xmark');
fReg.WriteString('User', 'winuser');
fReg.OpenKey('\Software\ODBC\ODBC.INI\ODBC Data Sources', True);
fReg.WriteString('DocumentsFab', 'MySQL');
fReg.CloseKey;
fReg.Free;

Memol.Lines.Add('DATABASE NAME=');
Memol.Lines.Add('USER NAME=');
Memol.Lines.Add('ODBC DSN=DocumentsFab');
Memol.Lines.Add('OPEN MODE=READ/WRITE');
Memol.Lines.Add('BATCH COUNT=200');
Memol.Lines.Add('LANGDRIVER=');
Memol.Lines.Add('MAX ROWS=-1');
Memol.Lines.Add('SCHEMA CACHE DIR=');
Memol.Lines.Add('SCHEMA CACHE SIZE=8');
Memol.Lines.Add('SCHEMA CACHE TIME=-1');
Memol.Lines.Add('SQLPASSTHRU MODE=SHARED AUTOCOMMIT');
Memol.Lines.Add('SQLQRYMODE=');
Memol.Lines.Add('ENABLE SCHEMA CACHE=FALSE');
Memol.Lines.Add('ENABLE BCD=FALSE');
Memol.Lines.Add('ROWSET SIZE=20');
Memol.Lines.Add('BLOBS TO CACHE=64');
Memol.Lines.Add('BLOB SIZE=32');

AliasEditor.Add('DocumentsFab', 'MySQL', Memol.Lines);
```

- C++ Builder

Tested with BDE Version 3.0. The only known problem is that when the table schema changes, query fields are not updated. BDE, however, does not seem to recognize primary keys, only the index named PRIMARY, though this has not been a problem.

- Vision

You should select the Return matching rows option.

- Visual Basic

To be able to update a table, you must define a primary key for the table.

Visual Basic with ADO can't handle big integers. This means that some queries like SHOW PROCESSLIST do not work properly. The fix is to use OPTION=16384 in the ODBC connect string or to select the Change BIGINT columns to INT option in the MyODBC connect

screen. You may also want to select the `Return matching rows` option.

- VisualInterDev

If you have a `BIGINT` in your result, you may get the error `[Microsoft][ODBC Driver Manager] Driver does not support this parameter`. Try selecting the `Change BIGINT columns to INT` option in the MyODBC connect screen.

- Visual Objects

You should select the `Don't optimize column widths` option.

- MS Visio Enterprise 2000

We made database model diagram by connecting from MS Visio Enterprise 2000 to MySQL via MyODBC (2.50.37 or greater) and using Visio's reverse engineer function to retrieve information about the DB (Visio shows all the column definitions, primary keys, Indexes and so on). Also we tested by designing new tables in Visio and exported them to MySQL via MyODBC.

25.1.10. MyODBC Connection-Related Issues

This section answers MyODBC connection-related questions.

25.1.10.1. While Configuring a MyODBC DSN, a Could Not Load Translator or Setup Library Error Occurs

For more information, refer to MS KnowledgeBase Article(Q260558) [<http://support.microsoft.com/default.aspx?scid=kb;EN-US;q260558>]. Also, make sure you have the latest valid `ct13d32.dll` in your system directory.

25.1.10.2. While Connecting, an Access denied Error Occurs

Refer to Section 5.6.8, "Causes of Access denied Errors".

25.1.10.3. INFO: About ODBC Connection Pooling

Refer to this document about connection pooling: <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q169470>.

25.1.11. MyODBC and Microsoft Access

This section of the document answers questions related to MyODBC with Microsoft Access.

25.1.11.1. How to Set Up Microsoft Access to Work with MySQL using MyODBC?

The following must be done on your client PC in order to make Microsoft Access work with MyODBC.

1. If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC (Microsoft Data Access Components) from <http://www.microsoft.com/data/>. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified. Another way to work around this bug is to upgrade to MyODBC 2.50.33 and MySQL 3.23.x, which together provide a workaround for the problem.

You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be found at <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114>. This fixes some cases

where columns are marked as #DELETED# in Access.

Note: If you are using MySQL 3.22, you must to apply the MDAC patch and use MyODBC 2.50.32 or 2.50.34 and up to work around this problem.

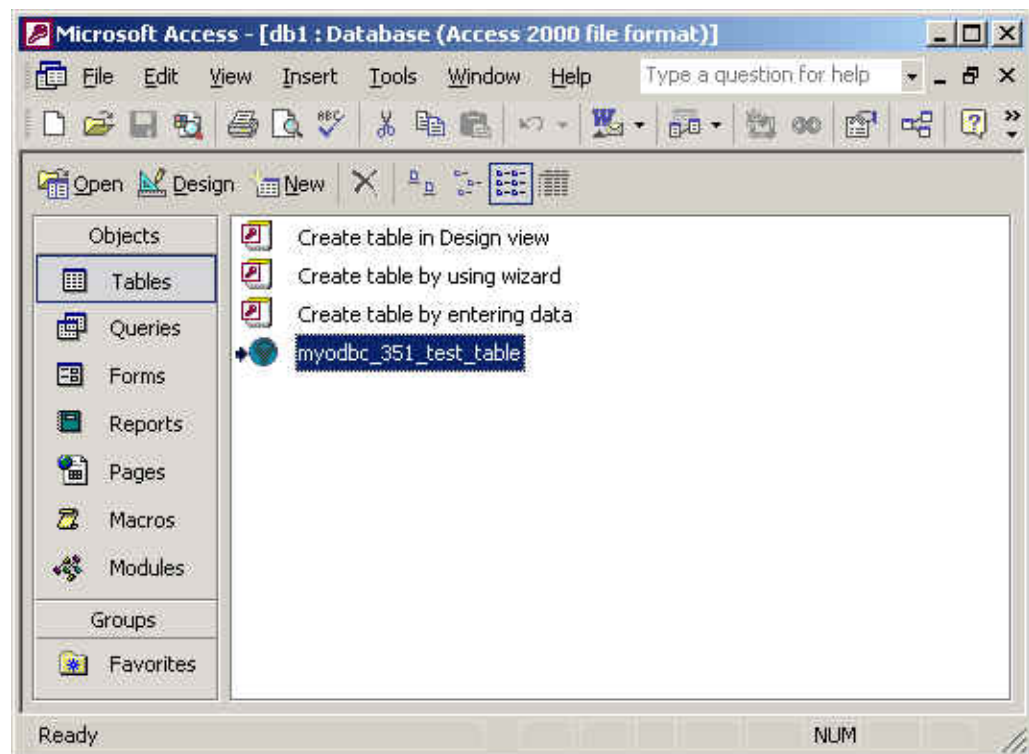

2. Install the latest version of MySQL from <http://dev.mysql.com/downloads/>.
3. Install the latest version of MyODBC 3.51 or 2.50 from <http://dev.mysql.com/downloads/connector/odbc/>.
4. For all Access versions, you should enable the Return matching rows option.
5. Start working with Access as the front-end for MySQL Server through MyODBC.

25.1.11.2. How to Export a Table or Query from Access to MySQL?

You cannot export a table or query to MySQL unless you have installed MyODBC.

To export a table from Access to MySQL, follow these instructions:

1. When you open an Access database or an Access project, a Database window appears. It displays shortcuts for creating new database objects and opening existing objects.

2. Click the name of the table or query you want to export, and then in the File menu, select Export.
3. In the Export Object Type *Object name* To dialog box, in the Save As Type box, select ODBC Databases () as shown here:

4. In the `Export` dialog box, enter a name for the file (or use the suggested name), and then select `OK`.
5. The `Select Data Source` dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the `File Data Source` or `Machine Data Source` tab, and then double-click the `MyODBC` or `MyODBC 3.51` data source that you want to export to. To define a new data source for `MyODBC`, please Section 25.1.9.2, “Configuring a `MyODBC DSN` on Windows”.

Microsoft Access connects to the MySQL Server through this data source and exports new tables and or data.

25.1.11.3. How to Import or Link MySQL Database Tables to Access?

You cannot export a table or query to MySQL database unless you have installed the `MyODBC`.

To import or link a table(s) from MySQL to Access, follow the instructions:

1. Open a database, or switch to the Database window for the open database.
2. To import tables, on the `File` menu, point to `Get External Data`, and then click `Import`. To link tables, on the `File` menu, point to `Get External Data`, and then click `Link Tables`.
3. In the `Import` (or `Link`) dialog box, in the `Files Of Type` box, select `ODBC Databases (.)`. The `Select Data Source` dialog box lists the defined data sources The `Select Data Source` dialog box is displayed; it lists the defined data sources for any ODBC drivers installed on your computer. Click either the `File Data Source` or `Machine Data Source` tab, and then double-click the `MyODBC` or `MyODBC 3.51` data source that you want to export to. To define a new data source for the `MyODBC` or `MyODBC 3.51` driver, please Section 25.1.9.2, “Configuring a `MyODBC DSN` on Windows”.
4. If the ODBC data source that you selected requires you to log on, enter your login ID and password (additional information might also be required), and then click `OK`.
5. Microsoft Access connects to the MySQL server through ODBC data source and displays the list of tables that you can import or link.
6. Click each table that you want to import or link, and then click `OK`. If you're linking a table and it doesn't have an index that uniquely identifies each record, then Microsoft Access displays a list of the fields in the linked table. Click a field or a combination of fields that uniquely identifies each record, and then click `OK`.

25.1.11.4. The Structure or Location of a Linked Table has been Changed. Can I See Those Changes Locally in Linked Tables?

Yes. Use the following procedure to view or to refresh links when the structure or location of a linked table has changed. The Linked Table Manager lists the paths to all currently linked tables.

To view or refresh links:

1. Open the database that contains links to tables.
2. On the **Tools** menu, point to **Add-ins**, and then click **Linked Table Manager**.
3. Select the check box for the tables whose links you want to refresh.
4. Click **OK** to refresh the links.

Microsoft Access confirms a successful refresh or, if the table wasn't found, displays the **Select New Location of <table name>** dialog box in which you can specify its the table's new location. If several selected tables have moved to the new location that you specify, the Linked Table Manager searches that location for all selected tables, and updates all links in one step.

To change the path for a set of linked tables:

1. Open the database that contains links to tables.
2. On the **Tools** menu, point to **Add-ins**, and then click **Linked Table Manager**.
3. Select the **Always Prompt For A New Location** check box.
4. Select the check box for the tables whose links you want to change, and then click **OK**.
5. In the **Select New Location of <table name>** dialog box, specify the new location, click **Open**, and then click **OK**.

25.1.11.5. When I Insert or Update a Record in Linked Tables, I Get #DELETED#

If the inserted or updated records are shown as #DELETED# in the access, then:

- If you are using Access 2000, you should get and install the newest (version 2.6 or higher) Microsoft MDAC (Microsoft Data Access Components) from <http://www.microsoft.com/data/>. This fixes a bug in Access that when you export data to MySQL, the table and column names aren't specified. Another way to work around this bug is to upgrade to MyODBC 2.50.33 and MySQL 3.23.x, which together provide a workaround for the problem.

You should also get and apply the Microsoft Jet 4.0 Service Pack 5 (SP5) which can be found at <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q239114>. This fixes some cases where columns are marked as #DELETED# in Access.

Note: If you are using MySQL 3.22, you must to apply the MDAC patch and use MyODBC 2.50.32 or 2.50.34 and up to work around this problem.

- For all versions of Access, you should enable the **MyODBC Return matching rows** option. For Access 2.0, you should additionally enable the **Simulate ODBC 1.0** option.
- You should have a timestamp in all tables that you want to be able to update. For maximum portability, don't use a length specification in the column declaration. That is, use **TIMESTAMP**, not **TIMESTAMP (n)**, $n < 14$.
- You should have a primary key in the table. If not, new or updated rows may show up as #DELETED#.

- Use only `DOUBLE` float fields. Access fails when comparing with single floats. The symptom usually is that new or updated rows may show up as `#DELETED#` or that you can't find or update rows.
- If you are using MyODBC to link to a table that has a `BIGINT` column, the results are displayed as `#DELETED`. The work around solution is:
 - Have one more dummy column with `TIMESTAMP` as the data type.
 - Select the `Change BIGINT columns to INT` option in the connection dialog in ODBC DSN Administrator.
 - Delete the table link from Access and re-create it.

Old records still display as `#DELETED#`, but newly added/updated records are displayed properly.

25.1.11.6. How Do I Handle Write Conflicts or Row Location Errors?

If you see the following errors, select the `Return Matching Rows` option in the DSN configuration dialog, or specify `OPTION=2`, as the connection parameter:

`Write Conflict. Another user has changed your data.`

`Row cannot be located for updating. Some values may have been changed since it was last read.`

25.1.11.7. Whenever I Export a Table from Access 97, a Strange Syntax Error Occurs

This is a strange issue from Access 97, and doesn't appear with Access 2000 or 2002. You can overcome this by upgrading the MyODBC driver to at least MyODBC 3.51.02.

25.1.11.8. Access Returns Another user has modified the record that you have modified While Editing Records

With some programs, this error may occur: `Another user has modified the record that you have modified`. In most cases, this can be solved by doing one of the following things:

- Add a primary key for the table if one doesn't exist.
- Add a timestamp column if one doesn't exist.
- Only use double float fields. Some programs may fail when they compare single floats.

If these strategies don't help, you should start by making a log file from the ODBC manager (the log you get when requesting logs from ODBCADMIN) and a MyODBC log to help you figure out why things go wrong. For instructions, see Section 25.1.9.7, "Getting an ODBC Trace File".

25.1.11.9. How to Trap ODBC Login Error Messages in Access?

Read "How to Trap ODBC Login Error Messages in Access" at <http://support.microsoft.com/support/kb/articles/Q124/9/01.asp?LN=EN-US&SD=gn&FR=0%3CP%3E>.

25.1.11.10. How Do I Optimize Access for Performance with MyODBC?

- Optimizing for Client/Server Performance [http://support.microsoft.com/default.aspx?scid=kb;en-us;128808]
- Tips for Converting Applications to Using ODBCDirect [http://support.microsoft.com/default.aspx?scid=kb;en-us;164481]
- Tips for Optimizing Queries on Attached SQL Tables [http://support.microsoft.com/default.aspx?scid=kb;EN-US;q99321]

25.1.11.11. I Have Very Long Tables. What is the Best Configuration for MyODBC to Access These Tables?

If you have very large (long) tables in Access, it might take a very long time to open them. Or you might run low on virtual memory and eventually get an ODBC Query Failed error and the table cannot open. To deal with this, select the following options:

- Return Matching Rows (2)
- Allow BIG Results (8).

These add up to a value of 10 (OPTION=10).

25.1.11.12. How to Set the QueryTimeout Value for ODBC Connections?

Read "Set the QueryTimeout Value for ODBC Connections" at <http://support.microsoft.com/default.aspx?scid=kb%3Ben-us%3B153756>.

25.1.11.13. INFO: Tools to Export/Import from/to Access to/from MySQL

Refer to converters [http://www.mysql.com/portal/software/convertors/] section for list of available tools.

25.1.12. MyODBC and Microsoft VBA and ASP

This section answers questions related to using MyODBC with Microsoft Visual Basic(ADO, DAO & RDO) and ASP.

25.1.12.1. Why Does `SELECT COUNT(*) FROM tbl_name` Return an Error?

It's because the `COUNT(*)` expression is returning a `BIGINT`, and ADO can't make sense of a number this big. Select the `Change BIGINT columns to INT` option (option value 16384).

25.1.12.2. Whenever I Use the `AppendChunk()` or `GetChunk()` ADO Methods, I Get an Error Multiple-step operation generated errors. Check each status value.

The `GetChunk()` and `AppendChunk()` methods from ADO doesn't work as expected when the

cursor location is specified as `adUseServer`. On the other hand, you can overcome this error by using `adUseClient`.

A simple example can be found from, http://www.dwam.net/iishelp/ado/docs/adomth02_4.htm

25.1.12.3. How to Find the Total Number of Rows Affected by a Particular SQL Statement in ADO?

You can make use of `RecordsAffected` property in the ADO execute method. For more information on the usage of execute method, refer to <http://msdn.microsoft.com/library/default.asp?url=/library/en-us/ado270/html/mdmthcnnextecute.asp>.

25.1.12.4. How Do I Handle Blob Data in Visual Basic?

Here is an excellent article from Mike Hillyer (<m.hillyer@telusplanet.net>); explaining how to insert and/or fetch data from blob columns through MyODBC from ADO: MySQL BLOB columns and Visual Basic 6 [<http://www.dynamergy.com/mike/articles/blobaccessvb.html>].

25.1.12.5. How Do I Map Visual Basic Data Types to MySQL Types?

Here is yet another good article from Mike Hillyer (<m.hillyer@telusplanet.net>): How to map Visual basic data type to MySQL types [<http://www.dynamergy.com/mike/articles/vbmysqldatatype.php>].

25.1.12.6. SAMPLES: VB with ADO, DAO and RDO

A simple examples for the usage of ADO, DAO and RDO with VB can be found her:

- ADO sample: Section 25.1.19, “MyODBC With VB: ADO, DAO and RDO”
- DAO sample: Section 25.1.19, “MyODBC With VB: ADO, DAO and RDO”
- RDO sample: Section 25.1.19, “MyODBC With VB: ADO, DAO and RDO”

If you find any other good example or HOW-TO on ADO/DAO/RDO, then please send the details to <myodbc@lists.mysql.com>

25.1.12.7. ASP and MySQL with MyODBC

For more information about how to access MySQL via ASP using MyODBC, refer to the following articles:

- Using MyODBC To Access Your MySQL Database Via ASP [<http://www.devarticles.com/c/a/ASP/Using-MyODBC-To-Access-Your-MySQL-Database-Via-ASP/>]
- ASP and MySQL at DWAM.NT [http://www.dwam.net/mysql/asp_myodbc.asp]

A Frequently Asked Questions list for ASP can be found at <http://support.microsoft.com/default.aspx?scid=/Support/ActiveServer/faq/data/adofaq.asp>.

25.1.12.8. INFO: Frequently Asked Questions on ActiveX Data Objects (ADO)

For information, see ActiveX Data Objects(ADO) Frequently Asked Questions [<http://support.microsoft.com/default.aspx?scid=kb;EN-US;q183606>].

25.1.13. MyODBC and Third-Party ODBC Tools

This section answers questions related to MyODBC with various ODBC-related tools; such as Microsoft Word, Excel and ColdFusion.

25.1.13.1. How to Retrieve Data from MySQL into MS-Word/Excel Documents?

To retrieve data from MySQL to Word/Excel documents, you need to use the MyODBC driver and the Add-in Microsoft Query help.

For example, create a database with a table containing two columns of text:

- Insert rows using the **mysql** client command-line tool.
- Create a DSN file using the ODBC manager, for example, my for the database that was just created.
- Open the Word application.
- Create a blank new document.
- In the Database tool bar, press the Insert Database button.
- Press the Get Data button.
- At the right hand of the Get Data screen, press the Ms Query button.
- In Ms Query, create a new data source using the my DSN file.
- Select the new query.
- Select the columns that you want.
- Make a filter if you want.
- Make a Sort if you want.
- Select Return Data to Microsoft Word.
- Click Finish.
- Click Insert Data and select the records.
- Click OK and you see the rows in your Word document.

25.1.13.2. Exporting Tables from MS DTS to MySQL Using MyODBC Results in a Syntax Error

This is an issue similar to that of Access 97 when your table consists of TEXT or VARCHAR data types. You can fix this error by upgrading your MyODBC driver to version 3.51.02 or higher.

25.1.13.3. HOWTO: Configure MySQL+MyODBC+unixODBC+ColdFusion on Solaris

Refer to MySQL ColdFusion unixODBC MyODBC and Solaris - how to succeed [<http://dbforums.com/showthread.php?threadid=174934>]

25.1.14. MyODBC General Functionality

This section of the document answers questions related to MyODBC general functionality.

25.1.14.1. How to Get the Value of an AUTO_INCREMENT Column in ODBC

A common problem is how to get the value of an automatically generated ID from an INSERT statement. With ODBC, you can do something like this (assuming that auto is an AUTO_INCREMENT field):

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
SELECT LAST_INSERT_ID();
```

Or, if you are just going to insert the ID into another table, you can do this:

```
INSERT INTO tbl (auto,text) VALUES(NULL,'text');
INSERT INTO tbl2 (id,text) VALUES(LAST_INSERT_ID(),'text');
```

See Section 24.2.13.3, “How to Get the Unique ID for the Last Inserted Row”.

For the benefit of some ODBC applications (at least Delphi and Access), the following query can be used to find a newly inserted row:

```
SELECT * FROM tbl WHERE auto IS NULL;
```

25.1.14.2. Does MyODBC Support Dynamic Cursor Type?

Yes. MyODBC 3.51 supports `Dynamic cursor` type along with `Forward-only` and `static`.

Due to the performance issues, the driver does not support this feature by default. You can enable this by specifying the connection option flag as `OPTION=32` or by checking the `Enable Dynamic Cursor` option from the DSN configuration.

25.1.14.3. What Causes Transactions are not enabled Errors?

The driver returns this error when an application issues any transactional call but the underlying MySQL server either does not support transactions or they are not enabled.

To avoid this problem, you must use a server that has either or both of the `InnoDB` or `BDB` storage engines enabled, and use tables of those types. MySQL servers from version 4.0 and up support `InnoDB` by default. MySQL-Max servers also support `BDB` on platforms where `BDB` is available.

Also, if your server supports transactional table types (`InnoDB` and `BDB`) make sure the `disable transactions` option is not set from the DSN configuration.

25.1.14.4. What Causes Cursor not found Errors?

This is because the application is using old MyODBC 2.50 version, and it did not set the cursor name explicitly through `SQLSetCursorName`. The fix is to upgrade to MyODBC 3.51 version.

25.1.14.5. Can I Use MyODBC 2.50 Applications with MyODBC 3.51?

Yes. If you find something is not working with MyODBC 3.51 that works with MyODBC 2.50, then send a mail message to [<myodbc@lists.mysql.com>](mailto:myodbc@lists.mysql.com)

25.1.14.6. Can I Access MySQL from .NET Environment Using My-

ODBC?

Yes. You can make use of **odbc.net** to connect to MySQL through MyODBC. Here are the few basic samples to connect to MySQL from VC.NET and VB.NET.

- See Section 25.1.20.1, “ODBC.NET: CSHARP(C#)”
- See Section 25.1.20.2, “ODBC.NET: VB”

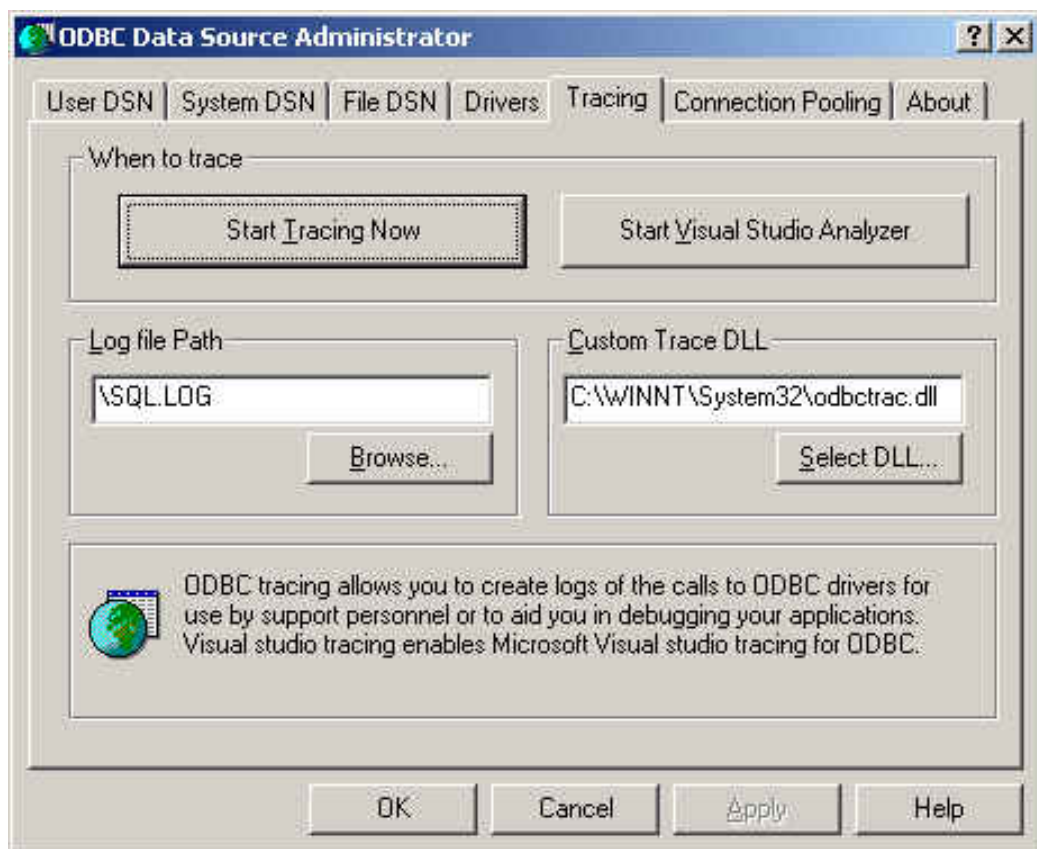

Here is yet another excellent article "Exploring MySQL on .NET environment [<http://www.mysql.com/newsletter/2002-07/a0000000035.html>]" by **Venu** (MyODBC developer) that covers about all MySQL .NET interfaces along with some useful examples.

Caution: Using ODBC.NET with MyODBC, while fetching empty string (0 length), it starts giving the `SQL_NO_DATA` exception. You can get the patch for this from <http://support.microsoft.com/default.aspx?scid=kb;EN-US;q319243>.

25.1.14.7. Why Does MyODBC Perform Poorly, and Also Make a Lot of Disk Activity for Relatively Small Queries?

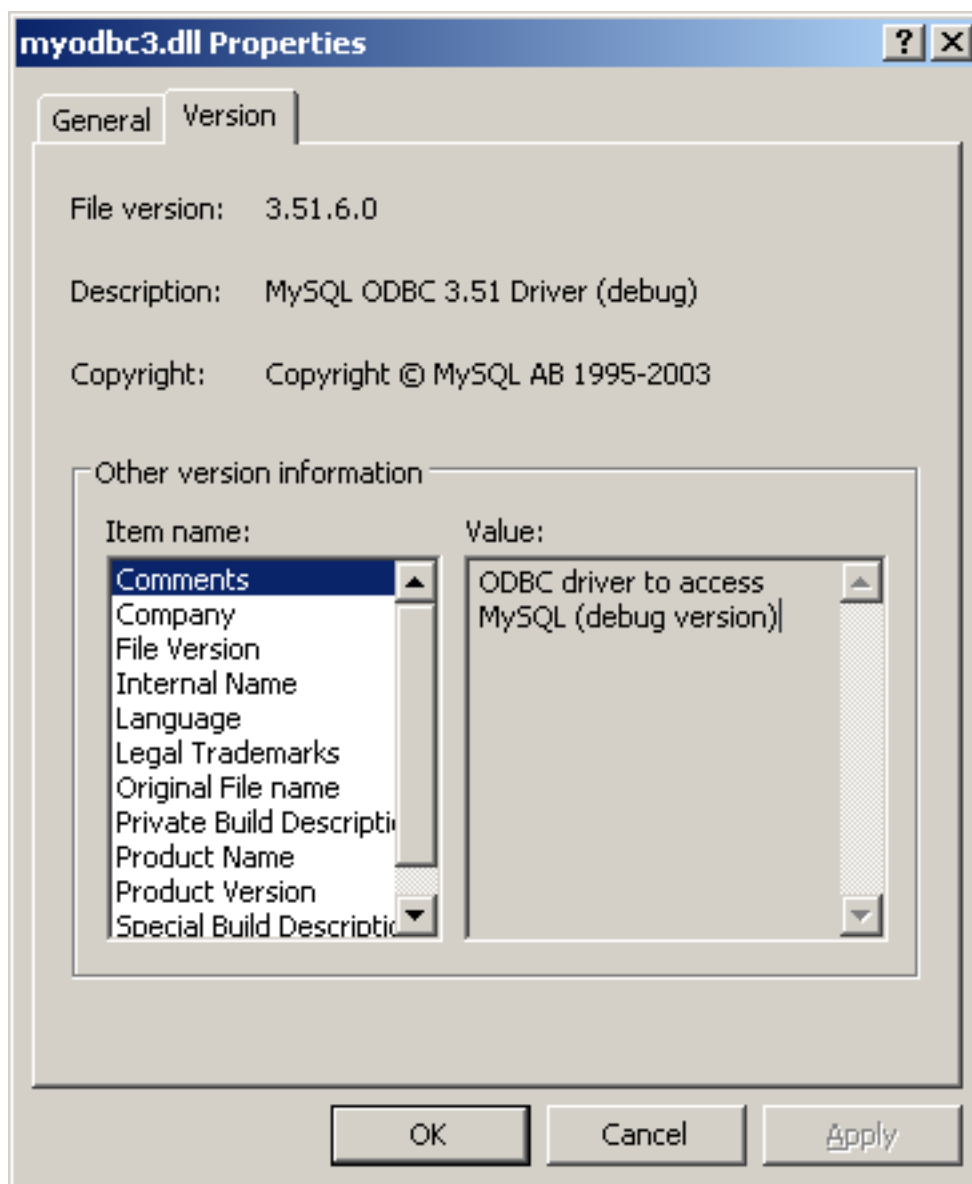

MyODBC is a lot faster than any other ODBC driver. Slowness might be due to not using the following options.

- The **ODBC Tracing** option is turned on. You can cross-check whether this option is not turned on by following the instructions from here [<http://support.microsoft.com/default.aspx?scid=kb;EN-US;268591>].

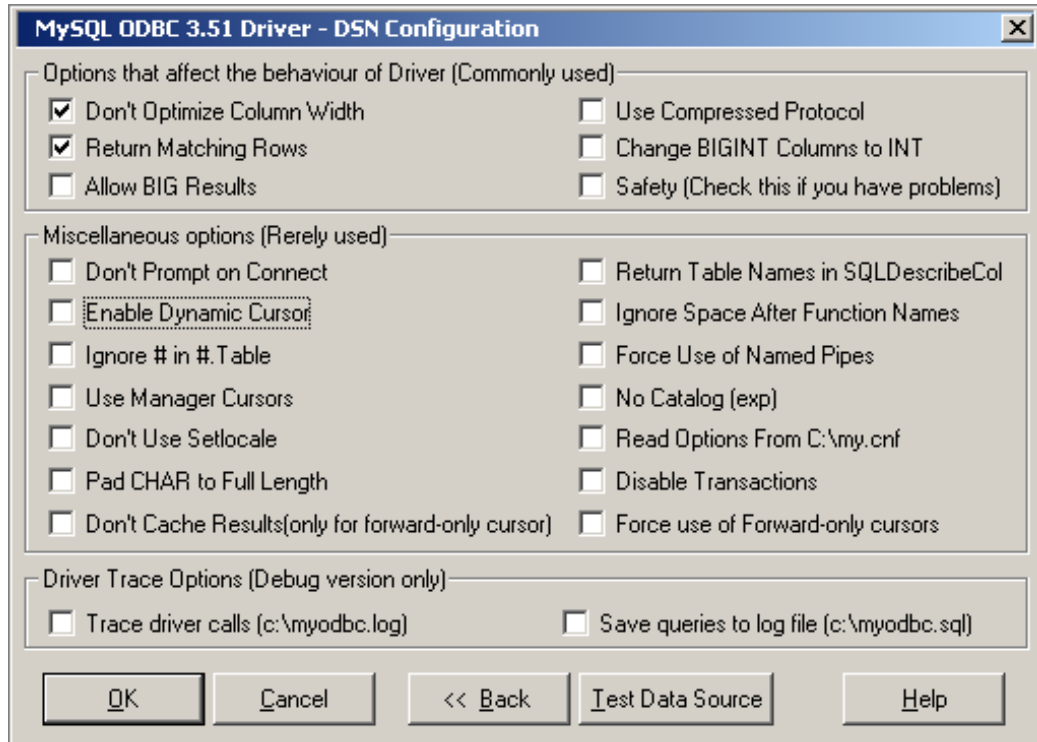

As shown in the above image, the 'When to trace' option from the ODBC Data Source Administrator 'Tracing' tab should always point to 'Start Tracing Now', instead of 'Stop Tracing Now'.

- The **Debug version** of the driver is used. If you are using the debug version of the driver DLL, it can also relatively slow down the query processing time. You can cross-check whether you are using the debug or release version of the DLL from the 'Comments' section of the driver DLL properties (from the system directory, right click on the driver DLL and click on properties) as shown below:

- The **Driver trace and query logs** are enabled. Even if you intent to use the debug version of the driver (you should always use the release version in the production environment), make sure the driver trace and query log options(OPTION=4,524288 respectively) are not enabled as shown below:

25.1.15. Basic MyODBC Application Steps

Interacting with a MySQL server from MyODBC applications involves the following operations:

- Configure the MyODBC DSN
- Connect to MySQL server
- Initialization operations
- Execute SQL statements
- Retrieve results
- Perform Transactions
- Disconnect from the server

Most applications use some variation of these steps. The basic application steps are shown in the following diagram:

25.1.16. MyODBC API Reference

This section summarizes ODBC routines, categorized by functionality.

For the complete ODBC API reference, please refer to the ODBC Programmer's Reference at http://msdn.microsoft.com/library/en-us/odbc/html/odbcabout_this_manual.asp.

An application can call `SQLGetInfo` function to obtain conformance information about MyODBC. To obtain information about support for a specific function in the driver, an application can call `SQLGetFunctions`.

Note: For backward compatibility, the MyODBC 3.51 driver supports all deprecated functions.

The following tables list MyODBC API calls grouped by task:

Connecting to a data source:

Function name	MyODBC 2.50	MyODBC 3.51	Conformance	Purpose
SQLAllocHandle	No	Yes	ISO 92	Obtains an environment, connection, statement, or descriptor handle.
SQLConnect	Yes	Yes	ISO 92	Connects to a specific driver by data source name, user ID, and password.
SQLDriverConnect	Yes	Yes	ODBC	Connects to a specific driver by connection string or requests that the Driver Manager and driver display connection dialog boxes for the user.
SQLAllocEnv	Yes	Yes	Deprecated	Obtains an environment handle allocated from driver.
SQLAllocConnect	Yes	Yes	Deprecated	Obtains a connection handle

Obtaining information about a driver and data source:

Function name	MyODBC 2.50	MyODBC 3.51	Conformance	Purpose
SQLDataSources	No	No	ISO 92	Returns the list of available data sources, handled by the Driver Manager
SQLDrivers	No	No	ODBC	Returns the list of installed drivers and their attributes, handles by Driver Manager
SQLGetInfo	Yes	Yes	ISO 92	Returns information about a specific driver and data source.
SQLGetFunctions	Yes	Yes	ISO 92	Returns supported driver functions.
SQLGetTypeInfo	Yes	Yes	ISO 92	Returns information about supported data types.

Setting and retrieving driver attributes:

Function name	MyODBC 2.50	MyODBC 3.51	Conformance	Purpose
SQLSetConnectAttr	No	Yes	ISO 92	Sets a connection attribute.
SQLGetConnectAttr	No	Yes	ISO 92	Returns the value of a connection attribute.
SQLSetConnectOption	Yes	Yes	Deprecated	Sets a connection option
SQLGetConnectOption	Yes	Yes	Deprecated	Returns the value of a connection option
SQLSetEnvAttr	No	Yes	ISO 92	Sets an environment attribute.
SQLGetEnvAttr	No	Yes	ISO 92	Returns the value of an environment attribute.
SQLSetStmtAttr	No	Yes	ISO 92	Sets a statement attribute.

SQLGetStmtAttr	No	Yes	ISO 92	Returns the value of a statement attribute.
SQLSetStmtOption	Yes	Yes	Deprecated	Sets a statement option
SQLGetStmtOption	Yes	Yes	Deprecated	Returns the value of a statement option

Preparing SQL requests:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	3.51		
SQLAllocStmt	Yes	Yes	Deprecated	Allocates a statement handle
SQLPrepare	Yes	Yes	ISO 92	Prepares an SQL statement for later execution.
SQLBindParameter	Yes	Yes	ODBC	Assigns storage for a parameter in an SQL statement.
SQLGetCursorName	Yes	Yes	ISO 92	Returns the cursor name associated with a statement handle.
SQLSetCursorName	Yes	Yes	ISO 92	Specifies a cursor name.
SQLSetScrollOptions	Yes	Yes	ODBC	Sets options that control cursor behavior.

Submitting requests:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	3.51		
SQLExecute	Yes	Yes	ISO 92	Executes a prepared statement.
SQLExecDirect	Yes	Yes	ISO 92	Executes a statement
SQLNativeSql	Yes	Yes	ODBC	Returns the text of an SQL statement as translated by the driver.
SQLDescribeParam	Yes	Yes	ODBC	Returns the description for a specific parameter in a statement.
SQLNumParams	Yes	Yes	ISO 92	Returns the number of parameters in a statement.
SQLParamData	Yes	Yes	ISO 92	Used in conjunction with SQLPutData to supply parameter data at execution time. (Useful for long data values.)
SQLPutData	Yes	Yes	ISO 92	Sends part or all of a data value for a parameter. (Useful for long data values.)

Retrieving results and information about results:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	3.51		
SQLRowCount	Yes	Yes	ISO 92	Returns the number of rows affected by an insert, update, or delete request.
SQLNumResult-	Yes	Yes	ISO 92	Returns the number of columns in

Cols				the result set.
SQLDescribeCol	Yes	Yes	ISO 92	Describes a column in the result set.
SQLColAttribute	No	Yes	ISO 92	Describes attributes of a column in the result set.
SQLColAttributes	Yes	Yes	Deprecated	Describes attributes of a column in the result set.
SQLFetch	Yes	Yes	ISO 92	Returns multiple result rows.
SQLFetchScroll	No	Yes	ISO 92	Returns scrollable result rows.
SQLExtendedFetch	Yes	Yes	Deprecated	Returns scrollable result rows.
SQLSetPos	Yes	Yes	ODBC	Positions a cursor within a fetched block of data and allows an application to refresh data in the rowset or to update or delete data in the result set.
SQLBulkOperations	No	Yes	ODBC	Performs bulk insertions and bulk bookmark operations, including update, delete, and fetch by bookmark.

Retrieving error or diagnostic information:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	3.51		
SQLError	Yes	Yes	Deprecated	Returns additional error or status information
SQLGetDiagField	Yes	Yes	ISO 92	Returns additional diagnostic information (a single field of the diagnostic data structure).
SQLGetDiagRec	Yes	Yes	ISO 92	Returns additional diagnostic information (multiple fields of the diagnostic data structure).

Obtaining information about the data source's system tables (catalog functions) item:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	3.51		
SQLColumnPrivileges	Yes	Yes	ODBC	Returns a list of columns and associated privileges for one or more tables.
SQLColumns	Yes	Yes	X/Open	Returns the list of column names in specified tables.
SQLForeignKeys	Yes	Yes	ODBC	Returns a list of column names that make up foreign keys, if they exist for a specified table.
SQLPrimaryKeys	Yes	Yes	ODBC	Returns the list of column names that make up the primary key for a table.
SQLSpecialColumns	Yes	Yes	X/Open	Returns information about the optimal set of columns that uniquely identifies a row in a specified table, or the columns that are auto-

				atically updated when any value in the row is updated by a transaction.
SQLStatistics	Yes	Yes	ISO 92	Returns statistics about a single table and the list of indexes associated with the table.
SQLTablePrivileges	Yes	Yes	ODBC	Returns a list of tables and the privileges associated with each table.
SQLTables	Yes	Yes	X/Open	Returns the list of table names stored in a specific data source.

Performing transactions:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	3.51		
SQLTransact	Yes	Yes	Deprecated	Commits or rolls back a transaction
SQLEndTran	No	Yes	ISO 92	Commits or rolls back a transaction.

Terminating a statement:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	3.51		
SQLFreeStmt	Yes	Yes	ISO 92	Ends statement processing, discards pending results, and, optionally, frees all resources associated with the statement handle.
SQLCloseCursor	Yes	Yes	ISO 92	Closes a cursor that has been opened on a statement handle.
SQLCancel	Yes	Yes	ISO 92	Cancels an SQL statement.

Terminating a connection:

Function name	MyODBC	MyODBC	Conformance	Purpose
	2.50	3.51		
SQLDisconnect	Yes	Yes	ISO 92	Closes the connection.
SQLFreeHandle	No	Yes	ISO 92	Releases an environment, connection, statement, or descriptor handle.
SQLFreeConnect	Yes	Yes	Deprecated	Releases connection handle
SQLFreeEnv	Yes	Yes	Deprecated	Releases an environment handle

25.1.17. MyODBC Data Types

The following table illustrates how driver maps the server data types to default SQL and C data types:

Native Value	SQL Type	C Type
--------------	----------	--------

bit	SQL_BIT	SQL_C_BIT
tinyint	SQL_TINYINT	SQL_C_STINYINT
tinyint unsigned	SQL_TINYINT	SQL_C_UTINYINT
bigint	SQL_BIGINT	SQL_C_SBIGINT
bigint unsigned	SQL_BIGINT	SQL_C_UBIGINT
long varbinary	SQL_LONGVARBINARY	SQL_C_BINARY
blob	SQL_LONGVARBINARY	SQL_C_BINARY
longblob	SQL_LONGVARBINARY	SQL_C_BINARY
tinyblob	SQL_LONGVARBINARY	SQL_C_BINARY
mediumblob	SQL_LONGVARBINARY	SQL_C_BINARY
long varchar	SQL_LONGVARCHAR	SQL_C_CHAR
text	SQL_LONGVARCHAR	SQL_C_CHAR
mediumtext	SQL_LONGVARCHAR	SQL_C_CHAR
char	SQL_CHAR	SQL_C_CHAR
numeric	SQL_NUMERIC	SQL_C_CHAR
decimal	SQL_DECIMAL	SQL_C_CHAR
integer	SQL_INTEGER	SQL_C_SLONG
integer unsigned	SQL_INTEGER	SQL_C_ULONG
int	SQL_INTEGER	SQL_C_SLONG
int unsigned	SQL_INTEGER	SQL_C_ULONG
mediumint	SQL_INTEGER	SQL_C_SLONG
mediumint unsigned	SQL_INTEGER	SQL_C_ULONG
smallint	SQL_SMALLINT	SQL_C_SSHORT
smallint unsigned	SQL_SMALLINT	SQL_C_USHORT
real	SQL_FLOAT	SQL_C_DOUBLE
double	SQL_FLOAT	SQL_C_DOUBLE
float	SQL_REAL	SQL_C_FLOAT
double precision	SQL_DOUBLE	SQL_C_DOUBLE
date	SQL_DATE	SQL_C_DATE
time	SQL_TIME	SQL_C_TIME
year	SQL_SMALLINT	SQL_C_SHORT
datetime	SQL_TIMESTAMP	SQL_C_TIMESTAMP
timestamp	SQL_TIMESTAMP	SQL_C_TIMESTAMP
text	SQL_VARCHAR	SQL_C_CHAR
varchar	SQL_VARCHAR	SQL_C_CHAR
enum	SQL_VARCHAR	SQL_C_CHAR
set	SQL_VARCHAR	SQL_C_CHAR
bit	SQL_CHAR	SQL_C_CHAR
bool	SQL_CHAR	SQL_C_CHAR

25.1.18. MyODBC Error Codes

The following tables lists the error codes returned by the driver apart from the server errors.

Native Code	SQLSTATE 2	SQLSTATE 3	Error Message
-------------	------------	------------	---------------

500	01000	01000	General warning
501	01004	01004	String data, right truncated
502	01S02	01S02	Option value changed
503	01S03	01S03	No rows updated/deleted
504	01S04	01S04	More than one row updated/deleted
505	01S06	01S06	Attempt to fetch before the result set returned the first row set
506	07001	07002	SQLBindParameter not used for all parameters
507	07005	07005	Prepared statement not a cursor-specification
508	07009	07009	Invalid descriptor index
509	08002	08002	Connection name in use
510	08003	08003	Connection does not exist
511	24000	24000	Invalid cursor state
512	25000	25000	Invalid transaction state
513	25S01	25S01	Transaction state unknown
514	34000	34000	Invalid cursor name
515	S1000	HY000	General driver defined error
516	S1001	HY001	Memory allocation error
517	S1002	HY002	Invalid column number
518	S1003	HY003	Invalid application buffer type
519	S1004	HY004	Invalid SQL data type
520	S1009	HY009	Invalid use of null pointer
521	S1010	HY010	Function sequence error
522	S1011	HY011	Attribute can not be set now
523	S1012	HY012	Invalid transaction operation code
524	S1013	HY013	Memory management error
525	S1015	HY015	No cursor name available
526	S1024	HY024	Invalid attribute value
527	S1090	HY090	Invalid string or buffer length
528	S1091	HY091	Invalid descriptor field identifier
529	S1092	HY092	Invalid attribute/option identifier
530	S1093	HY093	Invalid parameter number
531	S1095	HY095	Function type out of range
532	S1106	HY106	Fetch type out of range
533	S1117	HY117	Row value out of range
534	S1109	HY109	Invalid cursor position
535	S1C00	HYC00	Optional feature not implemented
0	21S01	21S01	Column count does not match value count
0	23000	23000	Integrity constraint violation
0	42000	42000	Syntax error or access violation
0	42S02	42S02	Base table or view not found
0	42S12	42S12	Index not found
0	42S21	42S21	Column already exists
0	42S22	42S22	Column not found

0	08S01	08S01	Communication link failure
---	-------	-------	----------------------------

25.1.19. MyODBC With VB: ADO, DAO and RDO

This section contains simple examples of the use of MySQL ODBC 3.51 Driver with ADO, DAO and RDO.

25.1.19.1. ADO: rs.addNew, rs.delete, and rs.update

The following ADO (ActiveX Data Objects) example creates a table my_ado and demonstrates the use of rs.addNew, rs.delete, and rs.update.

```
Private Sub myodbc_ado_Click()

    Dim conn As ADODB.Connection
    Dim rs As ADODB.Recordset
    Dim fld As ADODB.Field
    Dim sql As String

    'connect to MySQL server using MySQL ODBC 3.51 Driver
    Set conn = New ADODB.Connection
    conn.ConnectionString = "DRIVER={MySQL ODBC 3.51 Driver};"_
        & "SERVER=localhost;"_
        & " DATABASE=test;"_

rs.Close
conn.Close
End Sub
```

25.1.19.2. DAO: rs.addNew, rs.update, and Scrolling

The following DAO (Data Access Objects) example creates a table my_dao and demonstrates the use of rs.addNew, rs.update, and result set scrolling.

```
Private Sub myodbc_dao_Click()

Dim ws As Workspace
Dim conn As Connection
Dim queryDef As queryDef
Dim str As String

'connect to MySQL using MySQL ODBC 3.51 Driver
Set ws = DBEngine.CreateWorkspace("", "venu", "venu", dbUseODBC)
str = "odbc;DRIVER={MySQL ODBC 3.51 Driver};"_
    & "SERVER=localhost;"_
    & " DATABASE=test;"_
    & "UID=venu;PWD=venu; OPTION=3"
Set conn = ws.OpenConnection("test", dbDriverNoPrompt, False, str)

'Create table my_dao
Set queryDef = conn.CreateQueryDef("", "drop table if exists my_dao")
```

```

queryDef.Execute

Set queryDef = conn.CreateQueryDef("", "create table my_dao(Id INT AUTO_INCREMENT PRIMARY KEY, Name VARCHAR(255), Ts TIMESTAMP(14) NULL)")
queryDef.Execute

'Insert new records using rs.addNew
Set rs = conn.OpenRecordset("my_dao")
Dim i As Integer

    For i = 10 To 15
        rs.AddNew
        rs!Name = "insert record" & i
        rs!Id2 = i
        rs.Update
    Next i
        rs.Close

'rs update..
Set rs = conn.OpenRecordset("my_dao")
rs.Edit
rs!Name = "updated-string"
rs.Update
rs.Close

'fetch the table back...
Set rs = conn.OpenRecordset("my_dao", dbOpenDynamic)
str = "Results:"
rs.MoveFirst
While Not rs.EOF
str = " " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print "DATA:" & str
rs.MoveNext
Wend

'rs Scrolling
rs.MoveFirst
str = " FIRST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MoveLast
str = " LAST ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

rs.MovePrevious
str = " LAST-1 ROW: " & rs!Id & " , " & rs!Name & " , " & rs!Ts & " , " & rs!Id2
Debug.Print str

'free all resources
rs.Close
queryDef.Close
conn.Close
ws.Close

End Sub

```

25.1.19.3. RDO: rs.addNew and rs.update

The following RDO (Remote Data Objects) example creates a table my_rdo and demonstrates the use of rs.addNew and rs.update.

```

Dim rs As rdoResultset
Dim cn As New rdoConnection
Dim cl As rdoColumn
Dim SQL As String

'cn.Connect = "DSN=test;"

```

```

cn.Connect = "DRIVER={MySQL ODBC 3.51 Driver};"_
            & "SERVER=localhost;"_
            & " DATABASE=test;"_
            & "UID=venu;PWD=venu; OPTION=3"

cn.CursorDriver = rdUseOdbc
cn.EstablishConnection rdDriverPrompt

'drop table my_rdo
SQL = "drop table if exists my_rdo"
cn.Execute SQL, rdExecDirect

'create table my_rdo
SQL = "create table my_rdo(id int, name varchar(20))"
cn.Execute SQL, rdExecDirect

'insert - direct
SQL = "insert into my_rdo values (100,'venu')"
cn.Execute SQL, rdExecDirect

SQL = "insert into my_rdo values (200,'MySQL')"
cn.Execute SQL, rdExecDirect

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 300
rs!Name = "Insert1"
rs.Update
rs.Close

'rs insert
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.AddNew
rs!id = 400
rs!Name = "Insert 2"
rs.Update
rs.Close

'rs update
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
rs.Edit
rs!id = 999
rs!Name = "updated"
rs.Update
rs.Close

'fetch back...
SQL = "select * from my_rdo"
Set rs = cn.OpenResultset(SQL, rdOpenStatic, rdConcurRowVer, rdExecDirect)
Do Until rs.EOF
For Each cl In rs.rdoColumns
    Debug.Print cl.Value,
Next
rs.MoveNext
Debug.Print
Loop
Debug.Print "Row count="; rs.RowCount

'close
rs.Close
cn.Close

End Sub

```

25.1.20. MyODBC with Microsoft .NET

This section contains simple examples that demonstrate the use of MyODBC drivers with ODBC.NET.

25.1.20.1. ODBC.NET: CSHARP(C#)

The following sample creates a table `my_odbc_net` and demonstrates the use in C#.

```

/**
 * @sample      : mycon.cs
 * @purpose     : Demo sample for ODBC.NET using MyODBC
 * @author      : Venu, <venu@mysql.com>
 *
 * (C) Copyright MySQL AB, 1995-2004
 *
 **/

/* build command
 *
 * csc /t:exe
 *      /out:mycon.exe mycon.cs
 *      /r:Microsoft.Data.Odbc.dll
 */

using Console = System.Console;
using Microsoft.Data.Odbc;

namespace myodbc3
{
    class mycon
    {
        static void Main(string[] args)
        {
            try
            {
                //Connection string for MyODBC 2.50
                /*string MyConString = "DRIVER={MySQL};" +
                    "SERVER=localhost;" +
                    "DATABASE=test;" +
                    "UID=venu;" +
                    "PASSWORD=venu;" +
                    "OPTION=3";

                */
                //Connection string for MyODBC 3.51
                string MyConString = "DRIVER={MySQL ODBC 3.51 Driver};" +
                    "SERVER=localhost;" +
                    "DATABASE=test;" +
                    "UID=venu;" +
                    "PASSWORD=venu;" +
                    "OPTION=3";

                //Connect to MySQL using MyODBC
                OdbcConnection MyConnection = new OdbcConnection(MyConString);
                MyConnection.Open();

                Console.WriteLine("\n !!! success, connected successfully !!!\n");

                //Display connection information
                Console.WriteLine("Connection Information:");
                Console.WriteLine("\tConnection String:" + MyConnection.ConnectionString);
                Console.WriteLine("\tConnection Timeout:" + MyConnection.ConnectionTimeout);
                Console.WriteLine("\tDatabase:" + MyConnection.Database);
                Console.WriteLine("\tDataSource:" + MyConnection.DataSource);
                Console.WriteLine("\tDriver:" + MyConnection.Driver);
                Console.WriteLine("\tServerVersion:" + MyConnection.ServerVersion);
            }
            catch { }
        }
    }
}

25.1.21. Credits

These are the developers that have worked on the MyODBC and MyODBC 3.51 Drivers from MySQL AB.

- Micheal (Monty) Widenius
- Venu Anuganti
- Peter Harvey

25.2. MySQL Java Connectivity (JDBC)

There are two supported JDBC drivers for MySQL:

- MySQL Connector/J from MySQL AB, implemented in 100% native Java. This product was formerly known as the mm.mysql driver. You can download MySQL Connector/J from <http://dev.mysql.com/downloads/connector/j/>.
- The Resin JDBC driver, which can be found at <http://www.caucho.com/projects/jdbc-mysql/index.xtp>.

For more information, consult any general JDBC documentation, plus each driver's own documentation for MySQL-specific features.

Documentation for MySQL Connector/J is available online at the MySQL AB Web site at <http://dev.mysql.com/doc/>.

Chapter 26. Error Handling in MySQL

This chapter lists the errors that may appear when you call MySQL from any host language. The first list displays server error messages. The second list displays client program messages.

Server error information comes from the following files:

- The Error values and the symbols in parentheses correspond to definitions in the `include/mysql_error.h` MySQL source file.
- The SQLSTATE values correspond to definitions in the `include/sql_state.h` MySQL source file.

SQLSTATE error codes are displayed only if you use MySQL version 4.1 and up. SQLSTATE codes were added for compatibility with X/Open, ANSI, and ODBC behavior.

- The Message values correspond to the error messages that are listed in the `sql/share/english/errmsg.txt` file. %d or %s represent numbers or strings that are substituted into the messages % when they are displayed.

Because updates are frequent, it is possible that these files contain additional error information not listed here.

- Error: 1000 SQLSTATE: HY000 (ER_HASHCHK)
Message: hashchk
- Error: 1001 SQLSTATE: HY000 (ER_NISAMCHK)
Message: isamchk
- Error: 1002 SQLSTATE: HY000 (ER_NO)
Message: NO
- Error: 1003 SQLSTATE: HY000 (ER_YES)
Message: YES
- Error: 1004 SQLSTATE: HY000 (ER_CANT_CREATE_FILE)
Message: Can't create file '%s' (errno: %d)
- Error: 1005 SQLSTATE: HY000 (ER_CANT_CREATE_TABLE)
Message: Can't create table '%s' (errno: %d)
- Error: 1006 SQLSTATE: HY000 (ER_CANT_CREATE_DB)
Message: Can't create database '%s' (errno: %d)
- Error: 1007 SQLSTATE: HY000 (ER_DB_CREATE_EXISTS)
Message: Can't create database '%s'; database exists
- Error: 1008 SQLSTATE: HY000 (ER_DB_DROP_EXISTS)
Message: Can't drop database '%s'; database doesn't exist
- Error: 1009 SQLSTATE: HY000 (ER_DB_DROP_DELETE)

- Message: Error dropping database (can't delete '%s', errno: %d)
- Error: 1010 SQLSTATE: HY000 (ER_DB_DROP_RMDIR)
Message: Error dropping database (can't rmdir '%s', errno: %d)
- Error: 1011 SQLSTATE: HY000 (ER_CANT_DELETE_FILE)
Message: Error on delete of '%s' (errno: %d)
- Error: 1012 SQLSTATE: HY000 (ER_CANT_FIND_SYSTEM_REC)
Message: Can't read record in system table
- Error: 1013 SQLSTATE: HY000 (ER_CANT_GET_STAT)
Message: Can't get status of '%s' (errno: %d)
- Error: 1014 SQLSTATE: HY000 (ER_CANT_GET_WD)
Message: Can't get working directory (errno: %d)
- Error: 1015 SQLSTATE: HY000 (ER_CANT_LOCK)
Message: Can't lock file (errno: %d)
- Error: 1016 SQLSTATE: HY000 (ER_CANT_OPEN_FILE)
Message: Can't open file: '%s' (errno: %d)
- Error: 1017 SQLSTATE: HY000 (ER_FILE_NOT_FOUND)
Message: Can't find file: '%s' (errno: %d)
- Error: 1018 SQLSTATE: HY000 (ER_CANT_READ_DIR)
Message: Can't read dir of '%s' (errno: %d)
- Error: 1019 SQLSTATE: HY000 (ER_CANT_SET_WD)
Message: Can't change dir to '%s' (errno: %d)
- Error: 1020 SQLSTATE: HY000 (ER_CHECKREAD)
Message: Record has changed since last read in table '%s'
- Error: 1021 SQLSTATE: HY000 (ER_DISK_FULL)
Message: Disk full (%s); waiting for someone to free some space...
- Error: 1022 SQLSTATE: 23000 (ER_DUP_KEY)
Message: Can't write; duplicate key in table '%s'
- Error: 1023 SQLSTATE: HY000 (ER_ERROR_ON_CLOSE)
Message: Error on close of '%s' (errno: %d)
- Error: 1024 SQLSTATE: HY000 (ER_ERROR_ON_READ)
Message: Error reading file '%s' (errno: %d)
- Error: 1025 SQLSTATE: HY000 (ER_ERROR_ON_RENAME)

- Message: Error on rename of '%s' to '%s' (errno: %d)
- Error: 1026 SQLSTATE: HY000 (ER_ERROR_ON_WRITE)
Message: Error writing file '%s' (errno: %d)
- Error: 1027 SQLSTATE: HY000 (ER_FILE_USED)
Message: '%s' is locked against change
- Error: 1028 SQLSTATE: HY000 (ER_FILSORT_ABORT)
Message: Sort aborted
- Error: 1029 SQLSTATE: HY000 (ER_FORM_NOT_FOUND)
Message: View '%s' doesn't exist for '%s'
- Error: 1030 SQLSTATE: HY000 (ER_GET_ERRNO)
Message: Got error %d from storage engine
- Error: 1031 SQLSTATE: HY000 (ER_ILLEGAL HA)
Message: Table storage engine for '%s' doesn't have this option
- Error: 1032 SQLSTATE: HY000 (ER_KEY_NOT_FOUND)
Message: Can't find record in '%s'
- Error: 1033 SQLSTATE: HY000 (ER_NOT_FORM_FILE)
Message: Incorrect information in file: '%s'
- Error: 1034 SQLSTATE: HY000 (ER_NOT_KEYFILE)
Message: Incorrect key file for table '%s'; try to repair it
- Error: 1035 SQLSTATE: HY000 (ER_OLD_KEYFILE)
Message: Old key file for table '%s'; repair it!
- Error: 1036 SQLSTATE: HY000 (ER_OPEN_AS_READONLY)
Message: Table '%s' is read only
- Error: 1037 SQLSTATE: HY001 (ER_OUTOFMEMORY)
Message: Out of memory; restart server and try again (needed %d bytes)
- Error: 1038 SQLSTATE: HY001 (ER_OUT_OF_SORTMEMORY)
Message: Out of sort memory; increase server sort buffer size
- Error: 1039 SQLSTATE: HY000 (ER_UNEXPECTED_EOF)
Message: Unexpected EOF found when reading file '%s' (errno: %d)
- Error: 1040 SQLSTATE: 08004 (ER_CON_COUNT_ERROR)
Message: Too many connections
- Error: 1041 SQLSTATE: HY000 (ER_OUT_OF_RESOURCES)

Message: Out of memory; check if mysqld or some other process uses all available memory; if not, you may have to use 'ulimit' to allow mysqld to use more memory or you can add more swap space

- Error: 1042 SQLSTATE: 08S01 (ER_BAD_HOST_ERROR)

Message: Can't get hostname for your address

- Error: 1043 SQLSTATE: 08S01 (ER_HANDSHAKE_ERROR)

Message: Bad handshake

- Error: 1044 SQLSTATE: 42000 (ER_DBACCESS_DENIED_ERROR)

Message: Access denied for user '%s'@'%s' to database '%s'

- Error: 1045 SQLSTATE: 28000 (ER_ACCESS_DENIED_ERROR)

Message: Access denied for user '%s'@'%s' (using password: %s)

- Error: 1046 SQLSTATE: 3D000 (ER_NO_DB_ERROR)

Message: No database selected

- Error: 1047 SQLSTATE: 08S01 (ER_UNKNOWN_COM_ERROR)

Message: Unknown command

- Error: 1048 SQLSTATE: 23000 (ER_BAD_NULL_ERROR)

Message: Column '%s' cannot be null

- Error: 1049 SQLSTATE: 42000 (ER_BAD_DB_ERROR)

Message: Unknown database '%s'

- Error: 1050 SQLSTATE: 42S01 (ER_TABLE_EXISTS_ERROR)

Message: Multiple primary key defined
- Error: 1069 SQLSTATE: 42000 (ER_TOO_MANY_KEYS)
Message: Too many keys specified; max %d keys allowed
- Error: 1070 SQLSTATE: 42000 (ER_TOO_MANY_KEY_PARTS)
Message: Too many key parts specified; max %d parts allowed
- Error: 1071 SQLSTATE: 42000 (ER_TOO_LONG_KEY)
Message: Specified key was too long; max key length is %d bytes
- Error: 1072 SQLSTATE: 42000 (ER_KEY_COLUMN_DOES_NOT_EXIST)
Message: Key column '%s' doesn't exist in table
- Error: 1073 SQLSTATE: 42000 (ER_BLOB_USED_AS_KEY)

Message: BLOB column '%s' can't be used in key specification with the used table type

- Error: 1074 SQLSTATE: 42000 (ER_TOO_BIG_FIELDLENGTH)

Message: Column length too big for column '%s' (max = %d); use BLOB or TEXT instead

- Error: 1075 SQLSTATE: 42000 (ER_WRONG_AUTO_KEY)

Message: Incorrect table definition; there can be only one auto column and it must be defined as a key

- Error: 1076 SQLSTATE: HY000 (ER_READY)

Message: %s: ready for connections. Version: '%s' socket: '%s' port: %d

- Error: 1077 SQLSTATE: HY000 (ER_NORMAL_SHUTDOWN)

Message: %s: Normal shutdown

- Error: 1078 SQLSTATE: HY000 (ER_GOT_SIGNAL)

Message: %s: Got signal %d. Aborting!

- Error: 1079 SQLSTATE: HY000 (ER_SHUTDOWN_COMPLETE)

Message: %s: Shutdown complete

- Error: 1080 SQLSTATE: 08S01 (ER_FORCING_CLOSE)

Message: %s: Forcing close of thread %ld user: '%s'

- Error: 1081 SQLSTATE: 08S01 (ER_IPSOCK_ERROR)

Message: Can't create IP socket

- Error: 1082 SQLSTATE: 42S12 (ER_NO_SUCH_INDEX)

Message: Table '%s' has no index like the one used in CREATE INDEX; recreate the table

- Error: 1083 SQLSTATE: 42000 (ER_WRONG_FIELD_TERMINATORS)

Message: Field separator argument is not what is expected; check the manual

- Error: 1084 SQLSTATE: 42000 (ER_BLOBS_AND_NO_TERMINATED)

Message: You can't use fixed rowlength with BLOBs; please use 'fields terminated by'

- Error: 1085 SQLSTATE: HY000 (ER_TEXTFILE_NOT_READABLE)

Message: The file '%s' must be in the database directory or be readable by all

- Error: 1086 SQLSTATE: HY000 (ER_FILE_EXISTS_ERROR)

Message: File '%s' already exists

- Error: 1087 SQLSTATE: HY000 (ER_LOAD_INFO)

Message: Records: %ld Deleted: %ld Skipped: %ld Warnings: %ld

- Error: 1088 SQLSTATE: HY000 (ER_ALTER_INFO)

Message: Records: %ld Duplicates: %ld

- Error: 1089 SQLSTATE: HY000 (ER_WRONG_SUB_KEY)

Message: Incorrect sub part key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique sub keys

- Error: 1090 SQLSTATE: 42000 (ER_CANT_REMOVE_ALL_FIELDS)

Message: You can't delete all columns with ALTER TABLE; use DROP TABLE instead

- Error: 1091 SQLSTATE: 42000 (ER_CANT_DROP_FIELD_OR_KEY)

Message: Can't DROP '%s'; check that column/key exists

- Error: 1092 SQLSTATE: HY000 (ER_INSERT_INFO)

Message: Records: %ld Duplicates: %ld Warnings: %ld

- Error: 1093 SQLSTATE: HY000 (ER_UPDATE_TABLE_USED)

Message: You can't specify target table '%s' for update in FROM clause

- Error: 1094 SQLSTATE: HY000 (ER_NO_SUCH_THREAD)

Message: Unknown thread id: %lu

- Error: 1095 SQLSTATE: HY000 (ER_KILL_DENIED_ERROR)

Message: You are not owner of thread %lu

- Error: 1096 SQLSTATE: HY000 (ER_NO_TABLES_USED)

Message: No tables used

- Error: 1097 SQLSTATE: HY000 (ER_TOO_BIG_SET)

Message: Too many strings for column %s and SET

- Error: 1098 SQLSTATE: HY000 (ER_NO_UNIQUE_LOGFILE)

Message: Can't generate a unique log-filename %s.(1-999)

- Error: 1099 SQLSTATE: HY000 (ER_TABLE_NOT_LOCKED_FOR_WRITE)

Message: Table '%s' was locked with a READ lock and can't be updated

- Error: 1100 SQLSTATE: HY000 (ER_TABLE_NOT_LOCKED)

Message: Table '%s' was not locked with LOCK TABLES

- Error: 1101 SQLSTATE: 42000 (ER_BLOB_CANT_HAVE_DEFAULT)

Message: BLOB/TEXT column '%s' can't have a default value

- Error: 1102 SQLSTATE: 42000 (ER_WRONG_DB_NAME)

Message: Incorrect database name '%s'

- Error: 1103 SQLSTATE: 42000 (ER_WRONG_TABLE_NAME)

Message: Incorrect table name '%s'

- Error: 1104 SQLSTATE: 42000 (ER_TOO_BIG_SELECT)

Message: The SELECT would examine more than MAX_JOIN_SIZE rows; check your WHERE and use SET SQL_BIG_SELECTS=1 or SET SQL_MAX_JOIN_SIZE=# if the SELECT is okay

- Error: 1105 SQLSTATE: HY000 (ER_UNKNOWN_ERROR)
Message: Unknown error
- Error: 1106 SQLSTATE: 42000 (ER_UNKNOWN_PROCEDURE)
Message: Unknown procedure '%s'
- Error: 1107 SQLSTATE: 42000 (ER_WRONG_PARAMCOUNT_TO_PROCEDURE)
Message: Incorrect parameter count to procedure '%s'
- Error: 1108 SQLSTATE: HY000 (ER_WRONG_PARAMETERS_TO_PROCEDURE)
Message: Incorrect parameters to procedure '%s'
- Error: 1109 SQLSTATE: 42S02 (ER_UNKNOWN_TABLE)
Message: Unknown table '%s' in %s
- Error: 1110 SQLSTATE: 42000 (ER_FIELD_SPECIFIED_TWICE)
Message: Column '%s' specified twice
- Error: 1111 SQLSTATE: HY000 (ER_INVALID_GROUP_FUNC_USE)
Message: Invalid use of group function
- Error: 1112 SQLSTATE: 42000 (ER_UNSUPPORTED_EXTENSION)
Message: Table '%s' uses an extension that doesn't exist in this MySQL version
- Error: 1113 SQLSTATE: 42000 (ER_TABLE_MUST_HAVE_COLUMNS)
Message: A table must have at least 1 column
- Error: 1114 SQLSTATE: HY000 (ER_RECORD_FILE_FULL)
Message: The table '%s' is full
- Error: 1115 SQLSTATE: 42000 (ER_UNKNOWN_CHARACTER_SET)
Message: Unknown character set: '%s'
- Error: 1116 SQLSTATE: HY000 (ER_TOO_MANY_TABLES)
Message: Too many tables; MySQL can only use %d tables in a join
- Error: 1117 SQLSTATE: HY000 (ER_TOO_MANY_FIELDS)
Message: Too many columns
- Error: 1118 SQLSTATE: 42000 (ER_TOO_BIG_ROWSIZE)
Message: Row size too large. The maximum row size for the used table type, not counting BLOBs, is %ld. You have to change some columns to TEXT or BLOBs
- Error: 1119 SQLSTATE: HY000 (ER_STACK_OVERRUN)
Message: Thread stack overrun: Used: %ld of a %ld stack. Use 'mysqld -O thread_stack=#' to specify a bigger stack if needed
- Error: 1120 SQLSTATE: 42000 (ER_WRONG_OUTER_JOIN)
Message: Cross dependency found in OUTER JOIN; examine your ON conditions

- Error: 1121 SQLSTATE: 42000 (ER_NULL_COLUMN_IN_INDEX)
Message: Column '%s' is used with UNIQUE or INDEX but is not defined as NOT NULL
- Error: 1122 SQLSTATE: HY000 (ER_CANT_FIND_UDF)
Message: Can't load function '%s'
- Error: 1123 SQLSTATE: HY000 (ER_CANT_INITIALIZE_UDF)
Message: Can't initialize function '%s'; %s
- Error: 1124 SQLSTATE: HY000 (ER_UDF_NO_PATHS)
Message: No paths allowed for shared library
- Error: 1125 SQLSTATE: HY000 (ER_UDF_EXISTS)
Message: Function '%s' already exists
- Error: 1126 SQLSTATE: HY000 (ER_CANT_OPEN_LIBRARY)
Message: Can't open shared library '%s' (errno: %d %s)
- Error: 1127 SQLSTATE: HY000 (ER_CANT_FIND_DL_ENTRY)
Message: Can't find function '%s' in library'
- Error: 1128 SQLSTATE: HY000 (ER_FUNCTION_NOT_DEFINED)
Message: Function '%s' is not defined
- Error: 1129 SQLSTATE: HY000 (ER_HOST_IS_BLOCKED)
Message: Host '%s' is blocked because of many connection errors; unblock with 'mysqladmin flush-hosts'
- Error: 1130 SQLSTATE: HY000 (ER_HOST_NOT_PRIVILEGED)
Message: Host '%s' is not allowed to connect to this MySQL server
- Error: 1131 SQLSTATE: 42000 (ER_PASSWORD_ANONYMOUS_USER)
Message: You are using MySQL as an anonymous user and anonymous users are not allowed to change passwords
- Error: 1132 SQLSTATE: 42000 (ER_PASSWORD_NOT_ALLOWED)
Message: You must have privileges to update tables in the mysql database to be able to change passwords for others
- Error: 1133 SQLSTATE: 42000 (ER_PASSWORD_NO_MATCH)
Message: Can't find any matching row in the user table
- Error: 1134 SQLSTATE: HY000 (ER_UPDATE_INFO)
Message: Rows matched: %ld Changed: %ld Warnings: %ld
- Error: 1135 SQLSTATE: HY000 (ER_CANT_CREATE_THREAD)
Message: Can't create a new thread (errno %d); if you are not out of available memory, you can consult the manual for a possible OS-dependent bug
- Error: 1136 SQLSTATE: 21S01 (ER_WRONG_VALUE_COUNT_ON_ROW)

Message: Column count doesn't match value count at row %ld

- Error: 1137 SQLSTATE: HY000 (ER_CANT_REOPEN_TABLE)

Message: Can't reopen table: '%s'

- Error: 1138 SQLSTATE: 22004 (ER_INVALID_USE_OF_NULL)

Message: Invalid use of NULL value

- Error: 1139 SQLSTATE: 42000 (ER_REGEX_ERROR)

Message: Got error '%s' from regexp

- Error: 1140 SQLSTATE: 42000 (ER_MIX_OF_GROUP_FUNC_AND_FIELDS)

Message: Mixing of GROUP columns (MIN(),MAX(),COUNT(),...) with no GROUP columns is illegal if there is no GROUP BY clause

- Error: 1141 SQLSTATE: 42000 (ER_NONEXISTING_GRANT)

Message: There is no such grant defined for user '%s' on host '%s'

- Error: 1142 SQLSTATE: 42000 (ER_TABLEACCESS_DENIED_ERROR)

Message: %s command denied to user '%s'@'%s' for table '%s'

- Error: 1143 SQLSTATE: 42000 (ER_COLUMNACCESS_DENIED_ERROR)

Message: %s command denied to user '%s'@'%s' for column '%s' in table '%s'

- Error: 1144 SQLSTATE: 42000 (ER_ILLEGAL_GRANT_FOR_TABLE)

Message: Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used

- Error: 1145 SQLSTATE: 42000 (ER_GRANT_WRONG_HOST_OR_USER)

Message: The host or user argument to GRANT is too long

- Error: 1146 SQLSTATE: 42S02 (ER_NO_SUCH_TABLE)

Message: Table '%s.%s' doesn't exist

- Error: 1147 SQLSTATE: 42000 (ER_NONEXISTING_TABLE_GRANT)

Message: There is no such grant defined for user '%s' on host '%s' on table '%s'

- Error: 1148 SQLSTATE: 42000 (ER_NOT_ALLOWED_COMMAND)

Message: The used command is not allowed with this MySQL version

- Error: 1149 SQLSTATE: 42000 (ER_SYNTAX_ERROR)

Message: You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use

- Error: 1150 SQLSTATE: HY000 (ER_DELAYED_CANT_CHANGE_LOCK)

Message: Delayed insert thread couldn't get requested lock for table %s

- Error: 1151 SQLSTATE: HY000 (ER_TOO_MANY_DELAYED_THREADS)

Message: Too many delayed threads in use

- Error: 1152 SQLSTATE: 08S01 (ER_ABORTING_CONNECTION)
Message: Aborted connection %ld to db: '%s' user: '%s' (%s)
- Error: 1153 SQLSTATE: 08S01 (ER_NET_PACKET_TOO_LARGE)
Message: Got a packet bigger than 'max_allowed_packet' bytes
- Error: 1154 SQLSTATE: 08S01 (ER_NET_READ_ERROR_FROM_PIPE)
Message: Got a read error from the connection pipe
- Error: 1155 SQLSTATE: 08S01 (ER_NET_FCNTL_ERROR)
Message: Got an error from fcntl()
- Error: 1156 SQLSTATE: 08S01 (ER_NET_PACKETS_OUT_OF_ORDER)
Message: Got packets out of order
- Error: 1157 SQLSTATE: 08S01 (ER_NET_UNCOMPRESS_ERROR)
Message: Couldn't uncompress communication packet
- Error: 1158 SQLSTATE: 08S01 (ER_NET_READ_ERROR)
Message: Got an error reading communication packets
- Error: 1159 SQLSTATE: 08S01 (ER_NET_READ_INTERRUPTED)
Message: Got timeout reading communication packets
- Error: 1160 SQLSTATE: 08S01 (ER_NET_ERROR_ON_WRITE)
Message: Got an error writing communication packets
- Error: 1161 SQLSTATE: 08S01 (ER_NET_WRITE_INTERRUPTED)
Message: Got timeout writing communication packets
- Error: 1162 SQLSTATE: 42000 (ER_TOO_LONG_STRING)
Message: Result string is longer than 'max_allowed_packet' bytes
- Error: 1163 SQLSTATE: 42000 (ER_TABLE_CANT_HANDLE_BLOB)
Message: The used table type doesn't support BLOB/TEXT columns
- Error: 1164 SQLSTATE: 42000 (ER_TABLE_CANT_HANDLE_AUTO_INCREMENT)
Message: The used table type doesn't support AUTO_INCREMENT columns
- Error: 1165 SQLSTATE: HY000 (ER_DELAYED_INSERT_TABLE_LOCKED)
Message: INSERT DELAYED can't be used with table '%s' because it is locked with LOCK TABLES
- Error: 1166 SQLSTATE: 42000 (ER_WRONG_COLUMN_NAME)
Message: Incorrect column name '%s'
- Error: 1167 SQLSTATE: 42000 (ER_WRONG_KEY_COLUMN)
Message: The used storage engine can't index column '%s'

- Error: 1168 SQLSTATE: HY000 (ER_WRONG_MRG_TABLE)
Message: All tables in the MERGE table are not identically defined
- Error: 1169 SQLSTATE: 23000 (ER_DUP_UNIQUE)
Message: Can't write, because of unique constraint, to table '%s'
- Error: 1170 SQLSTATE: 42000 (ER_BLOB_KEY_WITHOUT_LENGTH)
Message: BLOB/TEXT column '%s' used in key specification without a key length
- Error: 1171 SQLSTATE: 42000 (ER_PRIMARY_CANT_HAVE_NULL)
Message: All parts of a PRIMARY KEY must be NOT NULL; if you need NULL in a key, use UNIQUE instead
- Error: 1172 SQLSTATE: 42000 (ER_TOO_MANY_ROWS)
Message: Result consisted of more than one row
- Error: 1173 SQLSTATE: 42000 (ER_REQUIRES_PRIMARY_KEY)
Message: This table type requires a primary key
- Error: 1174 SQLSTATE: HY000 (ER_NO_RAID_COMPILED)
Message: This version of MySQL is not compiled with RAID support
- Error: 1175 SQLSTATE: HY000 (ER_UPDATE_WITHOUT_KEY_IN_SAFE_MODE)
Message: You are using safe update mode and you tried to update a table without a WHERE that uses a KEY column
- Error: 1176 SQLSTATE: HY000 (ER_KEY_DOES_NOT_EXISTS)
Message: Key '%s' doesn't exist in table '%s'
- Error: 1177 SQLSTATE: 42000 (ER_CHECK_NO_SUCH_TABLE)
Message: Can't open table
- Error: 1178 SQLSTATE: 42000 (ER_CHECK_NOT_IMPLEMENTED)
Message: The storage engine for the table doesn't support %s
- Error: 1179 SQLSTATE: 25000 (ER_CANT_DO_THIS_DURING_AN_TRANSACTION)
Message: You are not allowed to execute this command in a transaction
- Error: 1180 SQLSTATE: HY000 (ER_ERROR_DURING_COMMIT)
Message: Got error %d during COMMIT
- Error: 1181 SQLSTATE: HY000 (ER_ERROR_DURING_ROLLBACK)
Message: Got error %d during ROLLBACK
- Error: 1182 SQLSTATE: HY000 (ER_ERROR_DURING_FLUSH_LOGS)
Message: Got error %d during FLUSH_LOGS
- Error: 1183 SQLSTATE: HY000 (ER_ERROR_DURING_CHECKPOINT)
Message: Got error %d during CHECKPOINT

- Error: 1184 SQLSTATE: 08S01 (ER_NEW_ABORTING_CONNECTION)
Message: Aborted connection %ld to db: '%s' user: '%s' host: '%s' (%s)
- Error: 1185 SQLSTATE: HY000 (ER_DUMP_NOT_IMPLEMENTED)
Message: The storage engine for the table does not support binary table dump
- Error: 1186 SQLSTATE: HY000 (ER_FLUSH_MASTER_BINLOG_CLOSED)
Message: Binlog closed, cannot RESET MASTER
- Error: 1187 SQLSTATE: HY000 (ER_INDEX_REBUILD)
Message: Failed rebuilding the index of dumped table '%s'
- Error: 1188 SQLSTATE: HY000 (ER_MASTER)
Message: Error from master: '%s'
- Error: 1189 SQLSTATE: 08S01 (ER_MASTER_NET_READ)
Message: Net error reading from master
- Error: 1190 SQLSTATE: 08S01 (ER_MASTER_NET_WRITE)
Message: Net error writing to master
- Error: 1191 SQLSTATE: HY000 (ER_FT_MATCHING_KEY_NOT_FOUND)
Message: Can't find FULLTEXT index matching the column list
- Error: 1192 SQLSTATE: HY000 (ER_LOCK_OR_ACTIVE_TRANSACTION)
Message: Can't execute the given command because you have active locked tables or an active transaction
- Error: 1193 SQLSTATE: HY000 (ER_UNKNOWN_SYSTEM_VARIABLE)
Message: Unknown system variable '%s'
- Error: 1194 SQLSTATE: HY000 (ER_CRASHED_ON_USAGE)
Message: Table '%s' is marked as crashed and should be repaired
- Error: 1195 SQLSTATE: HY000 (ER_CRASHED_ON_REPAIR)
Message: Table '%s' is marked as crashed and last (automatic?) repair failed
- Error: 1196 SQLSTATE: HY000 (ER_WARNING_NOT_COMPLETE_ROLLBACK)
Message: Some non-transactional changed tables couldn't be rolled back
- Error: 1197 SQLSTATE: HY000 (ER_TRANS_CACHE_FULL)
Message: Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage; increase this mysqld variable and try again
- Error: 1198 SQLSTATE: HY000 (ER_SLAVE_MUST_STOP)
Message: This operation cannot be performed with a running slave; run STOP SLAVE first
- Error: 1199 SQLSTATE: HY000 (ER_SLAVE_NOT_RUNNING)
Message: This operation requires a running slave; configure slave and do START SLAVE

- Error: 1200 SQLSTATE: HY000 (ER_BAD_SLAVE)
Message: The server is not configured as slave; fix in config file or with CHANGE MASTER TO
- Error: 1201 SQLSTATE: HY000 (ER_MASTER_INFO)
Message: Could not initialize master info structure; more error messages can be found in the MySQL error log
- Error: 1202 SQLSTATE: HY000 (ER_SLAVE_THREAD)
Message: Could not create slave thread; check system resources
- Error: 1203 SQLSTATE: 42000 (ER_TOO_MANY_USER_CONNECTIONS)
Message: User %s already has more than 'max_user_connections' active connections
- Error: 1204 SQLSTATE: HY000 (ER_SET_CONSTANTS_ONLY)
Message: You may only use constant expressions with SET
- Error: 1205 SQLSTATE: HY000 (ER_LOCK_WAIT_TIMEOUT)
Message: Lock wait timeout exceeded; try restarting transaction
- Error: 1206 SQLSTATE: HY000 (ER_LOCK_TABLE_FULL)
Message: The total number of locks exceeds the lock table size
- Error: 1207 SQLSTATE: 25000 (ER_READ_ONLY_TRANSACTION)
Message: Update locks cannot be acquired during a READ UNCOMMITTED transaction
- Error: 1208 SQLSTATE: HY000 (ER_DROP_DB_WITH_READ_LOCK)
Message: DROP DATABASE not allowed while thread is holding global read lock
- Error: 1209 SQLSTATE: HY000 (ER_CREATE_DB_WITH_READ_LOCK)
Message: CREATE DATABASE not allowed while thread is holding global read lock
- Error: 1210 SQLSTATE: HY000 (ER_WRONG_ARGUMENTS)
Message: Incorrect arguments to %s
- Error: 1211 SQLSTATE: 42000 (ER_NO_PERMISSION_TO_CREATE_USER)
Message: '%s'@'%s' is not allowed to create new users
- Error: 1212 SQLSTATE: HY000 (ER_UNION_TABLES_IN_DIFFERENT_DIR)
Message: Incorrect table definition; all MERGE tables must be in the same database
- Error: 1213 SQLSTATE: 40001 (ER_LOCK_DEADLOCK)
Message: Deadlock found when trying to get lock; try restarting transaction
- Error: 1214 SQLSTATE: HY000 (ER_TABLE_CANT_HANDLE_FT)
Message: The used table type doesn't support FULLTEXT indexes
- Error: 1215 SQLSTATE: HY000 (ER_CANNOT_ADD_FOREIGN)
Message: Cannot add foreign key constraint

- Error: 1216 SQLSTATE: 23000 (ER_NO_REFERENCED_ROW)
Message: Cannot add or update a child row: a foreign key constraint fails
- Error: 1217 SQLSTATE: 23000 (ER_ROW_IS_REFERENCED)
Message: Cannot delete or update a parent row: a foreign key constraint fails
- Error: 1218 SQLSTATE: 08S01 (ER_CONNECT_TO_MASTER)
Message: Error connecting to master: %s
- Error: 1219 SQLSTATE: HY000 (ER_QUERY_ON_MASTER)
Message: Error running query on master: %s
- Error: 1220 SQLSTATE: HY000 (ER_ERROR_WHEN_EXECUTING_COMMAND)
Message: Error when executing command %s: %s
- Error: 1221 SQLSTATE: HY000 (ER_WRONG_USAGE)
Message: Incorrect usage of %s and %s
- Error: 1222 SQLSTATE: 21000 (ER_WRONG_NUMBER_OF_COLUMNS_IN_SELECT)
Message: The used SELECT statements have a different number of columns
- Error: 1223 SQLSTATE: HY000 (ER_CANT_UPDATE_WITH_READLOCK)
Message: Can't execute the query because you have a conflicting read lock
- Error: 1224 SQLSTATE: HY000 (ER_MIXING_NOT_ALLOWED)
Message: Mixing of transactional and non-transactional tables is disabled
- Error: 1225 SQLSTATE: HY000 (ER_DUP_ARGUMENT)
Message: Option '%s' used twice in statement
- Error: 1226 SQLSTATE: 42000 (ER_USER_LIMIT_REACHED)
Message: User '%s' has exceeded the '%s' resource (current value: %ld)
- Error: 1227 SQLSTATE: 42000 (ER_SPECIFIC_ACCESS_DENIED_ERROR)
Message: Access denied; you need the %s privilege for this operation
- Error: 1228 SQLSTATE: HY000 (ER_LOCAL_VARIABLE)
Message: Variable '%s' is a SESSION variable and can't be used with SET GLOBAL
- Error: 1229 SQLSTATE: HY000 (ER_GLOBAL_VARIABLE)
Message: Variable '%s' is a GLOBAL variable and should be set with SET GLOBAL
- Error: 1230 SQLSTATE: 42000 (ER_NO_DEFAULT)
Message: Variable '%s' doesn't have a default value
- Error: 1231 SQLSTATE: 42000 (ER_WRONG_VALUE_FOR_VAR)
Message: Variable '%s' can't be set to the value of '%s'
- Error: 1232 SQLSTATE: 42000 (ER_WRONG_TYPE_FOR_VAR)

Message: Incorrect argument type to variable '%s'

- Error: 1233 SQLSTATE: HY000 (ER_VAR_CANT_BE_READ)

Message: Variable '%s' can only be set, not read

- Error: 1234 SQLSTATE: 42000 (ER_CANT_USE_OPTION_HERE)

Message: Incorrect usage/placement of '%s'

- Error: 1235 SQLSTATE: 42000 (ER_NOT_SUPPORTED_YET)

Message: This version of MySQL doesn't yet support '%s'

- Error: 1236 SQLSTATE: HY000 (ER_MASTER_FATAL_ERROR_READING_BINLOG)

Message: Got fatal error %d: '%s' from master when reading data from binary log

- Error: 1237 SQLSTATE: HY000 (ER_SLAVE_IGNORED_TABLE)

Message: Slave SQL thread ignored the query because of replicate-*-table rules

- Error: 1238 SQLSTATE: HY000 (ER_INCORRECT_GLOBAL_LOCAL_VAR)

Message: Variable '%s' is a %s variable

- Error: 1239 SQLSTATE: 42000 (ER_WRONG_FK_DEF)

Message: Incorrect foreign key definition for '%s': %s

- Error: 1240 SQLSTATE: HY000 (ER_KEY_REF_DO_NOT_MATCH_TABLE_REF)

Message: Key reference and table reference don't match

- Error: 1241 SQLSTATE: 21000 (ER_OPERAND_COLUMNS)

Message: Operand should contain %d column(s)

- Error: 1242 SQLSTATE: 21000 (ER_SUBQUERY_NO_1_ROW)

Message: Subquery returns more than 1 row

- Error: 1243 SQLSTATE: HY000 (ER_UNKNOWN_STMT_HANDLER)

Message: Unknown prepared statement handler (%.*s) given to %s

- Error: 1244 SQLSTATE: HY000 (ER_CORRUPT_HELP_DB)

Message: Help database is corrupt or does not exist

- Error: 1245 SQLSTATE: HY000 (ER_CYCLIC_REFERENCE)

Message: Cyclic reference on subqueries

- Error: 1246 SQLSTATE: HY000 (ER_AUTO_CONVERT)

Message: Converting column '%s' from %s to %s

- Error: 1247 SQLSTATE: 42S22 (ER_ILLEGAL_REFERENCE)

Message: Reference '%s' not supported (%s)

- Error: 1248 SQLSTATE: 42000 (ER_DERIVED_MUST_HAVE_ALIAS)

Message: Every derived table must have its own alias

- Error: 1249 SQLSTATE: 01000 (ER_SELECT_REDUCED)

Message: Select %u was reduced during optimization

- Error: 1250 SQLSTATE: 42000 (ER_TABLENAME_NOT_ALLOWED_HERE)

Message: Table '%s' from one of the SELECTs cannot be used in %s

- Error: 1251 SQLSTATE: 08004 (ER_NOT_SUPPORTED_AUTH_MODE)

Message: Client does not support authentication protocol requested by server; consider upgrading MySQL client

- Error: 1252 SQLSTATE: 42000 (ER_SPATIAL_CANT_HAVE_NULL)

Message: All parts of a SPATIAL index must be NOT NULL

- Error: 1253 SQLSTATE: 42000 (ER_COLLATION_CHARSET_MISMATCH)

Message: COLLATION '%s' is not valid for CHARACTER SET '%s'

- Error: 1254 SQLSTATE: HY000 (ER_SLAVE_WAS_RUNNING)

Message: Slave is already running

- Error: 1255 SQLSTATE: HY000 (ER_SLAVE_WAS_NOT_RUNNING)

Message: Slave already has been stopped

- Error: 1256 SQLSTATE: HY000 (ER_TOO_BIG_FOR_UNCOMPRESS)

Message: XAER_INVALID: Invalid arguments (or unsupported command)

- Error: 1399 SQLSTATE: XAE07 (ER_XAER_RMFAIL)

Message: XAER_RMFAIL: The command cannot be executed in the %s state

- Error: 1400 SQLSTATE: XAE09 (ER_XAER_OUTSIDE)

Message: XAER_OUTSIDE: Some work is done outside global transaction

- Error: 1401 SQLSTATE: XAE03 (ER_XAER_RMERR)

Message: XAER_RMERR: Fatal error occurred in the transaction branch - check your data for consistency

- Error: 1402 SQLSTATE: XA100 (ER_XA_RBROLLBACK)

Message: XA_RBROLLBACK: Transaction branch was rolled back

- Error: 1403 SQLSTATE: 42000 (ER_NONEXISTING_PROC_GRANT)

Message: There is no such grant defined for user '%s' on host '%s' on routine '%s'

- Error: 1404 SQLSTATE: HY000 (ER_PROC_AUTO_GRANT_FAIL)

Message: Failed to grant EXECUTE and ALTER ROUTINE privileges

- Error: 1405 SQLSTATE: HY000 (ER_PROC_AUTO_REVOKE_FAIL)

Message: Failed to revoke all privileges to dropped routine

- Error: 1406 SQLSTATE: 22001 (ER_DATA_TOO_LONG)

Message: Data too long for column '%s' at row %ld

- Error: 1407 SQLSTATE: 42000 (ER_SP_BAD_SQLSTATE)

Message: Bad SQLSTATE: '%s'

- Error: 1408 SQLSTATE: HY000 (ER_STARTUP)
Message: %s: ready for connections. Version: '%s' socket: '%s' port: %d %s
- Error: 1409 SQLSTATE: HY000 (ER_LOAD_FROM_FIXED_SIZE_ROWS_TO_VAR)
Message: Can't load value from file with fixed size rows to variable
- Error: 1410 SQLSTATE: 42000 (ER_CANT_CREATE_USER_WITH_GRANT)
Message: You are not allowed to create a user with GRANT
- Error: 1411 SQLSTATE: HY000 (ER_WRONG_VALUE_FOR_TYPE)
Message: Incorrect %s value: '%s' for function %s
- Error: 1412 SQLSTATE: HY000 (ER_TABLE_DEF_CHANGED)
Message: Table definition has changed, please retry transaction
- Error: 1413 SQLSTATE: 42000 (ER_SP_DUP_HANDLER)
Message: Duplicate handler declared in the same block

Client error information comes from the following files:

- The Error values and the symbols in parentheses correspond to definitions in the `include/er-rmsg.h` MySQL source file.
- The Message values correspond to the error messages that are listed in the `libmysql/er-rmsg.c` file. %d or %s represent numbers or strings that are substituted into the messages % when they are displayed.

Because updates are frequent, it is possible that these files contain additional error information not listed here.

- Error: 2000 (CR_UNKNOWN_ERROR)
Message: Unknown MySQL error
- Error: 2001 (CR_SOCKET_CREATE_ERROR)
Message: Can't create UNIX socket (%d)
- Error: 2002 (CR_CONNECTION_ERROR)
Message: Can't connect to local MySQL server through socket '%s' (%d)
- Error: 2003 (CR_CONN_HOST_ERROR)
Message: Can't connect to MySQL server on '%s' (%d)
- Error: 2004 (CR_IPSOCK_ERROR)
Message: Can't create TCP/IP socket (%d)
- Error: 2005 (CR_UNKNOWN_HOST)

- Message: Unknown MySQL server host '%s' (%d)
- Error: 2006 (CR_SERVER_GONE_ERROR)
Message: MySQL server has gone away
- Error: 2007 (CR_VERSION_ERROR)
Message: Protocol mismatch; server version = %d, client version = %d
- Error: 2008 (CR_OUT_OF_MEMORY)
Message: MySQL client ran out of memory
- Error: 2009 (CR_WRONG_HOST_INFO)
Message: Wrong host info
- Error: 2010 (CR_LOCALHOST_CONNECTION)
Message: Localhost via UNIX socket
- Error: 2011 (CR_TCP_CONNECTION)
Message: %s via TCP/IP
- Error: 2012 (CR_SERVER_HANDSHAKE_ERR)
Message: Error in server handshake
- Error: 2013 (CR_SERVER_LOST)
Message: Lost connection to MySQL server during query
- Error: 2014 (CR_COMMANDS_OUT_OF_SYNC)
Message: Commands out of sync; you can't run this command now
- Error: 2015 (CR_NAMEDPIPE_CONNECTION)
Message: Named pipe: %s
- Error: 2016 (CR_NAMEDPIPEWAIT_ERROR)
Message: Can't wait for named pipe to host: %s pipe: %s (%lu)
- Error: 2017 (CR_NAMEDPIPEOPEN_ERROR)
Message: Can't open named pipe to host: %s pipe: %s (%lu)
- Error: 2018 (CR_NAMEDPIPESETSTATE_ERROR)
Message: Can't set state of named pipe to host: %s pipe: %s (%lu)
- Error: 2019 (CR_CANT_READ_CHARSET)
Message: Can't initialize character set %s (path: %s)
- Error: 2020 (CR_NET_PACKET_TOO_LARGE)
Message: Got packet bigger than 'max_allowed_packet' bytes
- Error: 2021 (CR_EMBEDDED_CONNECTION)

Message: Embedded server

- Error: 2022 (CR_PROBE_SLAVE_STATUS)

Message: Error on SHOW SLAVE STATUS:

- Error: 2023 (CR_PROBE_SLAVE_HOSTS)

Message: Error on SHOW SLAVE HOSTS:

- Error: 2024 (CR_PROBE_SLAVE_CONNECT)

Message: Error connecting to slave:

- Error: 2025 (CR_PROBE_MASTER_CONNECT)

Message: Error connecting to master:

- Error: 2026 (CR_SSL_CONNECTION_ERROR)

Message: SSL connection error

- Error: 2027 (CR_MALFORMED_PACKET)

Message: Malformed packet

- Error: 2028 (CR_WRONG_LICENSE)

Message: This client library is licensed only for use with MySQL servers having '%s' license

- Error: 2029 (CR_NULL_POINTER)

Message: Invalid use of null pointer

- Error: 2030 (CR_NO_PREPARE_STMT)

Message: Statement not prepared

- Error: 2031 (CR_PARAMS_NOT_BOUND)

Message: No data supplied for parameters in prepared statement

- Error: 2032 (CR_DATA_TRUNCATED)

Message: Data truncated

- Error: 2033 (CR_NO_PARAMETERS_EXISTS)

Message: No parameters exist in the statement

Chapter 27. Extending MySQL

27.1. MySQL Internals

This chapter describes a lot of things that you need to know when working on the MySQL code. If you plan to contribute to MySQL development, want to have access to the bleeding-edge in-between versions code, or just want to keep track of development, follow the instructions in Section 2.8.3, “Installing from the Development Source Tree”. If you are interested in MySQL internals, you should also subscribe to our `internals` mailing list. This list is relatively low traffic. For details on how to subscribe, please see Section 1.6.1.1, “The MySQL Mailing Lists”. All developers at MySQL AB are on the `internals` list and we help other people who are working on the MySQL code. Feel free to use this list both to ask questions about the code and to send patches that you would like to contribute to the MySQL project!

27.1.1. MySQL Threads

The MySQL server creates the following threads:

- The TCP/IP connection thread handles all connection requests and creates a new dedicated thread to handle the authentication and SQL query processing for each connection.
- On Windows NT there is a named pipe handler thread that does the same work as the TCP/IP connection thread on named pipe connect requests.
- The signal thread handles all signals. This thread also normally handles alarms and calls `process_alarm()` to force timeouts on connections that have been idle too long.
- If `mysqld` is compiled with `-DUSE_ALARM_THREAD`, a dedicated thread that handles alarms is created. This is only used on some systems where there are problems with `sigwait()` or if you want to use the `thr_alarm()` code in your application without a dedicated signal handling thread.
- If one uses the `--flush_time=#` option, a dedicated thread is created to flush all tables at the given interval.
- Every connection has its own thread.
- Every different table on which one uses `INSERT DELAYED` gets its own thread.
- If you use `--master-host`, a slave replication thread is started to read and apply updates from the master.

`mysqladmin processlist` only shows the connection, `INSERT DELAYED`, and replication threads.

27.1.2. MySQL Test Suite

Until recently, our main full-coverage test suite was based on proprietary customer data and for that reason has not been publicly available. The only publicly available part of our testing process consisted of the `crash-me` test, a Perl DBI/DBD benchmark found in the `sql-bench` directory, and miscellaneous tests located in `tests` directory. The lack of a standardized publicly available test suite has made it difficult for our users, as well developers, to do regression tests on the MySQL code. To address this problem, we have created a new test system that is included in Unix source distributions and binary distributions starting with Version 3.23.29. The tests can be run under Unix, or on Windows in the Cygwin environment if the server has been compiled under Cygwin. They cannot be run in a native Windows environment currently.

The current set of test cases doesn't test everything in MySQL, but it should catch most obvious

bugs in the SQL processing code, OS/library issues, and is quite thorough in testing replication. Our eventual goal is to have the tests cover 100% of the code. We welcome contributions to our test suite. You may especially want to contribute tests that examine the functionality critical to your system, because this ensures that all future MySQL releases work well with your applications.

27.1.2.1. Running the MySQL Test Suite

The test system consist of a test language interpreter (**mysqltest**), a shell script to run all tests(**mysql-test-run**), the actual test cases written in a special test language, and their expected results. To run the test suite on your system after a build, type **make test** or **mysql-test/mysql-test-run** from the source root. If you have installed a binary distribution, **cd** to the install root (eg. **/usr/local/mysql**), and do **scripts/mysql-test-run**. All tests should succeed. If not, you should try to find out why and report the problem if this is a bug in MySQL. See Section 27.1.2.3, “Reporting Bugs in the MySQL Test Suite”.

From MySQL 4.1 on, if you have a copy of **mysqld** running on the machine where you want to run the test suite you do not have to stop it, as long as it is not using ports 9306 and 9307. If one of those ports is taken, you should edit **mysql-test-run** and change the values of the master and/or slave port to one that is available.

Before MySQL 4.1, **mysql-test-run** does not try to run its own server by default but tries to use your currently running server. To override this and cause **mysql-test-run** to start its own server, run it with the **--local** option.

You can run one individual test case with **mysql-test/mysql-test-run test_name**.

If one test fails, you should test running **mysql-test-run** with the **--force** option to check whether any other tests fail.

27.1.2.2. Extending the MySQL Test Suite

You can use the **mysqltest** language to write your own test cases. Unfortunately, we have not yet written full documentation for it. You can, however, look at our current test cases and use them as an example. The following points should help you get started:

- The tests are located in **mysql-test/t/*.test**
- A test case consists of **;** terminated statements and is similar to the input of **mysql** command-line client. A statement by default is a query to be sent to MySQL server, unless it is recognized as internal command (eg. **sleep**).
- All queries that produce results---for example, **SELECT**, **SHOW**, **EXPLAIN**, etc., must be preceded with **@/path/to/result/file**. The file must contain the expected results. An easy way to generate the result file is to run **mysqltest -r < t/test-case-name.test** from the **mysql-test** directory, and then edit the generated result files, if needed, to adjust them to the expected output. In that case, be very careful about not adding or deleting any invisible characters --- make sure to only change the text and/or delete lines. If you have to insert a line, make sure that the fields are separated by a hard tab, and that there is a hard tab at the end. You may want to use **od -c** to make sure that your text editor has not messed anything up during edit. We hope that you never have to edit the output of **mysqltest -r** as you only have to do it when you find a bug.
- To be consistent with our setup, you should put your result files in the **mysql-test/r** directory and name them **test_name.result**. If the test produces more than one result, you should use **test_name.a.result**, **test_name.b.result**, etc.
- If a statement returns an error, you should specify it with **--error error-number** on the line before the statement. The error number can be a list of possible error numbers separated by **','**.
- If you are writing a replication test case, you should on the first line of the test file, put **source include/master-slave.inc;**. To switch between master and slave, use **connection**

master; and connection slave;. If you need to do something on an alternate connection, you can do connection master1; for the master, and connection slave1; for the slave.

- If you need to do something in a loop, you can use something like this:

```
let $1=1000;
while ($1)
{
  # do your queries here
  dec $1;
}
```

- To sleep between queries, use the **sleep** command. It supports fractions of a second, so you can use **sleep 1.3**;, for example, to sleep 1.3 seconds.
- To run the slave with additional options for your test case, put them in the command-line format in `mysql-test/t/test_name-slave.opt`. For the master, put them in `mysql-test/t/test_name-master.opt`.
- If you have a question about the test suite, or have a test case to contribute, send an email message to the MySQL `internals` mailing list. See Section 1.6.1.1, “The MySQL Mailing Lists”. As this list does not accept attachments, you should ftp all the relevant files to: `ftp://ftp.mysql.com/pub/mysql/upload/`

27.1.2.3. Reporting Bugs in the MySQL Test Suite

If your MySQL version doesn't pass the test suite you should do the following:

- Don't send a bug report before you have found out as much as possible of what when wrong! When you do it, please use the **mysqlbug** script so that we can get information about your system and MySQL version. See Section 1.6.1.3, “How to Report Bugs or Problems”.
- Make sure to include the output of **mysql-test-run**, as well as contents of all `.reject` files in `mysql-test/r` directory.
- If a test in the test suite fails, check whether the test fails also when run by its own:

```
cd mysql-test
mysql-test-run --local test-name
```

If this fails, then you should configure MySQL with `--with-debug` and run **mysql-test-run** with the `--debug` option. If this also fails send the trace file `var/tmp/master.trace` to `ftp://ftp.mysql.com/pub/mysql/upload/` so that we can examine it. Please remember to also include a full description of your system, the version of the **mysqld** binary and how you compiled it.

- Try also to run **mysql-test-run** with the `--force` option to see whether there is any other test that fails.
- If you have compiled MySQL yourself, check our manual for how to compile MySQL on your platform or, preferable, use one of the binaries we have compiled for you at `http://dev.mysql.com/downloads/`. All our standard binaries should pass the test suite!
- If you get an error such as `Result length mismatch` or `Result content mismatch` it means that the output of the test didn't match exactly the expected output. This could be a bug in MySQL or that your version of **mysqld** produces slightly different results under some circumstances.

Failed test results are put in a file with the same base name as the result file with the `.reject`

extension. If your test case is failing, you should do a diff on the two files. If you cannot see how they are different, examine both with `od -c` and also check their lengths.

- If a test fails totally, you should check the logs file in the `mysql-test/var/log` directory for hints of what went wrong.
- If you have compiled MySQL with debugging you can try to debug this by running **mysql-test-run** with the `--gdb` and/or `--debug` options. See Section E.1.2, “Creating Trace Files”.

If you have not compiled MySQL for debugging you should probably do that. Just specify the `--with-debug` options to **configure**. See Section 2.8, “MySQL Installation Using a Source Distribution”.

27.2. Adding New Functions to MySQL

There are two ways to add new functions to MySQL:

- You can add functions through the user-defined function (UDF) interface. User-defined functions are compiled as object files and then added to and removed from the server dynamically using the `CREATE FUNCTION` and `DROP FUNCTION` statements. See Section 27.2.2, “CREATE FUNCTION/DROP FUNCTION Syntax”.
- You can add functions as native (built-in) MySQL functions. Native functions are compiled into the **mysqld** server and become available on a permanent basis.

Each method has advantages and disadvantages:

- If you write user-defined functions, you must install object files in addition to the server itself. If you compile your function into the server, you don't need to do that.
- You can add UDFs to a binary MySQL distribution. Native functions require you to modify a source distribution.
- If you upgrade your MySQL distribution, you can continue to use your previously installed UDFs, unless you upgrade to a newer version for which the UDF interface changes. (An incompatible change occurred in MySQL 4.1.1 for aggregate functions. A function named `xxx_clear()` must be defined rather than `xxx_reset()`.) For native functions, you must repeat your modifications each time you upgrade.

Whichever method you use to add new functions, they can be invoked in SQL statements just like native functions such as `ABS()` or `SOUNDEX()`.

Another way to add functions is by creating stored functions. These are written using SQL statements rather than by compiling object code. The syntax for writing stored functions is described in *Stored Procedures*.

The following sections describe features of the UDF interface, provide instructions for writing UDFs, and discuss security precautions that MySQL takes to prevent UDF misuse.

For example source code that illustrates how to write UDFs, take a look at the `sql/udf_example.cc` file that is provided in MySQL source distributions.

27.2.1. Features of the User-Defined Function Interface

The MySQL interface for user-defined functions provides the following features and capabilities:

- Functions can return string, integer, or real values.
- You can define simple functions that operate on a single row at a time, or aggregate functions that operate on groups of rows.
- Information is provided to functions that enables them to check the number and types of the arguments passed to them.
- You can tell MySQL to coerce arguments to a given type before passing them to a function.
- You can indicate that a function returns NULL or that an error occurred.

27.2.2. CREATE FUNCTION/DROP FUNCTION Syntax

```
CREATE [AGGREGATE] FUNCTION function_name RETURNS {STRING|INTEGER|REAL}
        SONAME shared_library_name
```

```
DROP FUNCTION function_name
```

A user-defined function (UDF) is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`.

function_name is the name that should be used in SQL statements to invoke the function. The RETURNS clause indicates the type of the function's return value. *shared_library_name* is the basename of the shared object file that contains the code that implements the function. The file must be located in a directory that is searched by your system's dynamic linker.

To create a function, you must have the INSERT and privilege for the `mysql` database. To drop a function, you must have the DELETE privilege for the `mysql` database. This is because CREATE FUNCTION adds a row to the `mysql.func` system table that records the function's name, type, and shared library name, and DROP FUNCTION deletes the function's row from that table. If you do not have this table, you should run the `mysql_fix_privilege_tables` script to create it. See Section 2.10.7, “Upgrading the Grant Tables”.

An active function is one that has been loaded with CREATE FUNCTION and not removed with DROP FUNCTION. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

For instructions on writing user-defined functions, see Section 27.2.3, “Adding a New User-defined Function”. For the UDF mechanism to work, functions must be written in C or C++, your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

AGGREGATE is a new option for MySQL 3.23. An AGGREGATE function works exactly like a native MySQL aggregate (summary) function such as `SUM` or `COUNT()`. For AGGREGATE to work, your `mysql.func` table must contain a `type` column. If your `mysql.func` table does not have this column, you should run the `mysql_fix_privilege_tables` script to create it.

27.2.3. Adding a New User-defined Function

For the UDF mechanism to work, functions must be written in C or C++ and your operating system must support dynamic loading. The MySQL source distribution includes a file `sql/udf_example.cc` that defines 5 new functions. Consult this file to see how UDF calling conventions work.

To be able to use UDFs, you need to link `mysqld` dynamically. Don't configure MySQL using `--with-mysqld-ldflags=-all-static`. If you want to use a UDF that needs to access symbols from `mysqld` (for example, the `metaphone` function in `sql/udf_example.cc` that uses `default_charset_info`), you must link the program with `-rdynamic` (see `man dlopen`).

If you plan to use UDFs, the rule of thumb is to configure MySQL with `--with-mysqld-ldflags=-rdynamic` unless you have a very good reason not to.

If you to use a precompiled distribution of MySQL, use MySQL-Max, which contains a dynamically linked server that supports dynamic loading.

For each function that you want to use in SQL statements, you should define corresponding C (or C++) functions. In the following discussion, the name `xxx` is used for an example function name. To distinguish between SQL and C/C++ usage, `XXX()` (uppercase) indicates an SQL function call, and `xxx()` (lowercase) indicates a C/C++ function call.

The C/C++ functions that you write to implement the interface for `XXX()` are:

- `xxx()` (required)

The main function. This is where the function result is computed. The correspondence between the SQL function data type and the return type of your C/C++ function is shown here:

SQL Type	C/C++ Type
STRING	char *
INTEGER	long long
REAL	double

- `xxx_init()` (optional)

The initialization function for `xxx()`. It can be used to:

- Check the number of arguments to `XXX()`.
- Check that the arguments are of a required type or, alternatively, tell MySQL to coerce arguments to the types you want when the main function is called.
- Allocate any memory required by the main function.
- Specify the maximum length of the result.
- Specify (for REAL functions) the maximum number of decimals.
- Specify whether the result can be NULL.
- `xxx_deinit()` (optional)

The deinitialization function for `xxx()`. It should deallocate any memory allocated by the initialization function.

When an SQL statement invokes `XXX()`, MySQL calls the initialization function `xxx_init()` to let it perform any required setup, such as argument checking or memory allocation. If `xxx_init()` returns an error, the SQL statement is aborted with an error message and the main and deinitialization functions are not called. Otherwise, the main function `xxx()` is called once for each row. After all rows have been processed, the deinitialization function `xxx_deinit()` is called so it can perform any required cleanup.

For aggregate functions that work like `SUM()`, you must also provide the following functions:

- `xxx_reset()` (required before 4.1.1)

Reset the current aggregate value and insert the argument as the initial aggregate value for a new group.

- `xxx_clear()` (required starting from 4.1.1)

Reset the current aggregate value but do not insert the argument as the initial aggregate value for a new group.

- `xxx_add()` (required)

Add the argument to the current aggregate value.

MySQL handles aggregate UDFs as follows:

1. Call `xxx_init()` to let the aggregate function allocate any memory it needs for storing results.
2. Sort the table according to the `GROUP BY` expression.
3. Call `xxx_clear()` for the first row in each new group.
4. Call `xxx_add()` for each new row that belongs in the same group.
5. Call `xxx()` to get the result for the aggregate when the group changes or after the last row has been processed.
6. Repeat 3-5 until all rows has been processed
7. Call `xxx_deinit()` to let the UDF free any memory it has allocated.

All functions must be thread-safe. This includes not just the main function, but the initialization and deinitialization functions as well, and also the additional functions required by aggregate functions. A consequence of this requirement is that you are not allowed to allocate any global or static variables that change! If you need memory, you should allocate it in `xxx_init()` and free it in `xxx_deinit()`.

27.2.3.1. UDF Calling Sequences for simple functions

This section describes the different functions that you need to define when you create a simple UDF. Section 27.2.3, “Adding a New User-defined Function” describes the order in which MySQL calls these functions.

The main `xxx()` function should be declared as shown in this section. Note that the return type and parameters differ, depending on whether you declare the SQL function `XXX()` to return `STRING`, `INTEGER`, or `REAL` in the `CREATE FUNCTION` statement:

For `STRING` functions:

```
char *xxx(UDF_INIT *initid, UDF_ARGS *args,
          char *result, unsigned long *length,
          char *is_null, char *error);
```

For `INTEGER` functions:

```
long long xxx(UDF_INIT *initid, UDF_ARGS *args,
              char *is_null, char *error);
```

For `REAL` functions:

```
double xxx(UDF_INIT *initid, UDF_ARGS *args,
           char *is_null, char *error);
```

The initialization and deinitialization functions are declared like this:

```
my_bool xxx_init(UDF_INIT *initid, UDF_ARGS *args, char *message);
void xxx_deinit(UDF_INIT *initid);
```

The `initid` parameter is passed to all three functions. It points to a `UDF_INIT` structure that is used to communicate information between functions. The `UDF_INIT` structure members follow. The initialization function should fill in any members that it wishes to change. (To use the default for a member, leave it unchanged.)

- `my_bool maybe_null`

`xxx_init()` should set `maybe_null` to 1 if `xxx()` can return `NULL`. The default value is 1 if any of the arguments are declared `maybe_null`.

- `unsigned int decimals`

The number of decimals. The default value is the maximum number of decimals in the arguments passed to the main function. (For example, if the function is passed `1.34`, `1.345`, and `1.3`, the default would be 3, because `1.345` has 3 decimals.)

- `unsigned int max_length`

The maximum length of the result. The default `max_length` value differs depending on the result type of the function. For string functions, the default is the length of the longest argument. For integer functions, the default is 21 digits. For real functions, the default is 13 plus the number of decimals indicated by `initid->decimals`. (For numeric functions, the length includes any sign or decimal point characters.)

If you want to return a blob value, you can set `max_length` to 65KB or 16MB. This memory is not allocated, but the value is used to decide which column type to use if there is a need to temporarily store the data.

- `char *ptr`

A pointer that the function can use for its own purposes. For example, functions can use `initid->ptr` to communicate allocated memory among themselves. `xxx_init()` should allocate the memory and assign it to this pointer:

```
initid->ptr = allocated_memory;
```

In `xxx()` and `xxx_deinit()`, refer to `initid->ptr` to use or deallocate the memory.

27.2.3.2. UDF Calling Sequences for aggregate functions

This section describes the different functions that you need to define when you create an aggregate UDF. Section 27.2.3, “Adding a New User-defined Function” describes the order in which MySQL calls these functions.

- `xxx_reset()`

This function is called when MySQL finds the first row in a new group. It should reset any internal summary variables and then use the given `UDF_ARGS` argument as the first value in your internal summary value for the group. Declare `xxx_reset()` as follows:

```
char *xxx_reset(UDF_INIT *initid, UDF_ARGS *args,
```

```
char *is_null, char *error);
```

`xxx_reset()` is needed only before MySQL 4.1.1. It is *not* needed or used as of MySQL 4.1.1, when the UDF interface changed to use `xxx_clear()` instead. However, you can define both `xxx_reset()` and `xxx_clear()` if you want to have your UDF work both before and after the interface change. (If you do include both functions, the `xxx_reset()` function in many cases can be implemented internally by calling `xxx_clear()` to reset all variables, and then calling `xxx_add()` to add the `UDF_ARGS` argument as the first value in the group.)

- `xxx_clear()`

This function is called when MySQL needs to reset the summary results. It is called at the beginning for each new group but can also be called to reset the values for a query where there were no matching rows. Declare `xxx_clear()` as follows:

```
char *xxx_clear(UDF_INIT *initid, char *is_null, char *error);
```

`is_null` is set to point to `CHAR(0)` before calling `xxx_clear()`.

If something went wrong, you can store a value in the variable to which the `error` argument points. `error` points to a single-byte variable, not to a string buffer.

`xxx_clear()` is required only by MySQL 4.1.1 and above. Before MySQL 4.1.1, use `xxx_reset()` instead.

- `xxx_add()`

This function is called for all rows that belong to the same group, except for the first row. You should use it to add the value in the `UDF_ARGS` argument to your internal summary variable.

```
char *xxx_add(UDF_INIT *initid, UDF_ARGS *args,
             char *is_null, char *error);
```

The `xxx()` function for an aggregate UDF should be declared the same way as for a non-aggregate UDF. See Section 27.2.3.1, “UDF Calling Sequences for simple functions”.

For an aggregate UDF, MySQL calls the `xxx()` function after all rows in the group have been processed. You should normally never access its `UDF_ARGS` argument here but instead return a value based on your internal summary variables.

Return value handling in `xxx()` should be done the same way as for a non-aggregate UDF. See Section 27.2.3.4, “Return Values and Error Handling”.

The `xxx_reset()` and `xxx_add()` functions handle their `UDF_ARGS` argument the same way as functions for non-aggregate UDFs. See Section 27.2.3.3, “Argument Processing”.

The pointer arguments to `is_null` and `error` are the same for all calls to `xxx_reset()`, `xxx_clear()`, `xxx_add()` and `xxx()`. You can use this to remember that you got an error or whether the `xxx()` function should return `NULL`. You should not store a string into `*error`! `error` points to a single-byte variable, not to a string buffer.

`*is_null` is reset for each group (before calling `xxx_clear()`). `*error` is never reset.

If `*is_null` or `*error` are set when `xxx()` returns, MySQL returns `NULL` as the result for the group function.

27.2.3.3. Argument Processing

The `args` parameter points to a `UDF_ARGS` structure that has the members listed here:

- `unsigned int arg_count`

The number of arguments. Check this value in the initialization function if you require your function to be called with a particular number of arguments. For example:

```
if (args->arg_count != 2)
{
    strcpy(message, "XXX() requires two arguments");
    return 1;
}
```

- `enum Item_result *arg_type`

A pointer to an array containing the types for each argument. The possible type values are `STRING_RESULT`, `INT_RESULT`, and `REAL_RESULT`.

To make sure that arguments are of a given type and return an error if they are not, check the `arg_type` array in the initialization function. For example:

```
if (args->arg_type[0] != STRING_RESULT ||
    args->arg_type[1] != INT_RESULT)
{
    strcpy(message, "XXX() requires a string and an integer");
    return 1;
}
```

As an alternative to requiring your function's arguments to be of particular types, you can use the initialization function to set the `arg_type` elements to the types you want. This causes MySQL to coerce arguments to those types for each call to `xxx()`. For example, to specify that the first two arguments should be coerced to string and integer, respectively, do this in `xxx_init()`:

```
args->arg_type[0] = STRING_RESULT;
args->arg_type[1] = INT_RESULT;
```

- `char **args`

`args->args` communicates information to the initialization function about the general nature of the arguments passed to your function. For a constant argument `i`, `args->args[i]` points to the argument value. (See below for instructions on how to access the value properly.) For a non-constant argument, `args->args[i]` is 0. A constant argument is an expression that uses only constants, such as 3 or $4*7-2$ or $\text{SIN}(3.14)$. A non-constant argument is an expression that refers to values that may change from row to row, such as column names or functions that are called with non-constant arguments.

For each invocation of the main function, `args->args` contains the actual arguments that are passed for the row currently being processed.

Functions can refer to an argument `i` as follows:

- An argument of type `STRING_RESULT` is given as a string pointer plus a length, to allow handling of binary data or data of arbitrary length. The string contents are available as `args->args[i]` and the string length is `args->lengths[i]`. You should not assume that strings are null-terminated.
- For an argument of type `INT_RESULT`, you must cast `args->args[i]` to a long

long value:

```
long long int_val;
int_val = *((long long*) args->args[i]);
```

- For an argument of type REAL_RESULT, you must cast args->args[i] to a double value:

```
double    real_val;
real_val = *((double*) args->args[i]);
```

- unsigned long *lengths

For the initialization function, the lengths array indicates the maximum string length for each argument. You should not change these. For each invocation of the main function, lengths contains the actual lengths of any string arguments that are passed for the row currently being processed. For arguments of types INT_RESULT or REAL_RESULT, lengths still contains the maximum length of the argument (as for the initialization function).

27.2.3.4. Return Values and Error Handling

The initialization function should return 0 if no error occurred and 1 otherwise. If an error occurs, xxx_init() should store a null-terminated error message in the message parameter. The message is returned to the client. The message buffer is MYSQL_ERRMSG_SIZE characters long, but you should try to keep the message to less than 80 characters so that it fits the width of a standard terminal screen.

The return value of the main function xxx() is the function value, for long long and double functions. A string function should return a pointer to the result and set *result and *length to the contents and length of the return value. For example:

```
memcpy(result, "result string", 13);
*length = 13;
```

The result buffer that is passed to the xxx() function is 255 bytes long. If your result fits in this, you don't have to worry about memory allocation for results.

If your string function needs to return a string longer than 255 bytes, you must allocate the space for it with malloc() in your xxx_init() function or your xxx() function and free it in your xxx_deinit() function. You can store the allocated memory in the ptr slot in the UDF_INIT structure for reuse by future xxx() calls. See Section 27.2.3.1, "UDF Calling Sequences for simple functions".

To indicate a return value of NULL in the main function, set *is_null to 1:

```
*is_null = 1;
```

To indicate an error return in the main function, set *error to 1:

```
*error = 1;
```

If xxx() sets *error to 1 for any row, the function value is NULL for the current row and for any subsequent rows processed by the statement in which xxx() was invoked. (xxx() is not even called for subsequent rows.) **Note:** Before MySQL 3.22.10, you should set both *error and *is_null:

```
*error = 1;
*is_null = 1;
```

27.2.3.5. Compiling and Installing User-defined Functions

Files implementing UDFs must be compiled and installed on the host where the server runs. This process is described below for the example UDF file `sql/udf_example.cc` that is included in the MySQL source distribution.

The immediately following instructions are for Unix. Instructions for Windows are given later in this section.

The `udf_example.cc` file contains the following functions:

- `metaphon()` returns a metaphon string of the string argument. This is something like a soundex string, but it's more tuned for English.
- `myfunc_double()` returns the sum of the ASCII values of the characters in its arguments, divided by the sum of the length of its arguments.
- `myfunc_int()` returns the sum of the length of its arguments.
- `sequence([const int])` returns a sequence starting from the given number or 1 if no number has been given.
- `lookup()` returns the IP number for a hostname.
- `reverse_lookup()` returns the hostname for an IP number. The function may be called either with a single string argument of the form `'xxx.xxx.xxx.xxx'` or with four numbers.

A dynamically loadable file should be compiled as a sharable object file, using a command something like this:

```
shell> gcc -shared -o udf_example.so udf_example.cc
```

If you are using **gcc**, you should be able to create `udf_example.so` with a simpler command:

```
shell> make udf_example.so
```

You can easily determine the correct compiler options for your system by running this command in the `sql` directory of your MySQL source tree:

```
shell> make udf_example.o
```

You should run a compile command similar to the one that **make** displays, except that you should remove the `-c` option near the end of the line and add `-o udf_example.so` to the end of the line. (On some systems, you may need to leave the `-c` on the command.)

After you compile a shared object containing UDFs, you must install it and tell MySQL about it. Compiling a shared object from `udf_example.cc` produces a file named something like `udf_example.so` (the exact name may vary from platform to platform). Copy this file to some directory such as `/usr/lib` that searched by your system's dynamic (runtime) linker, or add the directory in which you placed the shared object to the linker configuration file (for example, `/etc/ld.so.conf`).

The dynamic linker name is system-specific (for example, **ld-elf.so.1** on FreeBSD, **ld.so** on Linux, or **dyld** on Mac OS X). Consult your system documentation for information about the linker name and how to configure it.

On many systems, you can also set the `LD_LIBRARY` or `LD_LIBRARY_PATH` environment vari-

able to point at the directory where you have the files for your UDF. The `dlopen` manual page tells you which variable you should use on your system. You should set this in **mysql.server** or **mysqld_safe** startup scripts and restart **mysqld**.

On some systems, the **ldconfig** program that configures the dynamic linker does not recognize a shared object unless its name begins with `lib`. In this case you should rename a file such as `udf_example.so` to `libudf_example.so`.

On Windows, you can compile user-defined functions by using the following procedure:

1. You need to obtain the BitKeeper source repository for MySQL 4.0 or higher. See Section 2.8.3, “Installing from the Development Source Tree”.
2. In the source repository, look in the `VC++Files/examples/udf_example` directory. There are files named `udf_example.def`, `udf_example.dsp`, and `udf_example.dsw` there.
3. In the source repository, look in the `sql` directory. Copy the `udf_example.cc` from this directory to the `VC++Files/examples/udf_example` directory and rename the file to `udf_example.cpp`.
4. Open the `udf_example.dsw` file with Visual Studio VC++ and use it to compile the UDFs as a normal project.

After the shared object file has been installed, notify **mysqld** about the new functions with these statements:

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_double RETURNS REAL SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_int RETURNS INTEGER SONAME 'udf_example.so';
mysql> CREATE FUNCTION lookup RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION reverse_lookup
-> RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE AGGREGATE FUNCTION avgcost
-> RETURNS REAL SONAME 'udf_example.so';
```

Functions can be deleted using `DROP FUNCTION`:

```
mysql> DROP FUNCTION metaphon;
mysql> DROP FUNCTION myfunc_double;
mysql> DROP FUNCTION myfunc_int;
mysql> DROP FUNCTION lookup;
mysql> DROP FUNCTION reverse_lookup;
mysql> DROP FUNCTION avgcost;
```

The `CREATE FUNCTION` and `DROP FUNCTION` statements update the `func` system table in the `mysql` database. The function's name, type and shared library name are saved in the table. You must have the `INSERT` and `DELETE` privileges for the `mysql` database to create and drop functions.

You should not use `CREATE FUNCTION` to add a function that has previously been created. If you need to reinstall a function, you should remove it with `DROP FUNCTION` and then reinstall it with `CREATE FUNCTION`. You would need to do this, for example, if you recompile a new version of your function, so that **mysqld** gets the new version. Otherwise, the server continues to use the old version.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start **mysqld** with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

27.2.3.6. User-defined Function Security Precautions

MySQL takes the following measures to prevent misuse of user-defined functions.

You must have the `INSERT` privilege to be able to use `CREATE FUNCTION` and the `DELETE` privilege to be able to use `DROP FUNCTION`. This is necessary because these statements add and delete rows from the `mysql.func` table.

UDFs should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`, `xxx_deinit()`, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` functions. As of MySQL 4.0.24, 4.1.10a, and 5.0.3, **mysqld** supports an `--allow-suspicious-udfs` option that controls whether UDFs that have only an `xxx` symbol can be loaded. By default, the option is off, to prevent attempts at loading functions from shared object files other than those containing legitimate UDFs. If you have older UDFs that contain only the `xxx` symbol and that cannot be recompiled to include an auxiliary symbol, it may be necessary to specify the `--allow-suspicious-udfs` option. Otherwise, you should avoid enabling this capability.

UDF object files cannot be placed in arbitrary directories. They must be located in some system directory that the dynamic linker is configured to search. To enforce this restriction and prevent attempts at specifying pathnames outside of directories searched by the dynamic linker, MySQL checks the shared object file name specified in `CREATE FUNCTION` statements for pathname delimiter characters. As of MySQL 4.0.24, 4.1.10a, and 5.0.3, MySQL also checks for pathname delimiters in filenames stored in the `mysql.func` table when it loads functions. This prevents attempts at specifying illegitimate pathnames through direct manipulation of the `mysql.func` table. For information about UDFs and the runtime linker, see Section 27.2.3.5, “Compiling and Installing User-defined Functions”.

27.2.4. Adding a New Native Function

The procedure for adding a new native function is described here. Note that you cannot add native functions to a binary distribution because the procedure involves modifying MySQL source code. You must compile MySQL yourself from a source distribution. Also note that if you migrate to another version of MySQL (for example, when a new version is released), you need to repeat the procedure with the new version.

To add a new native MySQL function, follow these steps:

1. Add one line to `lex.h` that defines the function name in the `sql_functions[]` array.
2. If the function prototype is simple (just takes zero, one, two or three arguments), you should in `lex.h` specify `SYM(FUNC_ARGN)` (where *N* is the number of arguments) as the second argument in the `sql_functions[]` array and add a function that creates a function object in `item_create.cc`. Take a look at “ABS” and `create_funcs_abs()` for an example of this.

If the function prototype is complicated (for example, if it takes a variable number of arguments), you should add two lines to `sql_yacc.yy`. One indicates the preprocessor symbol that `yacc` should define (this should be added at the beginning of the file). Then define the function parameters and add an “item” with these parameters to the `simple_expr` parsing rule. For an example, check all occurrences of `ATAN` in `sql_yacc.yy` to see how this is done.

3. In `item_func.h`, declare a class inheriting from `Item_num_func` or `Item_str_func`, depending on whether your function returns a number or a string.
4. In `item_func.cc`, add one of the following declarations, depending on whether you are defining a numeric or string function:

```
double   Item_func_newname::val()
longlong Item_func_newname::val_int()
```

```
String *Item_func_newname::Str(String *str)
```

If you inherit your object from any of the standard items (like `Item_num_func`), you probably only have to define one of these functions and let the parent object take care of the other functions. For example, the `Item_str_func` class defines a `val()` function that executes `atof()` on the value returned by `::str()`.

5. You should probably also define the following object function:

```
void Item_func_newname::fix_length_and_dec()
```

This function should at least calculate `max_length` based on the given arguments. `max_length` is the maximum number of characters the function may return. This function should also set `maybe_null = 0` if the main function can't return a `NULL` value. The function can check whether any of the function arguments can return `NULL` by checking the arguments' `maybe_null` variable. You can take a look at `Item_func_mod::fix_length_and_dec` for a typical example of how to do this.

All functions must be thread-safe. In other words, don't use any global or static variables in the functions without protecting them with mutexes)

If you want to return `NULL`, from `::val()`, `::val_int()` or `::str()` you should set `null_value` to 1 and return 0.

For `::str()` object functions, there are some additional considerations to be aware of:

- The `String *str` argument provides a string buffer that may be used to hold the result. (For more information about the `String` type, take a look at the `sql_string.h` file.)
- The `::str()` function should return the string that holds the result or `(char*) 0` if the result is `NULL`.
- All current string functions try to avoid allocating any memory unless absolutely necessary!

27.3. Adding New Procedures to MySQL

In MySQL, you can define a procedure in C++ that can access and modify the data in a query before it is sent to the client. The modification can be done on a row-by-row or `GROUP BY` level.

We have created an example procedure in MySQL 3.23 to show you what can be done.

Additionally, we recommend that you take a look at `mysqlua`. With this you can use the LUA language to load a procedure at runtime into **mysqld**.

27.3.1. Procedure Analyse

```
analyse([max_elements],[max_memory])
```

This procedure is defined in the `sql/sql_analyse.cc`. This examines the result from your query and returns an analysis of the results:

- `max_elements` (default 256) is the maximum number of distinct values `analyse` does notice per column. This is used by `analyse` to check whether the optimal column type should be of type `ENUM`.
- `max_memory` (default 8192) is the maximum amount of memory that `analyse` should alloc-

ate per column while trying to find all distinct values.

```
SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements,max_memory])
```

27.3.2. Writing a Procedure

For the moment, the only documentation for this is the source.

You can find all information about procedures by examining the following files:

- `sql/sql_analyse.cc`
- `sql/procedure.h`
- `sql/procedure.cc`
- `sql/sql_select.cc`

Appendix A. Problems and Common Errors

This appendix lists some common problems and error messages that you may encounter. It describes how to determine the causes of the problems and what to do to solve them.

A.1. How to Determine What Is Causing a Problem

When you run into a problem, the first thing you should do is to find out which program or piece of equipment is causing it:

- If you have one of the following symptoms, then it is probably a hardware problem (such as memory, motherboard, CPU, or hard disk) or kernel problem:
 - The keyboard doesn't work. This can normally be checked by pressing the Caps Lock key. If the Caps Lock light doesn't change, you have to replace your keyboard. (Before doing this, you should try to restart your computer and check all cables to the keyboard.)
 - The mouse pointer doesn't move.
 - The machine doesn't answer to a remote machine's pings.
 - Other programs that are not related to MySQL don't behave correctly.
 - Your system restarted unexpectedly. (A faulty user-level program should never be able to take down your system.)

In this case, you should start by checking all your cables and run some diagnostic tool to check your hardware! You should also check whether there are any patches, updates, or service packs for your operating system that could likely solve your problem. Check also that all your libraries (such as `glibc`) are up to date.

It's always good to use a machine with ECC memory to discover memory problems early.

- If your keyboard is locked up, you may be able to recover by logging in to your machine from another machine and executing `kbd_mode -a`.
- Please examine your system log file (`/var/log/messages` or similar) for reasons for your problem. If you think the problem is in MySQL, you should also examine MySQL's log files. See Section 5.10, "The MySQL Log Files".
- If you don't think you have hardware problems, you should try to find out which program is causing problems. Try using **top**, **ps**, Task Manager, or some similar program, to check which program is taking all CPU or is locking the machine.
- Use **top**, **df**, or a similar program to check whether you are out of memory, disk space, file descriptors, or some other critical resource.
- If the problem is some runaway process, you can always try to kill it. If it doesn't want to die, there is probably a bug in the operating system.

If after you have examined all other possibilities and you have concluded that the MySQL server or a MySQL client is causing the problem, it's time to create a bug report for our mailing list or our support team. In the bug report, try to give a very detailed description of how the system is behaving and what you think is happening. You should also state why you think that MySQL is causing the

problem. Take into consideration all the situations in this chapter. State any problems exactly how they appear when you examine your system. Use the “copy and paste” method for any output and error messages from programs and log files.

Try to describe in detail which program is not working and all symptoms you see. We have in the past received many bug reports that state only “the system doesn't work.” This doesn't provide us with any information about what could be the problem.

If a program fails, it's always useful to know the following information:

- Has the program in question made a segmentation fault (did it dump core)?
- Is the program taking up all available CPU time? Check with **top**. Let the program run for a while, it may simply be evaluating something computationally intensive.
- If the **mysqld** server is causing problems, can you get any response from it with **mysqladmin -u root ping** or **mysqladmin -u root processlist**?
- What does a client program say when you try to connect to the MySQL server? (Try with **mysql**, for example.) Does the client jam? Do you get any output from the program?

When sending a bug report, you should follow the outline described in Section 1.6.1.2, “Asking Questions or Reporting Bugs”.

A.2. Common Errors When Using MySQL Programs

This section lists some errors that users frequently encounter when running MySQL programs. Although the problems show up when you try to run client programs, the solutions to many of the problems involves changing the configuration of the MySQL server.

A.2.1. Access denied

An `Access denied` error can have many causes. Often the problem is related to the MySQL accounts that the server allows client programs to use when connecting. See Section 5.6.8, “Causes of Access denied Errors”. See Section 5.6.2, “How the Privilege System Works”.

A.2.2. Can't connect to [local] MySQL server

A MySQL client on Unix can connect to the **mysqld** server in two different ways: By using a Unix socket file to connect through a file in the filesystem (default `/tmp/mysql.sock`), or by using TCP/IP, which connects through a port number. A Unix socket file connection is faster than TCP/IP, but can be used only when connecting to a server on the same computer. A Unix socket file is used if you don't specify a hostname or if you specify the special hostname `localhost`.

If the MySQL server is running on Windows 9x or Me, you can connect only via TCP/IP. If the server is running on Windows NT, 2000, XP, or 2003 and is started with the `--enable-named-pipe` option, you can also connect with named pipes if you run the client on the host where the server is running. The name of the named pipe is `MySQL` by default. If you don't give a hostname when connecting to **mysqld**, a MySQL client first tries to connect to the named pipe. If that doesn't work, it connects to the TCP/IP port. You can force the use of named pipes on Windows by using `.` as the hostname.

The error (2002) `Can't connect to ...` normally means that there is no MySQL server running on the system or that you are using an incorrect Unix socket filename or TCP/IP port number when trying to connect to the server.

Start by checking whether there is a process named **mysqld** running on your server host. (Use **ps xa**

| **grep mysqld** on Unix or the Task Manager on Windows.) If there is no such process, you should start the server. See Section 2.9.2.3, “Starting and Troubleshooting the MySQL Server”.

If a **mysqld** process is running, you can check it by trying the following commands. The port number or Unix socket filename might be different in your setup. `host_ip` represents the IP number of the machine where the server is running.

```
shell> mysqladmin version
shell> mysqladmin variables
shell> mysqladmin -h `hostname` version variables
shell> mysqladmin -h `hostname` --port=3306 version
shell> mysqladmin -h host_ip version
shell> mysqladmin --protocol=socket --socket=/tmp/mysql.sock version
```

Note the use of backticks rather than forward quotes with the `hostname` command; these cause the output of `hostname` (that is, the current hostname) to be substituted into the **mysqladmin** command. If you have no `hostname` command or are running on Windows, you can manually type the hostname of your machine (without backticks) following the `-h` option. You can also try `-h 127.0.0.1` to connect with TCP/IP to the local host.

Here are some reasons the Can't connect to local MySQL server error might occur:

- **mysqld** is not running. Check your operating system's process list to ensure the **mysqld** process is present.
- You are running on a system that uses MIT-pthreads. If you are running on a system that doesn't have native threads, **mysqld** uses the MIT-pthreads package. See Section 2.1.1, “Operating Systems Supported by MySQL”. However, not all MIT-pthreads versions support Unix socket files. On a system without socket file support, you must always specify the hostname explicitly when connecting to the server. Try using this command to check the connection to the server:

```
shell> mysqladmin -h `hostname` version
```

- Someone has removed the Unix socket file that **mysqld** uses (`/tmp/mysql.sock` by default). For example, you might have a **cron** job that removes old files from the `/tmp` directory. You can always run **mysqladmin version** to check whether the Unix socket file that **mysqladmin** is trying to use really exists. The fix in this case is to change the **cron** job to not remove `mysql.sock` or to place the socket file somewhere else. See Section A.4.5, “How to Protect or Change the MySQL Socket File `/tmp/mysql.sock`”.
- You have started the **mysqld** server with the `--socket=/path/to/socket` option, but forgotten to tell client programs the new name of the socket file. If you change the socket pathname for the server, you must also notify the MySQL clients. You can do this by providing the same `--socket` option when you run client programs. You also need to ensure that clients have permission to access the `mysql.sock` file. To find out where the socket file is, you can do:

```
shell> netstat -ln | grep mysql
```

See Section A.4.5, “How to Protect or Change the MySQL Socket File `/tmp/mysql.sock`”.

- You are using Linux and one server thread has died (dumped core). In this case, you must kill the other **mysqld** threads (for example, with `kill` or with the `mysql_zap` script) before you can restart the MySQL server. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.
- The server or client program might not have the proper access privileges for the directory that holds the Unix socket file or the socket file itself. In this case, you must either change the access privileges for the directory or socket file so that the server and clients can access them, or restart **mysqld** with a `--socket` option that specifies a socket filename in a directory where the server can create it and where client programs can access it.

If you get the error message `Can't connect to MySQL server on some_host`, you can try the following things to find out what the problem is:

- Check whether the server is running on that host by executing `telnet some_host 3306` and pressing the Enter key a couple of times. (3306 is the default MySQL port number. Change the value if your server is listening to a different port.) If there is a MySQL server running and listening to the port, you should get a response that includes the server's version number. If you get an error such as `telnet: Unable to connect to remote host: Connection refused`, then there is no server running on the given port.
- If the server is running on the local host, try using `mysqladmin -h localhost variables` to connect using the Unix socket file. Verify the TCP/IP port number that the server is configured to listen to (it is the value of the `port` variable.)
- Make sure that your `mysqld` server was not started with the `--skip-networking` option. If it was, you cannot connect to it using TCP/IP.
- Check to make sure that there is no firewall blocking access to MySQL. Applications such as ZoneAlarm and the Windows XP personal firewall may need to be configured to allow external access to a MySQL server.

A.2.3. Client does not support authentication protocol

MySQL 4.1 and up uses an authentication protocol based on a password hashing algorithm that is incompatible with that used by older clients. If you upgrade the server to 4.1, attempts to connect to it with an older client may fail with the following message:

```
shell> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

To solve this problem, you should use one of the following approaches:

- Upgrade all client programs to use a 4.1.1 or newer client library.
- When connecting to the server with a pre-4.1 client program, use an account that still has a pre-4.1-style password.
- Reset the password to pre-4.1 style for each user that needs to use a pre-4.1 client program. This can be done using the `SET PASSWORD` statement and the `OLD_PASSWORD()` function:

```
mysql> SET PASSWORD FOR
      -> 'some_user'@'some_host' = OLD_PASSWORD('newpwd');
```

Alternatively, use `UPDATE` and `FLUSH PRIVILEGES`:

```
mysql> UPDATE mysql.user SET Password = OLD_PASSWORD('newpwd')
      -> WHERE Host = 'some_host' AND User = 'some_user';
mysql> FLUSH PRIVILEGES;
```

Substitute the password you want to use for `'newpwd'` in the preceding examples. MySQL cannot tell you what the original password was, so you'll need to pick a new one.

- Tell the server to use the older password hashing algorithm:
 1. Start `mysqld` with the `--old-passwords` option.

2. Assign an old-format password to each account that has had its password updated to the longer 4.1 format. You can identify these accounts with the following query:

```
mysql> SELECT Host, User, Password FROM mysql.user
-> WHERE LENGTH(Password) > 16;
```

For each account record displayed by the query, use the `Host` and `User` values and assign a password using the `OLD_PASSWORD()` function and either `SET PASSWORD` or `UPDATE`, as described earlier.

Note: In PHP, the `mysql` extension does not support the new authentication protocol in MySQL 4.1.1 and higher. This is true regardless of the PHP version being used. If you wish to use the `mysql` extension with MySQL 4.1 or newer, you will need to follow one of the options discussed above for configuring MySQL to work with old clients. The `mysqli` extension (stands for "MySQL, Improved"; new in PHP 5) is compatible with the improved password hashing employed in MySQL 4.1 and higher, and no special configuration of MySQL need be done in order to use this newer MySQL client library for PHP. For more information about the `mysqli` extension, see <http://php.net/mysqli>.

For additional background on password hashing and authentication, see Section 5.6.9, "Password Hashing in MySQL 4.1".

A.2.4. Password Fails When Entered Interactively

MySQL client programs prompt for a password when invoked with a `--password` or `-p` option that has no following password value:

```
shell> mysql -u user_name -p
Enter password:
```

On some systems, you may find that your password works when specified in an option file or on the command line, but not when you enter it interactively at the `Enter password:` prompt. This occurs when the library provided by the system to read passwords limits password values to a small number of characters (typically eight). That is a problem with the system library, not with MySQL. To work around it, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

A.2.5. Host '*host_name*' is blocked

If you get the following error, it means that **mysqld** has received many connect requests from the host '*host_name*' that have been interrupted in the middle:

```
Host 'host_name' is blocked because of many connection errors.
Unblock with 'mysqladmin flush-hosts'
```

The number of interrupted connect requests allowed is determined by the value of the `max_connect_errors` system variable. After `max_connect_errors` failed requests, **mysqld** assumes that something is wrong (for example, that someone is trying to break in), and blocks the host from further connections until you execute a **mysqladmin flush-hosts** command or issue a `FLUSH HOSTS` statement. See Section 5.3.3, "Server System Variables".

By default, **mysqld** blocks a host after 10 connection errors. You can adjust the value by starting the server like this:

```
shell> mysqld_safe --max_connect_errors=10000 &
```

If you get this error message for a given host, you should first verify that there isn't anything wrong

with TCP/IP connections from that host. If you are having network problems, it does you no good to increase the value of the `max_connect_errors` variable.

A.2.6. Too many connections

If you get a `Too many connections` error when you try to connect to the **mysqld** server, this means that all available connections are in use by other clients.

The number of connections allowed is controlled by the `max_connections` system variable. Its default value is 100. If you need to support more connections, you should restart **mysqld** with a larger value for this variable.

mysqld actually allows `max_connections+1` clients to connect. The extra connection is reserved for use by accounts that have the `SUPER` privilege. By granting the `SUPER` privilege to administrators and not to normal users (who should not need it), an administrator can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See Section 13.5.4.15, “`SHOW PROCESSLIST` Syntax”.

The maximum number of connections MySQL can support depends on the quality of the thread library on a given platform. Linux or Solaris should be able to support 500-1000 simultaneous connections, depending on how much RAM you have and what your clients are doing. Static Linux binaries provided by MySQL AB can support up to 4000 connections.

A.2.7. Out of memory

If you issue a query using the **mysql** client program and receive an error like the following one, it means that **mysql** does not have enough memory to store the entire query result:

```
mysql: Out of memory at line 42, 'malloc.c'  
mysql: needed 8136 byte (8k), memory in use: 12481367 bytes (12189k)  
ERROR 2008: MySQL client ran out of memory
```

To remedy the problem, first check whether your query is correct. Is it reasonable that it should return so many rows? If not, correct the query and try again. Otherwise, you can invoke **mysql** with the `--quick` option. This causes it to use the `mysql_use_result()` C API function to retrieve the result set, which places less of a load on the client (but more on the server).

A.2.8. MySQL server has gone away

This section also covers the related `Lost connection to server during query` error.

The most common reason for the `MySQL server has gone away` error is that the server timed out and closed the connection. In this case, you normally get one of the following error codes (which one you get is operating system-dependent):

Error Code	Description
<code>CR_SERVER_GONE_ERROR</code>	The client couldn't send a question to the server.
<code>CR_SERVER_LOST</code>	The client didn't get an error when writing to the server, but it didn't get a full answer (or any answer) to the question.

By default, the server closes the connection after eight hours if nothing has happened. You can change the time limit by setting the `wait_timeout` variable when you start **mysqld**. See Section 5.3.3, “Server System Variables”.

If you have a script, you just have to issue the query again for the client to do an automatic reconnection. This assumes that you have automatic reconnection in the client enabled (which is the default for the **mysql** command-line client).

Some other common reasons for the `MySQL server has gone away` error are:

- You (or the db administrator) has killed the running thread with a `KILL` statement or a **`mysql-admin kill`** command.
- You tried to run a query after closing the connection to the server. This indicates a logic error in the application that should be corrected.
- You got a timeout from the TCP/IP connection on the client side. This may happen if you have been using the commands: `mysql_options(..., MYSQL_OPT_READ_TIMEOUT, ...)` or `mysql_options(..., MYSQL_OPT_WRITE_TIMEOUT, ...)`. In this case increasing the timeout may help solve the problem.
- You have encountered a timeout on the server side and the automatic reconnection in the client is disabled (the `reconnect` flag in the `MYSQL` structure is equal to 0).
- You are using a windows client and the server had dropped the connection (probably because `wait_timeout` expired) before the command was issued.

The problem on windows is that in some cases MySQL doesn't get an error from the OS when writing to the TCP/IP connection to the server, but instead gets the error when trying to read the answer from connection.

In this case, even if the `reconnect` flag in the `MYSQL` structure is equal to 1, MySQL does not automatically reconnect and re-issue the query as it doesn't know if the server did get the original query or not.

The solution to this is to either do a `mysql_ping` on the connection if there has been a long time since the last query (this is what `MyODBC` does) or set `wait_timeout` on the **`mysqld`** server so high that it in practice never times out.

- You can also get these errors if you send a query to the server that is incorrect or too large. If **`mysqld`** receives a packet that is too large or out of order, it assumes that something has gone wrong with the client and closes the connection. If you need big queries (for example, if you are working with big `BLOB` columns), you can increase the query limit by setting the server's `max_allowed_packet` variable, which has a default value of 1MB. You may also need to increase the maximum packet size on the client end. More information on setting the packet size is given in Section A.2.9, "Packet too large".
- You also get a lost connection if you are sending a packet 16MB or larger if your client is older than 4.0.8 and your server is 4.0.8 and above, or the other way around.
- You may also see the `MySQL server has gone away` error if MySQL is started with the `--skip-networking` option.
- You have encountered a bug where the server died while executing the query.

You can check whether the MySQL server died and restarted by executing **`mysqladmin version`** and examining the server's uptime. If the client connection was broken because **`mysqld`** crashed and restarted, you should concentrate on finding the reason for the crash. Start by checking whether issuing the query again kills the server again. See Section A.4.2, "What to Do If MySQL Keeps Crashing".

You can get more information about the lost connections by starting `mysqld` with the `-log-warnings=2` option. This logs some of the disconnected errors in the `hostname.err` file. See Section 5.10.1, "The Error Log".

If you want to create a bug report regarding this problem, be sure that you include the following information:

- Indicate whether or not the MySQL server died. You can find information about this in the serv-

er error log. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.

- If a specific query kills **mysqld** and the tables involved were checked with `CHECK TABLE` before you ran the query, can you provide a reproducible test case? See Section E.1.6, “Making a Test Case If You Experience Table Corruption”.
- What is the value of the `wait_timeout` system variable in the MySQL server? (**mysqladmin variables** gives you the value of this variable.)
- Have you tried to run **mysqld** with the `--log` option to determine whether the problem query appears in the log?

See also See Section A.2.10, “Communication Errors and Aborted Connections”.

See Section 1.6.1.2, “Asking Questions or Reporting Bugs”.

A.2.9. Packet too large

A communication packet is a single SQL statement sent to the MySQL server or a single row that is sent to the client.

In MySQL 3.23, the largest possible packet is 16MB, due to limits in the client/server protocol. In MySQL 4.0.1 and up, the limit is 1GB.

When a MySQL client or the **mysqld** server receives a packet bigger than `max_allowed_packet` bytes, it issues a `Packet too large` error and closes the connection. With some clients, you may also get a `Lost connection to MySQL server during query` error if the communication packet is too large.

Both the client and the server have their own `max_allowed_packet` variable, so if you want to handle big packets, you must increase this variable both in the client and in the server.

If you are using the **mysql** client program, its default `max_allowed_packet` variable is 16MB. That is also the maximum value before MySQL 4.0. To set a larger value from 4.0 on, start **mysql** like this:

```
mysql> mysql --max_allowed_packet=32M
```

That sets the packet size to 32MB.

The server's default `max_allowed_packet` value is 1MB. You can increase this if the server needs to handle big queries (for example, if you are working with big BLOB columns). For example, to set the variable to 16MB, start the server like this:

```
mysql> mysqld --max_allowed_packet=16M
```

Before MySQL 4.0, use this syntax instead:

```
mysql> mysqld --set-variable=max_allowed_packet=16M
```

You can also use an option file to set `max_allowed_packet`. For example, to set the size for the server to 16MB, add the following lines in an option file:

```
[mysqld]  
max_allowed_packet=16M
```

Before MySQL 4.0, use this syntax instead:

```
[mysqld]
```

```
set-variable = max_allowed_packet=16M
```

It's safe to increase the value of this variable because the extra memory is allocated only when needed. For example, **mysqld** allocates more memory only when you issue a long query or when **mysqld** must return a large result row. The small default value of the variable is a precaution to catch incorrect packets between the client and server and also to ensure that you don't run out of memory by using large packets accidentally.

You can also get strange problems with large packets if you are using large BLOB values but have not given **mysqld** access to enough memory to handle the query. If you suspect this is the case, try adding **ulimit -d 256000** to the beginning of the **mysqld_safe** script and restarting **mysqld**.

A.2.10. Communication Errors and Aborted Connections

The server error log can be a useful source of information about connection problems. See Section 5.10.1, “The Error Log”. Starting with MySQL 3.23.40, if you start the server with the `--warnings` option (or `--log-warnings` from MySQL 4.0.3 on), you might find messages like this in your error log:

```
010301 14:38:23 Aborted connection 854 to db: 'users' user: 'josh'
```

If `Aborted connections` messages appear in the error log, the cause can be any of the following:

- The client program did not call `mysql_close()` before exiting.
- The client had been sleeping more than `wait_timeout` or `interactive_timeout` seconds without issuing any requests to the server. See Section 5.3.3, “Server System Variables”.
- The client program ended abruptly in the middle of a data transfer.

When any of these things happen, the server increments the `Aborted_clients` status variable.

The server increments the `Aborted_connects` status variable when the following things happen:

- A client doesn't have privileges to connect to a database.
- A client uses an incorrect password.
- A connection packet doesn't contain the right information.
- It takes more than `connect_timeout` seconds to get a connect packet. See Section 5.3.3, “Server System Variables”.

If these kinds of things happen, it might indicate that someone is trying to break into your server!

Other reasons for problems with aborted clients or aborted connections:

- Use of Ethernet protocol with Linux, both half and full duplex. Many Linux Ethernet drivers have this bug. You should test for this bug by transferring a huge file via FTP between the client and server machines. If a transfer goes in burst-pause-burst-pause mode, you are experiencing a Linux duplex syndrome. The only solution is switching the duplex mode for both your network card and hub/switch to either full duplex or to half duplex and testing the results to determine the

best setting.

- Some problem with the thread library that causes interrupts on reads.
- Badly configured TCP/IP.
- Faulty Ethernets, hubs, switches, cables, and so forth. This can be diagnosed properly only by replacing hardware.
- The `max_allowed_packet` variable value is too small or queries require more memory than you have allocated for **mysqld**. See Section A.2.9, “Packet too large”.

See also See Section A.2.8, “MySQL server has gone away”.

A.2.11. The table is full

There are several ways a full-table error can occur:

- You are using a MySQL server older than 3.23 and an in-memory temporary table becomes larger than `tmp_table_size` bytes. To avoid this problem, you can use the `-O tmp_table_size=#` option to make **mysqld** increase the temporary table size or use the SQL option `SQL_BIG_TABLES` before you issue the problematic query. See Section 13.5.3, “SET Syntax”.

You can also start **mysqld** with the `--big-tables` option. This is exactly the same as using `SQL_BIG_TABLES` for all queries.

As of MySQL 3.23, this problem should not occur. If an in-memory temporary table becomes larger than `tmp_table_size`, the server automatically converts it to a disk-based MyISAM table.

- You are using InnoDB tables and run out of room in the InnoDB tablespace. In this case, the solution is to extend the InnoDB tablespace. See Section 15.8, “Adding and Removing InnoDB Data and Log Files”.
- You are using ISAM or MyISAM tables on an operating system that supports files only up to 2GB in size and you have hit this limit for the data file or index file.
- You are using a MyISAM table and the space required for the table exceeds what is allowed by the internal pointer size. (If you don't specify the `MAX_ROWS` table option when you create a table, MySQL uses the `myisam_data_pointer_size` system variable. Its default value of 4 bytes is enough to allow only 4GB of data.) See Section 5.3.3, “Server System Variables”.

You can check the maximum data/index sizes by using this statement:

```
SHOW TABLE STATUS FROM database LIKE 'tbl_name';
```

You also can use **myisamchk -dv /path/to/table-index-file**.

If the pointer size is too small, you can fix the problem by using `ALTER TABLE`:

```
ALTER TABLE tbl_name MAX_ROWS=1000000000 AVG_ROW_LENGTH=nnn;
```

You have to specify `AVG_ROW_LENGTH` only for tables with BLOB or TEXT columns; in this case, MySQL can't optimize the space required based only on the number of rows.

A.2.12. Can't create/write to file

If you get an error of the following type for some queries, it means that MySQL cannot create a temporary file for the result set in the temporary directory:

```
Can't create/write to file '\\sqla3fe_0.ism'.
```

The preceding error is a typical message for Windows; the Unix message is similar.

One fix is to start **mysqld** with the `--tmpdir` option or to add the option to the `[mysqld]` section of your option file. For example, to specify a directory of `C:\temp`, use these lines:

```
[mysqld]
tmpdir=C:/temp
```

The `C:\temp` directory must exist and have sufficient space for the MySQL server to write to. See Section 4.3.2, “Using Option Files”.

Another cause of this error can be permissions issues. Make sure that the MySQL server can write to the `tmpdir` directory.

Check also the error code that you get with **pererror**. One reason the server cannot write to a table is that the filesystem is full:

```
shell> pererror 28
Error code 28: No space left on device
```

A.2.13. Commands out of sync

If you get `Commands out of sync; you can't run this command now in your client code, you are calling client functions in the wrong order.`

This can happen, for example, if you are using `mysql_use_result()` and try to execute a new query before you have called `mysql_free_result()`. It can also happen if you try to execute two queries that return data without calling `mysql_use_result()` or `mysql_store_result()` in between.

A.2.14. Ignoring user

If you get the following error, it means that when **mysqld** was started or when it reloaded the grant tables, it found an account in the `user` table that had an invalid password.

```
Found wrong password for user 'some_user'@'some_host'; ignoring user
```

As a result, the account is simply ignored by the permission system.

The following list indicates possible causes of and fixes for this problem:

- You may be running a new version of **mysqld** with an old `user` table. You can check this by executing **mysqlshow mysql user** to see whether the `Password` column is shorter than 16 characters. If so, you can correct this condition by running the `scripts/add_long_password` script.
- The account has an old password (eight characters long) and you didn't start **mysqld** with the `--old-protocol` option. Update the account in the `user` table to have a new password or restart **mysqld** with the `--old-protocol` option.
- You have specified a password in the `user` table without using the `PASSWORD()` function. Use **mysql** to update the account in the `user` table with a new password, making sure to use the

PASSWORD() function:

```
mysql> UPDATE user SET Password=PASSWORD('newpwd')
      -> WHERE User='some_user' AND Host='some_host';
```

A.2.15. Table '*tbl_name*' doesn't exist

If you get either of the following errors, it usually means that no table exists in the current database with the given name:

```
Table 'tbl_name' doesn't exist
Can't find file: 'tbl_name' (errno: 2)
```

In some cases, it may be that the table does exist but that you are referring to it incorrectly:

- Because MySQL uses directories and files to store databases and tables, database and table names are case sensitive if they are located on a filesystem that has case-sensitive filenames.
- Even for filesystems that are not case sensitive, such as on Windows, all references to a given table within a query must use the same lettercase.

You can check which tables are in the current database with `SHOW TABLES`. See Section 13.5.4, “SHOW Syntax”.

A.2.16. Can't initialize character set

You might see an error like this if you have character set problems:

```
MySQL Connection Failed: Can't initialize character set charset_name
```

This error can have any of the following causes:

- The character set is a multi-byte character set and you have no support for the character set in the client. In this case, you need to recompile the client by running **configure** with the `--with-charset=charset_name` or `--with-extra-charsets=charset_name` option. See Section 2.8.2, “Typical **configure** Options”.

All standard MySQL binaries are compiled with `--with-extra-character-sets=complex`, which enables support for all multi-byte character sets. See Section 5.9.1, “The Character Set Used for Data and Sorting”.

- The character set is a simple character set that is not compiled into **mysqld**, and the character set definition files are not in the place where the client expects to find them.

In this case, you need to use one of the following methods to solve the problem:

- Recompile the client with support for the character set. See Section 2.8.2, “Typical **configure** Options”.
- Specify to the client the directory where the character set definition files are located. For many clients, you can do this with the `--character-sets-dir` option.
- Copy the character definition files to the path where the client expects them to be.

A.2.17. File Not Found

If you get ERROR `'...'` not found (errno: 23), Can't open file: ... (errno: 24), or any other error with errno 23 or errno 24 from MySQL, it means that you haven't allocated enough file descriptors for the MySQL server. You can use the **perror** utility to get a description of what the error number means:

```
shell> perror 23
Error code 23: File table overflow
shell> perror 24
Error code 24: Too many open files
shell> perror 11
Error code 11: Resource temporarily unavailable
```

The problem here is that **mysqld** is trying to keep open too many files simultaneously. You can either tell **mysqld** not to open so many files at once or increase the number of file descriptors available to **mysqld**.

To tell **mysqld** to keep open fewer files at a time, you can make the table cache smaller by reducing the value of the `table_cache` system variable (the default value is 64). Reducing the value of `max_connections` also reduces the number of open files (the default value is 100).

To change the number of file descriptors available to **mysqld**, you can use the `--open-files-limit` option to **mysqld_safe** or (as of MySQL 3.23.30) set the `open_files_limit` system variable. See Section 5.3.3, "Server System Variables". The easiest way to set these values is to add an option to your option file. See Section 4.3.2, "Using Option Files". If you have an old version of **mysqld** that doesn't support setting the open files limit, you can edit the **mysqld_safe** script. There is a commented-out line `ulimit -n 256` in the script. You can remove the '#' character to uncomment this line, and change the number 256 to set the number of file descriptors to be made available to **mysqld**.

`--open-files-limit` and **ulimit** can increase the number of file descriptors, but only up to the limit imposed by the operating system. There is also a "hard" limit that can be overridden only if you start **mysqld_safe** or **mysqld** as `root` (just remember that you also need to start the server with the `--user` option in this case so that it does not continue to run as `root` after it starts up). If you need to increase the operating system limit on the number of file descriptors available to each process, consult the documentation for your system.

Note: If you run the **tcsh** shell, **ulimit** does not work! **tcsh** also reports incorrect values when you ask for the current limits. In this case, you should start **mysqld_safe** using **sh**.

A.3. Installation-Related Issues

A.3.1. Problems Linking to the MySQL Client Library

When you are linking an application program to use the MySQL client library, you might get undefined reference errors for symbols that start with `mysql_`, such as those shown here:

```
/tmp/ccFKsdPa.o: In function `main':
/tmp/ccFKsdPa.o(.text+0xb): undefined reference to `mysql_init'
/tmp/ccFKsdPa.o(.text+0x31): undefined reference to `mysql_real_connect'
/tmp/ccFKsdPa.o(.text+0x57): undefined reference to `mysql_real_connect'
/tmp/ccFKsdPa.o(.text+0x69): undefined reference to `mysql_error'
/tmp/ccFKsdPa.o(.text+0x9a): undefined reference to `mysql_close'
```

You should be able to solve this problem by adding `-Ldir_path -lmysqlclient` at the end of your link command, where `dir_path` represents the pathname of the directory where the client library is located. To determine the correct directory, try this command:

```
shell> mysql_config --libs
```

The output from **mysql_config** might indicate other libraries that should be specified on the link

command as well.

If you get undefined reference errors for the `uncompress` or `compress` function, add `-lz` to the end of your link command and try again.

If you get undefined reference errors for a function that should exist on your system, such as `connect`, check the manual page for the function in question to determine which libraries you should add to the link command.

You might get undefined reference errors such as the following for functions that don't exist on your system:

```
mf_format.o(.text+0x201): undefined reference to `__lxstat'
```

This usually means that your MySQL client library was compiled on a system that is not 100% compatible with yours. In this case, you should download the latest MySQL source distribution and compile MySQL yourself. See Section 2.8, “MySQL Installation Using a Source Distribution”.

You might get undefined reference errors at runtime when you try to execute a MySQL program. If these errors specify symbols that start with `mysql_` or indicate that the `mysqlclient` library can't be found, it means that your system can't find the shared `libmysqlclient.so` library. The fix for this is to tell your system to search for shared libraries where the library is located. Use whichever of the following methods is appropriate for your system:

- Add the path to the directory where `libmysqlclient.so` is located to the `LD_LIBRARY_PATH` environment variable.
- Add the path to the directory where `libmysqlclient.so` is located to the `LD_LIBRARY` environment variable.
- Copy `libmysqlclient.so` to some directory that is searched by your system, such as `/lib`, and update the shared library information by executing `ldconfig`.

Another way to solve this problem is by linking your program statically with the `-static` option, or by removing the dynamic MySQL libraries before linking your code. Before trying the second method, you should be sure that no other programs are using the dynamic libraries.

A.3.2. How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using normal user accounts beginning with MySQL 4.0.17 and 4.1.2. (Older MySQL versions required you to have administrator rights. This was a bug introduced in MySQL 3.23.54.)

On Unix, the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. In order to change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it's running (use `mysqladmin shutdown`).
2. Change the database directories and files so that `user_name` has privileges to read and write files in them (you might need to do this as the Unix `root` user):

```
shell> chown -R user_name /path/to/mysql/datadir
```

If you do not do this, the server is not able to access databases or tables when it runs as `user_name`.

If directories or files within the MySQL data directory are symbolic links, you'll also need to follow those links and change the directories and files they point to. `chown -R` might not fol-

low symbolic links for you.

3. Start the server as user `user_name`. If you are using MySQL 3.22 or later, another alternative is to start **mysqld** as the Unix `root` user and use the `--user=user_name` option. **mysqld** starts up, then switches to run as the Unix user `user_name` before accepting any connections.
4. To start the server as the given user automatically at system startup time, specify the username by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

```
[mysqld]
user=user_name
```

If your Unix machine itself isn't secured, you should assign passwords to the MySQL `root` accounts in the grant tables. Otherwise, any user with a login account on that machine can run the **mysql** client with a `--user=root` option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See Section 2.9, "Post-Installation Setup and Testing".

A.3.3. Problems with File Permissions

If you have problems with file permissions, the `UMASK` environment variable might be set incorrectly when **mysqld** starts. For example, MySQL might issue the following error message when you create a table:

```
ERROR: Can't find file: 'path/with/filename.frm' (Errcode: 13)
```

The default `UMASK` value is 0660. You can change this behavior by starting **mysqld_safe** as follows:

```
shell> UMASK=384 # = 600 in octal
shell> export UMASK
shell> mysqld_safe &
```

By default, MySQL creates database and RAID directories with an access permission value of 0700. You can modify this behavior by setting the `UMASK_DIR` variable. If you set its value, new directories are created with the combined `UMASK` and `UMASK_DIR` values. For example, if you want to give group access to all new directories, you can do this:

```
shell> UMASK_DIR=504 # = 770 in octal
shell> export UMASK_DIR
shell> mysqld_safe &
```

In MySQL 3.23.25 and above, MySQL assumes that the value for `UMASK` and `UMASK_DIR` is in octal if it starts with a zero.

See Appendix F, *Environment Variables*.

A.4. Administration-Related Issues

A.4.1. How to Reset the Root Password

If you have never set a `root` password for MySQL, the server does not require a password at all for connecting as `root`. However, it is recommended to set a password for each account. See Section 5.5.1, "General Security Guidelines".

If you set a `root` password previously, but have forgotten what it was, you can set a new password.

The following procedure is for Windows systems. The procedure for Unix systems is given later in this section.

The procedure under Windows:

1. Log on to your system as Administrator.
2. Stop the MySQL server if it is running. For a server that is running as a Windows service, go to the Services manager:

Start Menu -> Control Panel -> Administrative Tools -> Services

Then find the MySQL service in the list, and stop it.

If your server is not running as a service, you may need to use the Task Manager to force it to stop.

3. Create a text file and place the following command within it on a single line:

```
SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPassword');
```

Save the file with any name. For this example the file will be C:\mysql-init.txt.

4. Open a console window to get to the DOS command prompt:

Start Menu -> Run -> cmd

5. We are assuming that you installed MySQL to C:\mysql. If you installed MySQL to another location, adjust the following commands accordingly.

At the DOS command prompt, execute this command:

```
C:\> C:\mysql\bin\mysqld-nt --init-file=C:\mysql-init.txt
```

The contents of the init-file are executed at server startup, changing the root password. After the server has started successfully you should delete C:\mysql-init.txt.

Users of MySQL 4.1 and higher who install MySQL using the MySQL Installation Wizard may need to specify a defaults-file:

```
C:\>C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqld-nt.exe --defaults-file
```

The appropriate defaults-file setting can be found using the Services Manager:

Start Menu -> Control Panel -> Administrative Tools -> Services

Find the MySQL service in the list, right-click on it, and choose the Properties option. The Path to executable field contains the defaults-file setting.

6. Stop the MySQL server, then restart it in normal mode again. If you run the server as a service, start it from the Windows Services window. If you start the server manually, use whatever command you normally use.
7. You should be able to connect using the new password.

In a Unix environment, the procedure for resetting the root password is as follows:

1. Log on to your system as either the Unix root user or as the same user that the **mysqld** server runs as.

2. Locate the `.pid` file that contains the server's process ID. The exact location and name of this file depend on your distribution, hostname, and configuration. Common locations are `/var/lib/mysql/`, `/var/run/mysqld/`, and `/usr/local/mysql/data/`. Generally, the filename has the extension of `.pid` and begins with either `mysqld` or your system's hostname.

You can stop the MySQL server by sending a normal kill (not `kill -9`) to the **mysqld** process, using the pathname of the `.pid` file in the following command:

```
shell> kill `cat /mysql-data-directory/host_name.pid`
```

Note the use of backticks rather than forward quotes with the `cat` command; these cause the output of `cat` to be substituted into the `kill` command.

3. Create a text file and place the following command within it on a single line:

```
SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPassword');
```

Save the file with any name. For this example the file will be `~/mysql-init`.

4. Restart the MySQL server with the special `--init-file=~/mysql-init` option:

```
shell> mysqld_safe --init-file=~/mysql-init &
```

The contents of the init-file are executed at server startup, changing the root password. After the server has started successfully you should delete `~/mysql-init`.

5. You should be able to connect using the new password.

Alternatively, on any platform, you can set the new password using the **mysql** client:

1. Stop **mysqld** and restart it with the `--skip-grant-tables` option as described earlier.
2. Connect to the **mysqld** server with this command:

```
shell> mysql -u root
```

3. Issue the following statements in the **mysql** client:

```
mysql> UPDATE mysql.user SET Password=PASSWORD('newpwd')
-> WHERE User='root';
mysql> FLUSH PRIVILEGES;
```

Replace `newpwd` with the actual root password that you want to use.

4. You should be able to connect using the new password.

A.4.2. What to Do If MySQL Keeps Crashing

Each MySQL version is tested on many platforms before it is released. This doesn't mean that there are no bugs in MySQL, but if there are bugs, they should be very few and can be hard to find. If you have a problem, it always helps if you try to find out exactly what crashes your system, because you have a much better chance of getting the problem fixed quickly.

First, you should try to find out whether the problem is that the **mysqld** server dies or whether your problem has to do with your client. You can check how long your **mysqld** server has been up by executing **mysqladmin version**. If **mysqld** has died and restarted, you may find the reason by looking

in the server's error log. See Section 5.10.1, “The Error Log”.

On some systems, you can find in the error log a stack trace of where **mysqld** died that you can resolve with the `resolve_stack_dump` program. See Section E.1.4, “Using a Stack Trace”. Note that the variable values written in the error log may not always be 100% correct.

Many server crashes are caused by corrupted data files or index files. MySQL updates the files on disk with the `write()` system call after every SQL statement and before the client is notified about the result. (This is not true if you are running with `--delay-key-write`, in which case data files are written but not index files.) This means that data file contents are safe even if **mysqld** crashes, because the operating system ensures that the unflushed data is written to disk. You can force MySQL to flush everything to disk after every SQL statement by starting **mysqld** with the `--flush` option.

The preceding means that normally you should not get corrupted tables unless one of the following happens:

- The MySQL server or the server host was killed in the middle of an update.
- You have found a bug in **mysqld** that caused it to die in the middle of an update.
- Some external program is manipulating data files or index files at the same time as **mysqld** without locking the table properly.
- You are running many **mysqld** servers using the same data directory on a system that doesn't support good filesystem locks (normally handled by the `lockd` lock manager), or you are running multiple servers with the `--skip-external-locking` option.
- You have a crashed data file or index file that contains very corrupt data that confused **mysqld**.
- You have found a bug in the data storage code. This isn't likely, but it's at least possible. In this case, you can try to change the table type to another storage engine by using `ALTER TABLE` on a repaired copy of the table.

Because it is very difficult to know why something is crashing, first try to check whether things that work for others crash for you. Please try the following things:

- Stop the **mysqld** server with **mysqldadmin shutdown**, run **myisamchk --silent --force */*.MYI** from the data directory to check all MyISAM tables, and restart **mysqld**. This ensures that you are running from a clean state. See Chapter 5, *Database Administration*.
- Start **mysqld** with the `--log` option and try to determine from the information written to the log whether some specific query kills the server. About 95% of all bugs are related to a particular query. Normally, this is one of the last queries in the log file just before the server restarts. See Section 5.10.2, “The General Query Log”. If you can repeatedly kill MySQL with a specific query, even when you have checked all tables just before issuing it, then you have been able to locate the bug and should submit a bug report for it. See Section 1.6.1.3, “How to Report Bugs or Problems”.
- Try to make a test case that we can use to repeat the problem. See Section E.1.6, “Making a Test Case If You Experience Table Corruption”.
- Try running the tests in the `mysql-test` directory and the MySQL benchmarks. See Section 27.1.2, “MySQL Test Suite”. They should test MySQL rather well. You can also add code to the benchmarks that simulates your application. The benchmarks can be found in the `sql-bench` directory in a source distribution or, for a binary distribution, in the `sql-bench` directory under your MySQL installation directory.
- Try the `fork_big.pl` script. (It is located in the `tests` directory of source distributions.)
- If you configure MySQL for debugging, it is much easier to gather information about possible errors if something goes wrong. Configuring MySQL for debugging causes a safe memory alloc-

ator to be included that can find some errors. It also provides a lot of output about what is happening. Reconfigure MySQL with the `--with-debug` or `--with-debug=full` option to **configure** and then recompile. See Section E.1, “Debugging a MySQL Server”.

- Make sure that you have applied the latest patches for your operating system.
- Use the `--skip-external-locking` option to **mysqld**. On some systems, the `lockd` lock manager does not work properly; the `--skip-external-locking` option tells **mysqld** not to use external locking. (This means that you cannot run two **mysqld** servers on the same data directory and that you must be careful if you use **myisamchk**. Nevertheless, it may be instructive to try the option as a test.)
- Have you tried **mysqladmin -u root processlist** when **mysqld** appears to be running but not responding? Sometimes **mysqld** is not comatose even though you might think so. The problem may be that all connections are in use, or there may be some internal lock problem. **mysqladmin -u root processlist** usually is able to make a connection even in these cases, and can provide useful information about the current number of connections and their status.
- Run the command **mysqladmin -i 5 status** or **mysqladmin -i 5 -r status** in a separate window to produce statistics while you run your other queries.
- Try the following:
 1. Start **mysqld** from **gdb** (or another debugger). See Section E.1.3, “Debugging **mysqld** under **gdb**”.
 2. Run your test scripts.
 3. Print the backtrace and the local variables at the three lowest levels. In **gdb**, you can do this with the following commands when **mysqld** has crashed inside **gdb**:

```
backtrace
info local
up
info local
up
info local
```

With **gdb**, you can also examine which threads exist with `info threads` and switch to a specific thread with `thread #`, where `#` is the thread ID.

- Try to simulate your application with a Perl script to force MySQL to crash or misbehave.
- Send a normal bug report. See Section 1.6.1.3, “How to Report Bugs or Problems”. Be even more detailed than usual. Because MySQL works for many people, it may be that the crash results from something that exists only on your computer (for example, an error that is related to your particular system libraries).
- If you have a problem with tables containing dynamic-length rows and you are using only VARCHAR columns (not BLOB or TEXT columns), you can try to change all VARCHAR to CHAR with `ALTER TABLE`. This forces MySQL to use fixed-size rows. Fixed-size rows take a little extra space, but are much more tolerant to corruption.

The current dynamic row code has been in use at MySQL AB for several years with very few problems, but dynamic-length rows are by nature more prone to errors, so it may be a good idea to try this strategy to see whether it helps.

- Do not rule out your server hardware when diagnosing problems. Defective hardware can be the cause of data corruption. Particular attention should be paid to both RAMS and hard-drives when troubleshooting hardware.

A.4.3. How MySQL Handles a Full Disk

This section describes how MySQL responds to disk-full errors (such as "no space left on device"), and, as of MySQL 4.0.22, to quota-exceeded errors (such as "write failed" or "user block limit reached").

This section is relevant for writes to MyISAM tables. As of MySQL 4.1.9, it also applies for writes to binary log files and binary log index file, except that references to "row" and "record" should be understood to mean "event."

When a disk-full condition occurs, MySQL does the following:

- It checks once every minute to see whether there is enough space to write the current row. If there is enough space, it continues as if nothing had happened.
- Every 10 minutes it writes an entry to the log file, warning about the disk-full condition.

To alleviate the problem, you can take the following actions:

- To continue, you only have to free enough disk space to insert all records.
- To abort the thread, you must use **mysqladmin kill**. The thread is aborted the next time it checks the disk (in one minute).
- Other threads might be waiting for the table that caused the disk-full condition. If you have several "locked" threads, killing the one thread that is waiting on the disk-full condition allows the other threads to continue.

Exceptions to the preceding behavior are when you use `REPAIR TABLE` or `OPTIMIZE TABLE` or when the indexes are created in a batch after `LOAD DATA INFILE` or after an `ALTER TABLE` statement. All of these statements may create large temporary files that, if left to themselves, would cause big problems for the rest of the system. If the disk becomes full while MySQL is doing any of these operations, it removes the big temporary files and mark the table as crashed. The exception is that for `ALTER TABLE`, the old table is left unchanged.

A.4.4. Where MySQL Stores Temporary Files

MySQL uses the value of the `TMPDIR` environment variable as the pathname of the directory in which to store temporary files. If you don't have `TMPDIR` set, MySQL uses the system default, which is normally `/tmp`, `/var/tmp`, or `/usr/tmp`. If the filesystem containing your temporary file directory is too small, you can use the `--tmpdir` option to **mysqld** to specify a directory in a filesystem where you have enough space.

Starting from MySQL 4.1, the `--tmpdir` option can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (':') on Unix and semicolon characters(';') on Windows, NetWare, and OS/2. **Note:** To spread the load effectively, these paths should be located on different *physical* disks, not different partitions of the same disk.

If the MySQL server is acting as a replication slave, you should not set `--tmpdir` to point to a directory on a memory-based filesystem or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

MySQL creates all temporary files as hidden files. This ensures that the temporary files are removed if **mysqld** is terminated. The disadvantage of using hidden files is that you do not see a big temporary file that fills up the filesystem in which the temporary file directory is located.

When sorting (`ORDER BY` or `GROUP BY`), MySQL normally uses one or two temporary files. The

maximum disk space required is determined by the following expression:

```
(length of what is sorted + sizeof(row pointer))
* number of matched rows
* 2
```

The row pointer size is usually four bytes, but may grow in the future for really big tables.

For some `SELECT` queries, MySQL also creates temporary SQL tables. These are not hidden and have names of the form `SQL_*`.

`ALTER TABLE` creates a temporary table in the same directory as the original table.

A.4.5. How to Protect or Change the MySQL Socket File `/tmp/mysql.sock`

The default location for the Unix socket file that the server uses for communication with local clients is `/tmp/mysql.sock`. This might cause problems, because on some versions of Unix, anyone can delete files in the `/tmp` directory.

On most versions of Unix, you can protect your `/tmp` directory so that files can be deleted only by their owners or the superuser (`root`). To do this, set the `sticky` bit on the `/tmp` directory by logging in as `root` and using the following command:

```
shell> chmod +t /tmp
```

You can check whether the `sticky` bit is set by executing `ls -ld /tmp`. If the last permission character is `t`, the bit is set.

Another approach is to change the place where the server creates the Unix socket file. If you do this, you should also let client programs know the new location of the file. You can specify the file location in several ways:

- Specify the path in a global or local option file. For example, put the following lines in `/etc/my.cnf`:

```
[mysqld]
socket=/path/to/socket

[client]
socket=/path/to/socket
```

See Section 4.3.2, “Using Option Files”.

- Specify a `--socket` option on the command line to `mysqld_safe` and when you run client programs.
- Set the `MYSQL_UNIX_PORT` environment variable to the path of the Unix socket file.
- Recompile MySQL from source to use a different default Unix socket file location. Define the path to the file with the `--with-unix-socket-path` option when you run `configure`. See Section 2.8.2, “Typical `configure` Options”.

You can test whether the new socket location works by attempting to connect to the server with this command:

```
shell> mysqladmin --socket=/path/to/socket version
```

A.4.6. Time Zone Problems

If you have a problem with `SELECT NOW()` returning values in GMT and not your local time, you have to tell the server your current time zone. The same applies if `UNIX_TIMESTAMP()` returns the wrong value. This should be done for the environment in which the server runs; for example, in `mysqld_safe` or `mysql.server`. See Appendix F, *Environment Variables*.

You can set the time zone for the server with the `--timezone=timezone_name` option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`.

The allowable values for `--timezone` or `TZ` are system-dependent. Consult your operating system documentation to see what values are acceptable.

A.5. Query-Related Issues

A.5.1. Case Sensitivity in Searches

By default, MySQL searches are not case sensitive (although there are some character sets that are never case insensitive, such as `czech`). This means that if you search with `col_name LIKE 'a%'`, you get all column values that start with A or a. If you want to make this search case sensitive, make sure that one of the operands has a case sensitive or binary collation. For example, if you are comparing a column and a string that both have the `latin1` character set, you can use the `COLLATE` operator to cause either operand to have the `latin1_general_cs` or `latin1_bin` collation. For example:

```
col_name COLLATE latin1_general_cs LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_general_cs
col_name COLLATE latin1_bin LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_bin
```

If you want a column always to be treated in case-sensitive fashion, declare it with a case sensitive or binary collation. See Section 13.2.5, "CREATE TABLE Syntax".

Before MySQL 4.1, `COLLATE` is unavailable. Use the `BINARY` operator in expressions to treat a string as a binary string: `BINARY col_name LIKE 'a%'` or `col_name LIKE BINARY 'a%'`. In column declarations, use the `BINARY` attribute.

Simple comparison operations (`>=`, `>`, `=`, `<`, `<=`, sorting, and grouping) are based on each character's "sort value." Characters with the same sort value (such as 'E', 'e', and 'é') are treated as the same character.

A.5.2. Problems Using DATE Columns

The format of a `DATE` value is 'YYYY-MM-DD'. According to standard SQL, no other format is allowed. You should use this format in `UPDATE` expressions and in the `WHERE` clause of `SELECT` statements. For example:

```
mysql> SELECT * FROM tbl_name WHERE date >= '2003-05-05';
```

As a convenience, MySQL automatically converts a date to a number if the date is used in a numeric context (and vice versa). It is also smart enough to allow a "relaxed" string form when updating and in a `WHERE` clause that compares a date to a `TIMESTAMP`, `DATE`, or `DATETIME` column. ("Relaxed form" means that any punctuation character may be used as the separator between parts. For example, '2004-08-15' and '2004#08#15' are equivalent.) MySQL can also convert a string containing no separators (such as '20040815'), provided it makes sense as a date.

The special date '0000-00-00' can be stored and retrieved as '0000-00-00'. When using a '0000-00-00' date through MyODBC, it is automatically converted to `NULL` in MyODBC 2.50.12 and above, because ODBC can't handle this kind of date.

Because MySQL performs the conversions described above, the following statements work:

```
mysql> INSERT INTO tbl_name (idate) VALUES (19970505);
mysql> INSERT INTO tbl_name (idate) VALUES ('19970505');
mysql> INSERT INTO tbl_name (idate) VALUES ('97-05-05');
mysql> INSERT INTO tbl_name (idate) VALUES ('1997.05.05');
mysql> INSERT INTO tbl_name (idate) VALUES ('1997 05 05');
mysql> INSERT INTO tbl_name (idate) VALUES ('0000-00-00');

mysql> SELECT idate FROM tbl_name WHERE idate >= '1997-05-05';
mysql> SELECT idate FROM tbl_name WHERE idate >= 19970505;
mysql> SELECT MOD(idate,100) FROM tbl_name WHERE idate >= 19970505;
mysql> SELECT idate FROM tbl_name WHERE idate >= '19970505';
```

However, the following does not work:

```
mysql> SELECT idate FROM tbl_name WHERE STRCMP(idate,'20030505')=0;
```

`STRCMP()` is a string function, so it converts `idate` to a string in 'YYYY-MM-DD' format and performs a string comparison. It does not convert '20030505' to the date '2003-05-05' and perform a date comparison.

If you are using the `ALLOW_INVALID_DATES` SQL mode, MySQL allows you to store dates that are given only limited checking: MySQL ensures only that the day is in the range from 1 to 31 and the month is in the range from 1 to 12.

This makes MySQL very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation).

If you are not using the `NO_ZERO_IN_DATE` SQL mode, the day or month part can be zero. This is convenient if you want to store a birthdate in a `DATE` column and you know only part of the date.

If you are not using the `NO_ZERO_DATE` SQL mode, MySQL also allows you to store '0000-00-00' as a "dummy date." This is in some cases more convenient than using `NULL` values.

If the date cannot be converted to any reasonable value, a 0 is stored in the `DATE` column, which is retrieved as '0000-00-00'. This is both a speed and a convenience issue. We believe that the database server's responsibility is to retrieve the same date you stored (even if the data was not logically correct in all cases). We think it is up to the application and not the server to check the dates.

If you want MySQL to check all dates and accept only legal dates (unless overridden by `IGNORE`), you should set `sql_mode` to "`NO_ZERO_IN_DATE,NO_ZERO_DATE`".

Date handling in MySQL 5.0.1 and earlier works like MySQL 5.0.2 with the `ALLOW_INVALID_DATES` SQL mode enabled.

A.5.3. Problems with `NULL` Values

The concept of the `NULL` value is a common source of confusion for newcomers to SQL, who often think that `NULL` is the same thing as an empty string ''. This is not the case. For example, the following statements are completely different:

```
mysql> INSERT INTO my_table (phone) VALUES (NULL);
mysql> INSERT INTO my_table (phone) VALUES ('');
```

Both statements insert a value into the `phone` column, but the first inserts a `NULL` value and the second inserts an empty string. The meaning of the first can be regarded as "phone number is not known" and the meaning of the second can be regarded as "the person is known to have no phone, and thus no phone number."

To help with NULL handling, you can use the `IS NULL` and `IS NOT NULL` operators and the `IFNULL()` function.

In SQL, the NULL value is never true in comparison to any other value, even NULL. An expression that contains NULL always produces a NULL value unless otherwise indicated in the documentation for the operators and functions involved in the expression. All columns in the following example return NULL:

```
mysql> SELECT NULL, 1+NULL, CONCAT('Invisible',NULL);
```

If you want to search for column values that are NULL, you cannot use an `expr = NULL` test. The following statement returns no rows, because `expr = NULL` is never true for any expression:

```
mysql> SELECT * FROM my_table WHERE phone = NULL;
```

To look for NULL values, you must use the `IS NULL` test. The following statements show how to find the NULL phone number and the empty phone number:

```
mysql> SELECT * FROM my_table WHERE phone IS NULL;
mysql> SELECT * FROM my_table WHERE phone = '';
```

You can add an index on a column that can have NULL values if you are using MySQL 3.23.2 or newer and are using the MyISAM, InnoDB, or BDB storage engine. As of MySQL 4.0.2, the MEMORY storage engine also supports NULL values in indexes. Otherwise, you must declare an indexed column `NOT NULL` and you cannot insert NULL into the column.

When reading data with `LOAD DATA INFILE`, empty or missing columns are updated with `' '`. If you want a NULL value in a column, you should use `\N` in the data file. The literal word `''NULL''` may also be used under some circumstances. See Section 13.1.5, “`LOAD DATA INFILE` Syntax”.

When using `DISTINCT`, `GROUP BY`, or `ORDER BY`, all NULL values are regarded as equal.

When using `ORDER BY`, NULL values are presented first, or last if you specify `DESC` to sort in descending order. Exception: In MySQL 4.0.2 through 4.0.10, NULL values sort first regardless of sort order.

Aggregate (summary) functions such as `COUNT()`, `MIN()`, and `SUM()` ignore NULL values. The exception to this is `COUNT(*)`, which counts rows and not individual column values. For example, the following statement produces two counts. The first is a count of the number of rows in the table, and the second is a count of the number of non-NULL values in the `age` column:

```
mysql> SELECT COUNT(*), COUNT(age) FROM person;
```

For some column types, MySQL handles NULL values specially. If you insert NULL into a `TIMESTAMP` column, the current date and time is inserted. If you insert NULL into an integer column that has the `AUTO_INCREMENT` attribute, the next number in the sequence is inserted.

A.5.4. Problems with Column Aliases

You can use an alias to refer to a column in `GROUP BY`, `ORDER BY`, or `HAVING` clauses. Aliases can also be used to give columns better names:

```
SELECT SQRT(a*b) AS root FROM tbl_name GROUP BY root HAVING root > 0;
SELECT id, COUNT(*) AS cnt FROM tbl_name GROUP BY id HAVING cnt > 0;
SELECT id AS 'Customer identity' FROM tbl_name;
```

Standard SQL doesn't allow you to refer to a column alias in a `WHERE` clause. This is because when the `WHERE` code is executed, the column value may not yet be determined. For example, the following query is illegal:

```
SELECT id, COUNT(*) AS cnt FROM tbl_name WHERE cnt > 0 GROUP BY id;
```

The WHERE statement is executed to determine which rows should be included in the GROUP BY part, whereas HAVING is used to decide which rows from the result set should be used.

A.5.5. Rollback Failure for Non-Transactional Tables

If you receive the following message when trying to perform a ROLLBACK, it means that one or more of the tables you used in the transaction do not support transactions:

```
Warning: Some non-transactional changed tables couldn't be rolled back
```

These non-transactional tables are not affected by the ROLLBACK statement.

If you were not deliberately mixing transactional and non-transactional tables within the transaction, the most likely cause for this message is that a table you thought was transactional actually is not. This can happen if you try to create a table using a transactional storage engine that is not supported by your **mysqld** server (or that was disabled with a startup option). If **mysqld** doesn't support a storage engine, it instead creates the table as a MyISAM table, which is non-transactional.

You can check the table type for a table by using either of these statements:

```
SHOW TABLE STATUS LIKE 'tbl_name';
SHOW CREATE TABLE tbl_name;
```

See Section 13.5.4.17, “SHOW TABLE STATUS Syntax” and Section 13.5.4.5, “SHOW CREATE TABLE Syntax”.

You can check which storage engines your **mysqld** server supports by using this statement:

```
SHOW ENGINES;
```

Before MySQL 4.1.2, SHOW ENGINES is unavailable. Use the following statement instead and check the value of the variable that is associated with the storage engine in which you are interested:

```
SHOW VARIABLES LIKE 'have_%';
```

For example, to determine whether the InnoDB storage engine is available, check the value of the have_innodb variable.

See Section 13.5.4.8, “SHOW ENGINES Syntax” and Section 13.5.4.19, “SHOW VARIABLES Syntax”.

A.5.6. Deleting Rows from Related Tables

MySQL does not support subqueries prior to Version 4.1, or the use of more than one table in the DELETE statement prior to Version 4.0. If your version of MySQL does not support subqueries or multiple-table DELETE statements, you can use the following approach to delete rows from two related tables:

1. SELECT the rows based on some WHERE condition in the main table.
2. DELETE the rows in the main table based on the same condition.
3. DELETE FROM related_table WHERE related_column IN (selected_rows).

If the total length of the `DELETE` statement for `related_table` is more than 1MB (the default value of the `max_allowed_packet` system variable), you should split it into smaller parts and execute multiple `DELETE` statements. You probably get the fastest `DELETE` by specifying only 100 to 1,000 `related_column` values per statement if the `related_column` is indexed. If the `related_column` isn't indexed, the speed is independent of the number of arguments in the `IN` clause.

A.5.7. Solving Problems with No Matching Rows

If you have a complicated query that uses many tables but that doesn't return any rows, you should use the following procedure to find out what is wrong:

1. Test the query with `EXPLAIN` to check whether you can find something that is obviously wrong. See Section 7.2.1, “`EXPLAIN` Syntax (Get Information About a `SELECT`)”.
2. Select only those columns that are used in the `WHERE` clause.
3. Remove one table at a time from the query until it returns some rows. If the tables are large, it's a good idea to use `LIMIT 10` with the query.
4. Issue a `SELECT` for the column that should have matched a row against the table that was last removed from the query.
5. If you are comparing `FLOAT` or `DOUBLE` columns with numbers that have decimals, you can't use equality (`=`) comparisons. This problem is common in most computer languages because not all floating-point values can be stored with exact precision. In some cases, changing the `FLOAT` to a `DOUBLE` fixes this. See Section A.5.8, “Problems with Floating-Point Comparisons”.
6. If you still can't figure out what's wrong, create a minimal test that can be run with `mysql test < query.sql` that shows your problems. You can create a test file by dumping the tables with `mysqldump --quick db_name tbl_name_1 ... tbl_name_n > query.sql`. Open the file in an editor, remove some insert lines (if there are more than needed to demonstrate the problem), and add your `SELECT` statement at the end of the file.

Verify that the test file demonstrates the problem by executing these commands:

```
shell> mysqladmin create test2
shell> mysql test2 < query.sql
```

Post the test file using `mysqlbug` to the general MySQL mailing list. See Section 1.6.1.1, “The MySQL Mailing Lists”.

A.5.8. Problems with Floating-Point Comparisons

Note that the following section is relevant primarily for versions of MySQL older than 5.0.3. As of version 5.0.3, MySQL performs `DECIMAL` operations with a precision of 64 decimal digits, which should solve most common inaccuracy problems when it comes to `DECIMAL` columns. For `DOUBLE` and `FLOAT` columns, the problems remain because inexactness is the basic nature of floating point numbers.

Floating-point numbers sometimes cause confusion because they are not stored as exact values inside computer architecture. What you can see on the screen usually is not the exact value of the number. The column types `FLOAT`, `DOUBLE`, and `DECIMAL` are such. `DECIMAL` columns store values with exact precision because they are represented as strings, but calculations on `DECIMAL` values before MySQL 5.0.3 are done using floating-point operations.

The following example (for older MySQL version than 5.0.3) demonstrate the problem. It shows that even for the `DECIMAL` column type, calculations that are done using floating-point operations

are subject to floating-point error. (In all MySQL versions, you would have similar problems if you would replace the DECIMAL columns with FLOAT).

```
mysql> CREATE TABLE t1 (i INT, d1 DECIMAL(9,2), d2 DECIMAL(9,2));
mysql> INSERT INTO t1 VALUES (1, 101.40, 21.40), (1, -80.00, 0.00),
-> (2, 0.00, 0.00), (2, -13.20, 0.00), (2, 59.60, 46.40),
-> (2, 30.40, 30.40), (3, 37.00, 7.40), (3, -29.60, 0.00),
-> (4, 60.00, 15.40), (4, -10.60, 0.00), (4, -34.00, 0.00),
-> (5, 33.00, 0.00), (5, -25.80, 0.00), (5, 0.00, 7.20),
-> (6, 0.00, 0.00), (6, -51.40, 0.00);
```

```
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b
-> FROM t1 GROUP BY i HAVING a <> b;
```

i	a	b
1	21.40	21.40
2	76.80	76.80
3	7.40	7.40
4	15.40	15.40
5	7.20	7.20
6	-51.40	0.00

The result is correct. Although the first five records look like they shouldn't pass the comparison test (the values of a and b do not appear to be different), they may do so because the difference between the numbers shows up around the tenth decimal or so, depending on computer architecture.

As of MySQL 5.0.3, you will get only the last row in the above result.

The problem cannot be solved by using ROUND() or similar functions, because the result is still a floating-point number:

```
mysql> SELECT i, ROUND(SUM(d1), 2) AS a, ROUND(SUM(d2), 2) AS b
-> FROM t1 GROUP BY i HAVING a <> b;
```

i	a	b
1	21.40	21.40
2	76.80	76.80
3	7.40	7.40
4	15.40	15.40
5	7.20	7.20
6	-51.40	0.00

This is what the numbers in column a look like when displayed with more decimal places:

```
mysql> SELECT i, ROUND(SUM(d1), 2)*1.0000000000000000 AS a,
-> ROUND(SUM(d2), 2) AS b FROM t1 GROUP BY i HAVING a <> b;
```

i	a	b
1	21.3999999999999986	21.40
2	76.7999999999999972	76.80
3	7.4000000000000004	7.40
4	15.4000000000000004	15.40
5	7.2000000000000002	7.20
6	-51.3999999999999986	0.00

Depending on your computer architecture, you may or may not see similar results. Different CPUs may evaluate floating-point numbers differently. For example, on some machines you may get the "correct" results by multiplying both arguments by 1, as the following example shows.

Warning: Never use this method in your applications. It is not an example of a trustworthy method!

```
mysql> SELECT i, ROUND(SUM(d1), 2)*1 AS a, ROUND(SUM(d2), 2)*1 AS b
-> FROM t1 GROUP BY i HAVING a <> b;
```

i	a	b
6	-51.40	0.00

The reason that the preceding example seems to work is that on the particular machine where the test was done, CPU floating-point arithmetic happens to round the numbers to the same value. However, there is no rule that any CPU should do so, so this method cannot be trusted.

The correct way to do floating-point number comparison is to first decide on an acceptable tolerance for differences between the numbers and then do the comparison against the tolerance value. For example, if we agree that floating-point numbers should be regarded the same if they are same within a precision of one in ten thousand (0.0001), the comparison should be written to find differences larger than the tolerance value:

```
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
-> GROUP BY i HAVING ABS(a - b) > 0.0001;
```

i	a	b
6	-51.40	0.00

1 row in set (0.00 sec)

Conversely, to get rows where the numbers are the same, the test should find differences within the tolerance value:

```
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
-> GROUP BY i HAVING ABS(a - b) <= 0.0001;
```

i	a	b
1	21.40	21.40
2	76.80	76.80
3	7.40	7.40
4	15.40	15.40
5	7.20	7.20

A.6. Optimizer-Related Issues

MySQL uses a cost-based optimizer to determine the best way to resolve a query. In many cases, MySQL can calculate the best possible query plan, but sometimes MySQL doesn't have enough information about the data at hand and has to make "educated" guesses about the data.

For the cases when MySQL does not do the "right" thing, tools that you have available to help MySQL are:

- Use the `EXPLAIN` statement to get information about how MySQL processes a query. To use it, just add the keyword `EXPLAIN` to the front of your `SELECT` statement:

```
mysql> EXPLAIN SELECT * FROM t1, t2 WHERE t1.i = t2.i;
```

`EXPLAIN` is discussed in more detail in Section 7.2.1, "EXPLAIN Syntax (Get Information About a SELECT)".

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See

Section 13.5.2.1, “ANALYZE TABLE Syntax”.

- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index. See Section 13.1.7, “SELECT Syntax”.

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
WHERE t1.col_name=t2.col_name;
```

`USE INDEX` and `IGNORE INDEX` may also be useful.

- Global and table-level `STRAIGHT_JOIN`. See Section 13.1.7, “SELECT Syntax”.
- You can tune global or thread-specific system variables. For example, Start **mysqld** with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.3.3, “Server System Variables”.

A.7. Table Definition-Related Issues

A.7.1. Problems with ALTER TABLE

`ALTER TABLE` changes a table to the current character set. If you get a duplicate-key error during `ALTER TABLE`, the cause is either that the new character sets maps two keys to the same value or that the table is corrupted. In the latter case, you should run `REPAIR TABLE` on the table.

If `ALTER TABLE` dies with the following error, the problem may be that MySQL crashed during an earlier `ALTER TABLE` operation and there is an old table named `A-xxx` or `B-xxx` lying around:

```
Error on rename of './database/name.frm'
to './database/B-xxx.frm' (Errcode: 17)
```

In this case, go to the MySQL data directory and delete all files that have names starting with `A-` or `B-`. (You may want to move them elsewhere instead of deleting them.)

`ALTER TABLE` works in the following way:

- Create a new table named `A-xxx` with the requested structural changes.
- Copy all rows from the original table to `A-xxx`.
- Rename the original table to `B-xxx`.
- Rename `A-xxx` to your original table name.
- Delete `B-xxx`.

If something goes wrong with the renaming operation, MySQL tries to undo the changes. If something goes seriously wrong (although this shouldn't happen), MySQL may leave the old table as `B-xxx`. A simple rename of the table files at the system level should get your data back.

If you use `ALTER TABLE` on a transactional table or if you are using Windows or OS/2, `ALTER TABLE` unlocks the table if you had done a `LOCK TABLE` on it. This is because InnoDB and these operating systems cannot drop a table that is in use.

A.7.2. How to Change the Order of Columns in a Table

First, consider whether you really need to change the column order in a table. The whole point of SQL is to abstract the application from the data storage format. You should always specify the order in which you wish to retrieve your data. The first of the following statements returns columns in the order `col_name1, col_name2, col_name3`, whereas the second returns them in the order `col_name1, col_name3, col_name2`:

```
mysql> SELECT col_name1, col_name2, col_name3 FROM tbl_name;
mysql> SELECT col_name1, col_name3, col_name2 FROM tbl_name;
```

If you decide to change the order of table columns anyway, you can do so as follows:

1. Create a new table with the columns in the new order.
2. Execute this statement:

```
mysql> INSERT INTO new_table
      -> SELECT columns-in-new-order FROM old_table;
```

3. Drop or rename `old_table`.
4. Rename the new table to the original name:

```
mysql> ALTER TABLE new_table RENAME old_table;
```

`SELECT *` is quite suitable for testing queries. However, in an application, you should *never* rely on using `SELECT *` and retrieving the columns based on their position. The order and position in which columns are returned does not remain the same if you add, move, or delete columns. A simple change to your table structure could cause your application to fail.

A.7.3. TEMPORARY TABLE Problems

The following list indicates limitations on the use of TEMPORARY tables:

- A TEMPORARY table can only be of type HEAP, ISAM, MyISAM, MERGE, or InnoDB.
- You cannot refer to a TEMPORARY table more than once in the same query. For example, the following does not work:

```
mysql> SELECT * FROM temp_table, temp_table AS t2;
ERROR 1137: Can't reopen table: 'temp_table'
```

- The `SHOW TABLES` statement does not list TEMPORARY tables.
- You cannot use `RENAME` to rename a TEMPORARY table. However, you can use `ALTER TABLE` instead:

```
mysql> ALTER TABLE orig_name RENAME new_name;
```

Appendix B. Credits

This appendix lists the developers, contributors, and supporters that have helped to make MySQL what it is today.

B.1. Developers at MySQL AB

These are the developers that are or have been employed by MySQL AB to work on the MySQL database software, roughly in the order they started to work with us. Following each developer is a small list of the tasks that the developer is responsible for, or the accomplishments they have made. All developers are involved in support.

- Michael (Monty) Widenius
 - Lead developer and main author of the MySQL server (**mysqld**).
 - New functions for the string library.
 - Most of the `mysys` library.
 - The `ISAM` and `MyISAM` libraries (B-tree index file handlers with index compression and different record formats).
 - The `HEAP` library. A memory table system with our superior full dynamic hashing. In use since 1981 and published around 1984.
 - The **replace** program (take a look at it, it's **COOL!**).
 - Connector/ODBC (MyODBC), the ODBC driver for Windows.
 - Fixing bugs in MIT-pthreads to get it to work for MySQL Server. And also Unireg, a curses-based application tool with many utilities.
 - Porting of `mSQL` tools like `msqlperl`, `DBD/DBI`, and `DB2mysql`.
 - Most of `crash-me` and the foundation for the MySQL benchmarks.
- David Axmark
 - Initial main writer of the **Reference Manual**, including enhancements to **texi2html**.
 - Automatic Web site updating from the manual.
 - Initial Autoconf, Automake, and Libtool support.
 - Licensing.
 - Parts of all the text files. (Nowadays only the `README` is left. The rest ended up in the manual.)
 - Lots of testing of new features.
 - Our in-house Free Software legal expert.
 - Mailing list maintainer (who never has the time to do it right...).
 - Our original portability code (now more than 10 years old). Nowadays only some parts of `mysys` are left.
 - Someone for Monty to call in the middle of the night when he just got that new feature to work.

- Chief "Open Sourcerer" (MySQL community relations).
- Jani Tolonen
 - **mysqlimport**
 - A lot of extensions to the command-line clients.
 - `PROCEDURE ANALYSE()`
- Sinisa Milivojevic
 - Compression (with `zlib`) in the client/server protocol.
 - Perfect hashing for the lexical analyzer phase.
 - Multi-row `INSERT`
 - **mysqldump** -e option
 - `LOAD DATA LOCAL INFILE`
 - `SQL_CALC_FOUND_ROWS SELECT` option
 - `--max-user-connections=...` option
 - `net_read` and `net_write_timeout`
 - `GRANT/REVOKE` and `SHOW GRANTS FOR`
 - New client/server protocol for 4.0
 - `UNION` in 4.0
 - Multiple-table `DELETE/UPDATE`
 - Derived tables in 4.1
 - User resources management
 - Initial developer of the MySQL++ C++ API and the MySQLGUI client.
- Tonu Samuel (past developer)
 - VIO interface (the foundation for the encrypted client/server protocol).
 - MySQL Filesystem (a way to use MySQL databases as files and directories).
 - The `CASE` expression.
 - The `MD5()` and `COALESCE()` functions.
 - RAID support for MyISAM tables.
- Sasha Pachev
 - Initial implementation of replication (up to version 4.0).
 - `SHOW CREATE TABLE`.
 - `mysql-bench`
- Matt Wagner

- MySQL test suite.
- Webmaster (until 2002).
- Coordinator of development.
- Miguel Solorzano
 - Win32 development and release builds.
 - Windows NT server code.
 - WinMySQLAdmin
- Timothy Smith (past developer)
 - Dynamic character sets support.
 - configure, RPMs and other parts of the build system.
 - Initial developer of `libmysqld`, the embedded server.
- Sergei Golubchik
 - Full-text search.
 - Added keys to the MERGE library.
- Jeremy Cole
 - Proofreading and editing this fine manual.
 - `ALTER TABLE ... ORDER BY ...`
 - `UPDATE ... ORDER BY ...`
 - `DELETE ... ORDER BY ...`
- Indrek Siitan
 - Designing/programming of our Web interface.
 - Author of our newsletter management system.
- Jorge del Conde
 - **MySQLCC (MySQL Control Center)**
 - Win32 development
 - Initial implementation of the Web site portals.
- Venu Anuganti
 - MyODBC 3.51
 - New client/server protocol for 4.1 (for prepared statements).
- Arjen Lentz
 - Maintainer of the MySQL Reference Manual.
 - Preparing the O'Reilly printed edition of the manual.

- Alexander (Bar) Barkov, Alexey (Holyfoot) Botchkov, and Ramil Kalimullin
 - Spatial data (GIS) and R-Trees implementation for 4.1
 - Unicode and character sets for 4.1; documentation for same
- Oleksandr (Sanja) Byelkin
 - Query cache in 4.0
 - Implementation of subqueries (4.1).
- Aleksey (Walrus) Kishkin and Alexey (Ranger) Stroganov
 - Benchmarks design and analysis.
 - Maintenance of the MySQL test suite.
- Zak Greant
 - Open Source advocate, MySQL community relations.
- Carsten Pedersen
 - The MySQL Certification program.
- Lenz Grimmer
 - Production (build and release) engineering.
- Peter Zaitsev
 - SHA1 (), AES_ENCRYPT () and AES_DECRYPT () functions.
 - Debugging, cleaning up various features.
- Alexander (Salle) Keremidarski
 - Support.
 - Debugging.
- Per-Erik Martin
 - Lead developer for stored procedures (5.0) and triggers.
- Jim Winstead
 - Lead Web developer.
- Mark Matthews
 - Connector/J driver (Java).
- Peter Gultzan
 - SQL standards compliance.
 - Documentation of existing MySQL code/algorithms.
 - Character set documentation.
- Guilhem Bichot
 - Replication, from MySQL version 4.0.

- Fixed handling of exponents for `DECIMAL`.
- Author of `mysql_tableinfo`.
- Antony T. Curtis
 - Porting of the MySQL Database software to OS/2.
- Mikael Ronstrom
 - Much of the initial work on NDB Cluster until 2000. Roughly half the code base at that time. Transaction protocol, node recovery, system restart and restart code and parts of the API functionality.
 - Lead Architect, developer, debugger of NDB Cluster 1994-2004
 - Lots of optimizations
- Jonas Orelund
 - On-line Backup
 - The automatic test environment of MySQL Cluster
 - Portability Library for NDB Cluster
 - Lots of other things
- Pekka Nousiainen
 - Ordered index implementation of MySQL Cluster
 - BLOB support in MySQL Cluster
 - Charset support in MySQL Cluster
- Martin Skold
 - Unique index implementation of MySQL Cluster
 - Integration of NDB Cluster into MySQL
- Magnus Svensson
 - The test framework for MySQL Cluster
 - Integration of NDB Cluster into MySQL
- Tomas Ulin
 - Lots of work on configuration changes for simple installation and use of MySQL Cluster

B.2. Contributors to MySQL

While MySQL AB owns all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize those who have made contributions of one kind or another to the `MySQL distribution`. Contributors are listed here, in somewhat random order:

- Gianmassimo Vigazzola <qwerg@mbx.vol.it> or <qwerg@tin.it>

The initial port to Win32/NT.

- Per Eric Olsson
For more or less constructive criticism and real testing of the dynamic record format.
- Irena Pancirov <irena@mail.yacc.it>
Win32 port with Borland compiler. `mysqlshutdown.exe` and `mysqlwatch.exe`
- David J. Hughes
For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with mSQL, but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. **mysqladmin** and **mysql** client are programs that were largely influenced by their mSQL counterparts. We have put a lot of effort into making the MySQL syntax a superset of mSQL. Many of the API's ideas are borrowed from mSQL to make it easy to port free mSQL programs to the MySQL API. The MySQL software doesn't contain any code from mSQL. Two files in the distribution (`client/insert_test.c` and `client/select_test.c`) are based on the corresponding (non-copyrighted) files in the mSQL distribution, but are modified as examples showing the changes necessary to convert code from mSQL to MySQL Server. (mSQL is copyrighted David J. Hughes.)
- Patrick Lynch
For helping us acquire <http://www.mysql.com/>.
- Fred Lindberg
For setting up gmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.
- Igor Romanenko <igor@frog.kiev.ua>
mysqldump (previously `msqldump`, but ported and enhanced by Monty).
- Yuri Dario
For keeping up and extending the MySQL OS/2 port.
- Tim Bunce
Author of **mysqlhotcopy**.
- Zarko Mocnik <zarko.mocnik@dem.si>
Sorting for Slovenian language.
- "TAMITO" <tommy@valley.ne.jp>
The `_MB` character set macros and the `ujis` and `sjis` character sets.
- Joshua Chamas <joshua@chamas.com>
Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.
- Yves Carlier <Yves.Carlier@rug.ac.be>
mysqlaccess, a program to show the access rights for a user.
- Rhys Jones <rhys@wales.com> (And GWE Technologies Limited)
For one of the early JDBC drivers.
- Dr Xiaokun Kelvin ZHU <X.Zhu@brad.ac.uk>

Further development of one of the early JDBC drivers and other MySQL-related Java tools.

- James Cooper <pixel@organic.com>
For setting up a searchable mailing list archive at his site.
- Rick Mehalick <Rick_Mehalick@i-o.com>
For `xmysql`, a graphical X client for MySQL Server.
- Doug Sisk <sisk@wix.com>
For providing RPM packages of MySQL for Red Hat Linux.
- Diemand Alexander V. <axeld@vial.ethz.ch>
For providing RPM packages of MySQL for Red Hat Linux-Alpha.
- Antoni Pamies Olive <toni@readysoft.es>
For providing RPM versions of a lot of MySQL clients for Intel and SPARC.
- Jay Bloodworth <jay@pathways.sde.state.sc.us>
For providing RPM versions for MySQL 3.21.
- David Sacerdote <davids@secnet.com>
Ideas for secure checking of DNS hostnames.
- Wei-Jou Chen <jou@nematic.ieo.nctu.edu.tw>
Some support for Chinese(BIG5) characters.
- Wei He <hewei@mail.ied.ac.cn>
A lot of functionality for the Chinese(GBK) character set.
- Jan Pazdziora <adelton@fi.muni.cz>
Czech sorting order.
- Zeev Suraski <bourbon@netvision.net.il>
`FROM_UNIXTIME()` time formatting, `ENCRYPT()` functions, and **bison** advisor. Active mailing list member.
- Luuk de Boer <luuk@wxs.nl>
Ported (and extended) the benchmark suite to DBI/DBD. Have been of great help with crash-me and running benchmarks. Some new date functions. The **mysql_setpermission** script.
- Alexis Mikhailov <root@medinf.chuvashia.su>
User-defined functions (UDFs); `CREATE FUNCTION` and `DROP FUNCTION`.
- Andreas F. Bobak <bobak@relog.ch>
The `AGGREGATE` extension to user-defined functions.
- Ross Wakelin <R.Wakelin@march.co.uk>
Help to set up InstallShield for MySQL-Win32.

- Jethro Wright III <jetman@li.net>
The libmysql.dll library.
- James Pereria <jpereira@iafrica.com>
Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.
- Curt Sampson <cjs@portal.ca>
Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.
- Martin Ramsch <m.ramsch@computer.org>
Examples in the MySQL Tutorial.
- Steve Harvey
For making **mysqlaccess** more secure.
- Konark IA-64 Centre of Persistent Systems Private Limited
<http://www.pspl.co.in/konark/>. Help with the Win64 port of the MySQL server.
- Albert Chin-A-Young.
Configure updates for Tru64, large file support and better TCP wrappers support.
- John Birrell
Emulation of pthread_mutex() for OS/2.
- Benjamin Pflugmann
Extended MERGE tables to handle INSERTS. Active member on the MySQL mailing lists.
- Jocelyn Fournier
Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).
- Marc Liyanage
Maintaining the Mac OS X packages and providing invaluable feedback on how to create Mac OS X PKGs.
- Robert Rutherford
Providing invaluable information and feedback about the QNX port.
- Previous developers of NDB Cluster
Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Atallah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, <jehamby@lightside>, <psmith@BayNetworks.com>, <duane@connect.com.au>, Ted Deppner

<ted@psyber.com>, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

- Daniel Koch <dkoch@amcity.com>
Irix setup.
- Luuk de Boer <luuk@wxs.nl>
Benchmark questions.
- Tim Sailer <tps@users.buoy.com>
DBD::mysql questions.
- Boyd Lynn Gerber <gerberb@zenez.com>
SCO-related questions.
- Richard Mehalick <RM186061@shellus.com>
xmysql-related questions and basic installation questions.
- Zeev Suraski <bourbon@netvision.net.il>
Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.
- Francesc Guasch <frankie@citel.upc.es>
General questions.
- Jonathan J Smith <jsmith@wtp.net>
Questions pertaining to OS-specifics with Linux, SQL syntax, and other things that might need some work.
- David Sklar <sklar@student.net>
Using MySQL from PHP and Perl.
- Alistair MacDonald <A.MacDonald@uel.ac.uk>
Not yet specified, but is flexible and can handle Linux and maybe HP-UX. tries to get user to use **mysqlbug**.
- John Lyon <jlyon@imag.net>
Questions about installing MySQL on Linux systems, using either .rpm files or compiling from source.
- Lorvid Ltd. <lorvid@WOLFENET.com>
Simple billing/license/support/copyright issues.
- Patrick Sherrill <patrick@coconet.com>
ODBC and VisualC++ interface questions.
- Randy Harmon <rjharmon@uptimecomputers.com>
DBD, Linux, some SQL syntax questions.

B.3. Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Paul DuBois
Ongoing help with making this manual correct and understandable. That includes rewriting Monty's and David's attempts at English into English as other people know it.
- Kim Aldale
Helped to rewrite Monty's and David's early attempts at English into English.
- Michael J. Miller Jr. <mke@terrapin.turbolift.com>
For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).
- Yan Cailin
First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded (<http://mysql.hitstar.com/>) versions were based. Personal home page at linuxdb.yeah.net [<http://linuxdb.yeah.net>].
- Jay Flaherty <fty@mediapulse.com>
Big parts of the Perl DBI/DBD section in the manual.
- Paul Southworth <pauls@etext.org>, Ray Loyzaga <yar@cs.su.oz.au>
Proof-reading of the Reference Manual.
- Therrien Gilbert <gilbert@ican.net>, Jean-Marc Pouyot <jmp@scalaire.fr>
French error messages.
- Petr Snajdr, <snajdr@pvt.net>
Czech error messages.
- Jaroslaw Lewandowski <jotel@itnet.com.pl>
Polish error messages.
- Miguel Angel Fernandez Roiz
Spanish error messages.
- Roy-Magne Mo <rmo@www.hivolda.no>
Norwegian error messages and testing of MySQL 3.21.xx.
- Timur I. Bakeyev <root@timur.tatarstan.ru>
Russian error messages.
- <brenno@dewinter.com> & Filippo Grassilli <phil@hyppo.com>
Italian error messages.
- Dirk Munzinger <dirk@trinity.saar.de>

German error messages.

- Billik Stefan <billik@sun.uniag.sk>

Slovak error messages.

- Stefan Saroiu <tzoompy@cs.washington.edu>

Romanian error messages.

- Peter Feher

Hungarian error messages.

- Roberto M. Serqueira

Portuguese error messages.

- Carsten H. Pedersen

Danish error messages.

- Arjen G. Lentz

Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

B.4. Libraries used by and included with MySQL

The following is a list of the creators of the libraries we have included with the MySQL server source to make it easy to compile and install MySQL. We are very thankful to all individuals that have created these and it has made our life much easier.

- Fred Fish

For his excellent C debugging and trace library. Monty has made a number of smaller improvements to the library (speed and additional options).

- Richard A. O'Keefe

For his public domain string library.

- Henry Spencer

For his regex library, used in `WHERE column REGEXP regexp`.

- Chris Provenzano

Portable user level pthreads. From the copyright: This product includes software developed by Chris Provenzano, the University of California, Berkeley, and contributors. We are currently using version 1_60_beta6 patched by Monty (see `mit-pthreads/Changes-mysql`).

- Jean-loup Gailly and Mark Adler

For the zlib library (used on MySQL on Windows).

- Bjorn Benson

For his `safe_malloc` (memory checker) package which is used in when you configure MySQL with `--debug`.

- Free Software Foundation

The `readline` library (used by the **mysql** command-line client).

- The NetBSD foundation

The `libedit` package (optionally used by the **mysql** command-line client).

B.5. Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We can't list every possible package here because the list would then be way to hard to maintain. For other packages, please refer to the software portal at <http://solutions.mysql.com/software/>.

- Tim Bunce, Alligator Descartes

For the DBD (Perl) interface.

- Andreas Koenig <a.koenig@mind.de>

For the Perl interface for MySQL Server.

- Jochen Wiedmann <wiedmann@neckar-alb.de>

For maintaining the Perl DBD : :mysql module.

- Eugene Chan <eugene@acenet.com.sg>

For porting PHP for MySQL Server.

- Georg Richter

MySQL 4.1 testing and bug hunting. New PHP 5.0 `mysql_i` extension (API) for use with MySQL 4.1 and up.

- Giovanni Maruzzelli <maruzz@matrice.it>

For porting iODBC (Unix ODBC).

- Xavier Leroy <Xavier.Leroy@inria.fr>

The author of LinuxThreads (used by the MySQL Server on Linux).

B.6. Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- Free Software Foundation

From whom we got an excellent compiler (**gcc**), an excellent debugger (**gdb** and the `libc` lib-

rary (from which we have borrowed `strtoc` to get some code working in Linux).

- Free Software Foundation & The XEmacs development team

For a really great editor/environment used by almost everybody at MySQL AB.

- Julian Seward

Author of `valgrind`, an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

- Dorothea Lütkehaus and Andreas Zeller

For DDD (The Data Display Debugger) which is an excellent graphical frontend to **gdb**).

B.7. Supporters of MySQL

While MySQL AB owns all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize the following companies, which helped us finance the development of the `MySQL server`, such as by paying us for developing a new feature or giving us hardware for development of the `MySQL server`.

- VA Linux / Andover.net

Funded replication.

- NuSphere

Editing of the MySQL manual.

- Stork Design studio

The MySQL Web site in use between 1998-2000.

- Intel

Contributed to development on Windows and Linux platforms.

- Compaq

Contributed to Development on Linux/Alpha.

- SWSoft

Development on the embedded **mysqld** version.

- FutureQuest

`--skip-show-database`

Appendix C. MySQL and the Future (the TODO)

This section summarizes the features that we plan to implement in MySQL Server. The items are ordered by release series. Within a list, items are shown in approximately the order they will be done.

Note: If you are an enterprise-level user with an urgent need for a particular feature, please contact <sales@mysql.com> to discuss sponsoring options. Targeted financing by sponsor companies allows us to allocate additional resources for specific purposes. One example of a feature sponsored in the past is replication.

C.1. New Features Planned for 5.0

The following features are planned for inclusion into MySQL 5.0. Some of the features such as stored procedures and true VARCHAR are complete and are included in MySQL 5.0 alpha. Others such as cursors are only partially available. Expect these and other features to mature and be fully supported in upcoming releases.

Note that because we have many developers that are working on different projects, there will also be many additional features. There is also a small chance that some of these features will be added to MySQL 4.1. For a list what is done in MySQL 4.1, see Section 1.5.2.1, “Features Available in MySQL 4.1”.

For those wishing to take a look at the bleeding edge of MySQL development, we make our Bit-Keeper repository for MySQL version 5.0 publicly available. See Section 2.8.3, “Installing from the Development Source Tree”.

- Views
 - Views, implemented in stepwise fashion up to full functionality. See Section 1.7.5.6, “Views”. See Section 21.2, “CREATE VIEW Syntax”.
- Stored Procedures
 - Stored procedures currently are implemented, based on the SQL:2003 standard. See Chapter 19, *Stored Procedures and Functions*.
- New functionality
 - Elementary cursor support. See Section 19.2.11, “Cursors”.
 - The ability to specify explicitly for MyISAM tables that an index should be created as an RTREE index. (In MySQL 4.1, RTREE indexes are used internally for geometrical data that use GIS data types, but cannot be created on request.)
 - BIT data type for holding bit-field values.
- Standards compliance, portability and migration
 - Support for Data Dictionary / INFORMATION_SCHEMA. See Chapter 22, *The INFORMATION_SCHEMA Information Database*.
 - Add true VARCHAR support (column lengths longer than 255, and no stripping of trailing whitespace).
- Speed enhancements
 - SHOW COLUMNS FROM *tbl_name* (used by the **mysql** client to allow expansions of

column names) should not open the table, only the definition file. This requires less memory and will be much faster.

- Allow `DELETE` on `MyISAM` tables to use the record cache. To do this, we need to update the threads record cache when we update the `.MYD` file.
- Better support for `MEMORY` tables:
 - Dynamic length rows.
 - Faster row handling (less copying).
- Usability enhancements
 - Resolving the issue of `RENAME TABLE` on a table used in an active `MERGE` table possibly corrupting the table.

The news section of this manual includes a more in-depth list of features. See Section D.1, “Changes in release 5.0.x (Development)”.

C.2. New Features Planned for 5.1

- New functionality
 - `FOREIGN KEY` support for all table types, not just `InnoDB`.
 - Column-level constraints. See Section 1.7.6, “How MySQL Deals with Constraints”.
 - Online backup with very low performance penalty. The online backup will make it easy to add a new replication slave without taking down the master.
- Speed enhancements
 - New text based table definition file format (`.frm` files) and a table cache for table definitions. This enables us to do faster queries of table structures and do more efficient foreign key support.
- Usability enhancements
 - Add options to the client/server protocol to get progress notes for long running commands.
 - Implement `RENAME DATABASE`. To make this safe for all storage engines, it should work as follows:
 1. Create the new database.
 2. For every table, do a rename of the table to another database, as we do with the `RENAME` command.
 3. Drop the old database.
 - New internal file interface change. This makes all file handling much more general and makes it easier to add extensions.

C.3. New Features Planned for the Near Future

- New functionality
 - Oracle-like `CONNECT BY PRIOR` to search tree-like (hierarchical) structures.
 - Add all missing standard SQL and ODBC 3.0 types.
 - `INSERT SQL_CONCURRENT` and `mysql --concurrent-insert` to do a concurrent insert at the end of a table if the table is read-locked.
 - Allow variables to be updated in `UPDATE` statements. For example: `UPDATE foo SET @a:=a+b, a=@a, b=@a+c.`
 - Change when user variables are updated so that you can use them with `GROUP BY`, as in the following statement: `SELECT id, @a:=COUNT(*), SUM(sum_col)/@a FROM tbl_name GROUP BY id.`
 - Add an `IMAGE` option to `LOAD DATA INFILE` to not update `TIMESTAMP` and `AUTO_INCREMENT` columns.
 - Add `LOAD DATA INFILE ... UPDATE` syntax that works like this:
 - For tables with primary keys, if an input record contains a primary key value, existing rows matching that primary key value are updated from the remainder of the input columns. However, columns corresponding to columns that are *missing* from the input record are not touched.
 - For tables with primary keys, if an input record does not contain the primary key value or is missing some part of the key, the record is treated as `LOAD DATA INFILE ... REPLACE INTO.`
 - Make `LOAD DATA INFILE` understand syntax like this:

```
LOAD DATA INFILE 'file_name.txt' INTO TABLE tbl_name
  TEXT_FIELDS (text_col1, text_col2, text_col3)
  SET table_col1=CONCAT(text_col1, text_col2),
      table_col3=23
  IGNORE text_col3
```

This can be used to skip over extra columns in the text file, or update columns based on expressions of the read data.
- New functions for working with `SET` type columns:
 - `ADD_TO_SET(value, set)`
 - `REMOVE_FROM_SET(value, set)`
- If you abort `mysql` in the middle of a query, you should open another connection and kill the old running query. Alternatively, an attempt should be made to detect this in the server.
- Add a storage engine interface for table information so that you can use it as a system table. This would be a bit slow if you requested information about all tables, but very flexible. `SHOW INFO FROM tbl_name` for basic table information should be implemented.
- Allow `SELECT a FROM tbl_name1 LEFT JOIN tbl_name2 USING (a);` in this case `a` is assumed to come from `tbl_name1`.
- `DELETE` and `REPLACE` options to the `UPDATE` statement (this deletes rows when a duplicate-key error occurs while updating).

- Change the format of DATETIME to store fractions of seconds.
- Make it possible to use the new GNU `regex` library instead of the current one (the new library should be much faster than the current one).
- Dynamic length rows for MEMORY tables.
- Standards compliance, portability and migration
 - Add `ANY()`, `EVERY()`, and `SOME()` group functions. In standard SQL, these work only on boolean columns, but we can extend these to work on any columns or expressions by treating a value of zero as FALSE and non-zero values as TRUE.
 - Fix the type of `MAX(column)` to be the same as the column type:

```
mysql> CREATE TABLE t1 (a DATE);
mysql> INSERT INTO t1 VALUES (NOW());
mysql> CREATE TABLE t2 SELECT MAX(a) FROM t1;
mysql> SHOW COLUMNS FROM t2;
```

- Speed enhancements
 - Don't allow more than a defined number of threads to run MyISAM recovery at the same time.
 - Change `INSERT INTO ... SELECT` to optionally use concurrent inserts.
 - Add an option to periodically flush key pages for tables with delayed keys if they haven't been used in a while.
 - Allow join on key parts (optimization issue).
 - Add a log file analyzer that can extract information about which tables are hit most often, how often multiple-table joins are executed, and so on. This should help users identify areas of table design that could be optimized to execute much more efficient queries.
- Usability enhancements
 - Return the original column types when doing `SELECT MIN(column) ... GROUP BY`.
 - Make it possible to specify `long_query_time` with a granularity in microseconds.
 - Link the **myisampack** code into the server so that it can perform `PACK` or `COMPRESS` operations.
 - Add a temporary key buffer cache during `INSERT/DELETE/UPDATE` so that we can gracefully recover if the index file gets full.
 - If you perform an `ALTER TABLE` on a table that is symlinked to another disk, create temporary tables on that disk.
 - Implement a `DATE/DATETIME` type that handles time zone information properly, to make dealing with dates in different time zones easier.
 - Fix **configure** so that all libraries (like MyISAM) can be compiled without threads.
 - Allow user variables as `LIMIT` arguments; for example, `LIMIT @a ,@b`.

- Automatic output from **mysql** to a Web browser.
- LOCK DATABASES (with various options).
- Many more variables for SHOW STATUS. Record reads and updates. Selects on a single table and selects with joins. Mean number of tables in selects. Number of ORDER BY and GROUP BY queries.
- **mysqladmin copy database new-database**; this requires a COPY operation to be added to **mysqld**.
- Processlist output should indicate the number of queries/threads.
- SHOW HOSTS for printing information about the hostname cache.
- Change table names from empty strings to NULL for calculated columns.
- Don't use Item_copy_string on numerical values to avoid number-to-string-to-number conversion in case of SELECT COUNT(*)*(id+0) FROM tbl_name GROUP BY id.
- Change so that ALTER TABLE doesn't abort clients that execute INSERT DELAYED.
- Fix so that when columns are referenced in an UPDATE clause, they contain the old values from before the update started.
- New operating systems
 - Port the MySQL clients to LynxOS.

C.4. New Features Planned for the Mid-Term Future

- Implement function: `get_changed_tables(timeout, table1, table2, ...)`.
- Change reading through tables to use `mmap()` when possible. Only compressed tables use `mmap()`.
- Make the automatic timestamp code nicer. Add timestamps to the update log with `SET TIMESTAMP=val;`
- Use read/write mutex in some places to get more speed.
- Automatically close some tables if a table, temporary table, or temporary file gets error 23 (too many open files).
- Better constant propagation. When an occurrence of `col_name=n` is found in an expression, for some constant `n`, replace other occurrences of `col_name` within the expression with `n`. Currently, this is done only for some simple cases.
- Change all const expressions with calculated expressions if possible.
- Optimize `key = expr` comparisons. At the moment, only `key = column` or `key = constant` comparisons are optimized.
- Join some of the copy functions for nicer code.
- Change `sql_yacc.yy` to an inline parser to reduce its size and get better error messages.

- Change the parser to use only one rule per different number of arguments in function.
- Use of full calculation names in the order part (for Access97).
- MINUS, INTERSECT, and FULL OUTER JOIN. (Currently UNION and LEFT|RIGHT OUTER JOIN are supported.)
- Allow SQL_OPTION MAX_SELECT_TIME=val, for placing a time limit on a query.
- Allow updates to be logged to a database.
- Enhance LIMIT to allow retrieval of data from the end of a result set.
- Alarm around client connect/read/write functions.
- Please note the changes to **mysqld_safe**: According to FSSTND (which Debian tries to follow), PID files should go into /var/run/<progrname>.pid and log files into /var/log. It would be nice if you could put the "DATADIR" in the first declaration of "pidfile" and "log" so that the placement of these files can be changed with a single statement.
- Allow a client to request logging.
- Allow the LOAD DATA INFILE statement to read files that have been compressed with **gzip**.
- Fix sorting and grouping of BLOB columns (partly solved).
- Change to use semaphores when counting threads. One should first implement a semaphore library for MIT-pthreads.
- Add full support for JOIN with parentheses.
- As an alternative to the one-thread-per-connection model, manage a pool of threads to handle queries.
- Allow GET_LOCK() to obtain more than one lock. When doing this, it is also necessary to handle the possible deadlocks this change will introduce.

C.5. New Features We Don't Plan to Implement

We aim toward full compliance with ANSI/ISO SQL. There are no features we plan not to implement.

Appendix D. MySQL Change History

This appendix lists the changes from version to version in the MySQL source code.

We are working actively on MySQL 4.1 and 5.0, and provide only critical bugfixes for MySQL 4.0 and MySQL 3.23. We update this section as we add new features, so that everybody can follow the development.

Our TODO section contains what further plans we have for MySQL 4.1 and 5.0. See Appendix C, *MySQL and the Future (the TODO)*.

Note that we tend to update the manual at the same time we make changes to MySQL. If you find a recent version of MySQL listed here that you can't find on our download page (<http://dev.mysql.com/downloads/>), it means that the version has not yet been released.

The date mentioned with a release version is the date of the last BitKeeper ChangeSet on which the release was based, not the date when the packages were made available. The binaries are usually made available a few days after the date of the tagged ChangeSet, because building and testing all packages takes some time.

D.1. Changes in release 5.0.x (Development)

The following changelog shows what has been done in the 5.0 tree:

- Basic support for read-only server side cursors.
- Basic support for (updatable) views. See, for example, Section 21.2, “CREATE VIEW Syntax”.
- Basic support for stored procedures (SQL:2003 style). See Chapter 19, *Stored Procedures and Functions*.
- Initial support for rudimentary triggers.
- Added `SELECT INTO list_of_vars`, which can be of mixed (that is, global and local) types. See Section 19.2.9.3, “SELECT ... INTO Statement”.
- Removed the update log. It is fully replaced by the binary log. If the MySQL server is started with `--log-update`, it is translated to `--log-bin` (or ignored if the server is explicitly started with `--log-bin`), and a warning message is written to the error log. Setting `SQL_LOG_UPDATE` silently sets `SQL_LOG_BIN` instead (or do nothing if the server is explicitly started with `--log-bin`).
- Support for the ISAM storage engine has been removed. If you have ISAM tables, you should convert them before upgrading. See Section 2.10.1, “Upgrading from Version 4.1 to 5.0”.
- Support for RAID options in MyISAM tables has been removed. If you have tables that use these options, you should convert them before upgrading. See Section 2.10.1, “Upgrading from Version 4.1 to 5.0”.
- User variable names are now case insensitive: If you do `SET @a=10;` then `SELECT @A;` now returns 10. Case sensitivity of a variable's value depends on the collation of the value.
- Strict mode, which in essence means that you get an error instead of a warning when inserting an incorrect value into a column. See Section 5.3.2, “The Server SQL Mode”.
- `VARCHAR` and `VARBINARY` columns remember end space. A `VARCHAR()` or `VARBINARY` column can contain up to 65,535 characters or bytes, respectively.
- `MEMORY (HEAP)` tables can have `VARCHAR()` columns.

- When using a constant string or a function that generate a string result in CREATE ... SELECT, MySQL creates the result field based on the max_length of the string/expression:

max_length	Column type
= 0	CHAR(0)
< 512	VARCHAR(max_length)
>= 512	TEXT

For a full list of changes, please refer to the changelog sections for each individual 5.0.x release.

D.1.1. Changes in release 5.0.7 (not released yet)

Functionality added or changed:

- The --delayed-insert option for **mysqldump** has been disabled to avoid causing problems with storage engines that do not support INSERT DELAYED. (Bug #7815 [<http://bugs.mysql.com/7815>])
- Improved the optimizer to be able to use indexes for expressions of the form *indexed_col* NOT IN (*val1*, *val2*, ...) and *indexed_col* NOT BETWEEN *val1* AND *val2*.. (Bug #10561 [<http://bugs.mysql.com/10561>])
- Removed `mysqlshutdown.exe` and `mysqlwatch.exe` from the Windows "No Installer" distribution (they had already been removed from the "With Installer" distribution before). Removed those programs from the source distribution.
- Removed `WinMySQLAdmin` from the source distribution and from the "No Installer" Windows distribution (it had already been removed from the "With Installer" distribution before).

Bugs fixed:

- InnoDB: Do very fast shutdown only if `innodb_fast_shutdown=2`, but wait for threads to exit and release allocated memory if `innodb_fast_shutdown=1`. Starting with MySQL/InnoDB 5.0.5, InnoDB would do brutal shutdown also when `innodb_fast_shutdown=1`. (Bug #9673 [<http://bugs.mysql.com/9673>])
- Fixed a server crash for INSERT or UPDATE when the WHERE clause contained a correlated subquery that referred to a column of the table being modified. (Bug #6384 [<http://bugs.mysql.com/6384>])
- Fixed a problem causing an incorrect result for columns that include an aggregate function as part of an expression when WITH ROLLUP is added to GROUP BY. (Bug #7914 [<http://bugs.mysql.com/7914>])
- Fixed a problem with returning an incorrect result from a view that selected a COALESCE() expression from the result of an outer join. (Bug #9938 [<http://bugs.mysql.com/9938>])
- MySQL was adding a DEFAULT clause to ENUM columns that included no explicit DEFAULT and were defined as NOT NULL. (This is supposed to happen only for columns that are NULL.) (Bug #6237 [<http://bugs.mysql.com/6237>])
- Corrected inappropriate error messages that were displayed when attempting to set the read-only `warning_count` and `error_count` system variables. (Bug #10339 [<http://bugs.mysql.com/10339>])

D.1.2. Changes in release 5.0.6 (not released yet)

Functionality added or changed:

- **Incompatible change:** MyISAM and InnoDB tables created with DECIMAL columns in MySQL 5.0.3 to 5.0.5 will appear corrupt after an upgrade to MySQL 5.0.6. Dump such tables with **mysqldump** before upgrading, and then reload them after upgrading. (The same incompatibility will occur for these tables created in MySQL 5.0.6 after a downgrade to MySQL 5.0.3 to 5.0.5.) (Bug #10465 [<http://bugs.mysql.com/10465>], Bug #10625 [<http://bugs.mysql.com/10625>])
- Added REFERENCED_TABLE_SCHEMA, REFERENCED_TABLE_NAME, and REFERENCED_COLUMN_NAME columns to the KEY_COLUMN_USAGE table of INFORMATION_SCHEMA. (Bug #9587 [<http://bugs.mysql.com/9587>])
- Added a `--show-warnings` option to **mysql** to cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode. In interactive mode, `\w` and `\W` may be used to enable and disable warning display. (Bug #8684 [<http://bugs.mysql.com/8684>])
- Removed a limitation that prevented use of FIFOs as logging targets (such as for the general query log). This modification *does not apply* to the binary log and the relay log. (Bug #8271 [<http://bugs.mysql.com/8271>])
- Added a `--debug` option to **my_print_defaults**.
- When the server cannot read a table because it cannot read the `.frm` file, print a message that the table was created with a different version of MySQL. (This can happen if you create tables that use new features and then downgrade to an older version of MySQL.) (Bug #10435 [<http://bugs.mysql.com/10435>])
- `SHOW VARIABLES` now shows the `slave_compressed_protocol`, `slave_load_tmpdir` and `slave_skip_errors` system variables. (Bug #7800 [<http://bugs.mysql.com/7800>])
- Removed unused system variable `myisam_max_extra_sort_file_size`.
- Changed default value of `myisam_data_pointer_size` from 4 to 6. This allows us to avoid `table is full` errors for most cases.
- The variable `concurrent_insert` now takes 3 values. Setting this to 2 changes MyISAM to do concurrent inserts to end of table if table is in use by another thread.
- New `/*>` prompt for **mysql**. This prompt indicates that a `/* ... */` comment was begun on an earlier line and the closing `*/` sequence has not yet been seen. (Bug #9186 [<http://bugs.mysql.com/9186>])
- If strict SQL mode is enabled, VARCHAR and VARBINARY columns with a length greater than 65,535 no longer are silently converted to TEXT or BLOB columns. Instead, an error occurs. (Bug #8295 [<http://bugs.mysql.com/8295>], Bug #8296 [<http://bugs.mysql.com/8296>])
- The INFORMATION_SCHEMA.SCHEMATA table now has a DEFAULT_COLLATION_NAME column. (Bug #8998 [<http://bugs.mysql.com/8998>])
- InnoDB: When the maximum length of `SHOW INNODB STATUS` output would be exceeded, truncate the beginning of the list of active transactions, instead of truncating the end of the output. (Bug #5436 [<http://bugs.mysql.com/5436>])
- InnoDB: If `innodb_locks_unsafe_for_binlog` option is set and the isolation level of the transaction is not set to serializable then InnoDB uses a consistent read for select in clauses like `INSERT INTO ... SELECT` and `UPDATE ... (SELECT)` that do not specify `FOR UPDATE` or `IN SHARE MODE`. Thus no locks are set to rows read from selected table.

- Updated version of `libedit` to 2.9. (Bug #2596 [<http://bugs.mysql.com/2596>])
- Removed `mysqlshutdown.exe` and `mysqlwatch.exe` from the Windows "With Installer" distribution.

Bugs fixed:

- `MERGE` tables could fail on Windows due to incorrect interpretation of pathname separator characters for filenames in the `.MRG` file. (Bug #10687 [<http://bugs.mysql.com/10687>])
- Fixed a server crash for `INSERT ... ON DUPLICATE KEY UPDATE` with `MERGE` tables, which do not have unique indexes. (Bug #10400 [<http://bugs.mysql.com/10400>])
- Fix `FORMAT()` to do better rounding for double values (for example, `FORMAT(4.55,1)` returns 4.6, not 4.5). (Bug #9060 [<http://bugs.mysql.com/9060>])
- Disallow use of `SESSION` or `GLOBAL` for user variables or local variables in stored routines. (Bug #9286 [<http://bugs.mysql.com/9286>])
- Fixed a server crash when using `GROUP BY ... WITH ROLLUP` on an indexed column in an InnoDB table. (Bug #9798 [<http://bugs.mysql.com/9798>])
- In strict SQL mode, some assignments to numeric columns that should have been rejected were not (such as the result of an arithmetic expression or an explicit `CAST()` operation). (Bug #6961 [<http://bugs.mysql.com/6961>])
- `CREATE TABLE t AS SELECT UUID()` created a `VARCHAR(12)` column, which is too small to hold the 36-character result from `UUID()`. (Bug #9535 [<http://bugs.mysql.com/9535>])
- Fixed a server crash in the `BLACKHOLE` storage engine. (Bug #10175 [<http://bugs.mysql.com/10175>])
- Fixed a server crash resulting from repeated calls to `ABS()` when the argument evaluated to `NULL`. (Bug #10599 [<http://bugs.mysql.com/10599>])
- For a user-defined function invoked from within a prepared statement, the UDF's initialization routine was invoked for each execution of the statement, but the deinitialization routine was not. (It was invoked only when the statement was closed.) Similarly, when invoking a UDF from within a trigger, the initialization routine was invoked but the deinitialization routine was not. For UDFs that have an expensive deinit function (such as `myperl`, this bugfix will have negative performance consequences. (Bug #9913 [<http://bugs.mysql.com/9913>])
- Portability fix for Cygwin: Don't use `#pragma interface` in source files. (Bug #10241 [<http://bugs.mysql.com/10241>])
- Fix `CREATE TABLE ... LIKE` to work when `lower_case_table_names` is set on a case-sensitive filesystem and the source table name is not given in lowercase. (Bug #9761 [<http://bugs.mysql.com/9761>])
- Fixed a server crash resulting from a `CHECK TABLE` statement where the arguments were a view name followed by a table name. (Bug #9897 [<http://bugs.mysql.com/9897>])
- Within a stored procedure, attempting to update a view defined as an inner join failed with a `Table 'tbl_name' was locked with a READ lock and can't be updated` error. (Bug #9481 [<http://bugs.mysql.com/9481>])
- Fixed a problem with `INFORMATION_SCHEMA` tables being inaccessible depending on letter-case used to refer to them. (Bug #10018 [<http://bugs.mysql.com/10018>])
- `my_print_defaults` was ignoring the `--defaults-extra-file` option or crashing when the option was given. (Bug #9136 [<http://bugs.mysql.com/9136>], Bug #9851 [<http://bugs.mysql.com/9851>])

- The `INFORMATION_SCHEMA.COLUMNS` table was missing columns of views for which the user has access. (Bug #9838 [<http://bugs.mysql.com/9838>])
- Fixed a **mysqldump** crash that occurred with the `--complete-insert` option when dumping tables with a large number of long column names. (Bug #10286 [<http://bugs.mysql.com/10286>])
- Corrected a problem where `DEFAULT` values were not assigned properly to `BIT(1)` or `CHAR(1)` columns if certain other columns preceded them in the table definition. (Bug #10179 [<http://bugs.mysql.com/10179>])
- For `MERGE` tables, avoid writing absolute pathnames in the `.MRG` file for the names of the constituent `MyISAM` tables so that if the data directory is moved, `MERGE` tables will not break. For **mysqld**, write just the `MyISAM` table name if it is in the same database as the `MERGE` table, and a path relative to the data directory otherwise. For the embedded servers, absolute pathnames may still be used. (Bug #5964 [<http://bugs.mysql.com/5964>])
- Corrected a problem resolving outer column references in correlated subqueries when using the prepared statements. (Bug #10041 [<http://bugs.mysql.com/10041>])
- Corrected the error message for exceeding the `MAX_CONNECTIONS_PER_HOUR` limit to say `max_connections_per_hour` instead of `max_connections`. (Bug #9947 [<http://bugs.mysql.com/9947>])
- Fixed incorrect memory block allocation for the query cache in the embedded server. (Bug #9549 [<http://bugs.mysql.com/9549>])
- Corrected an inability to select from a view within a stored procedure. (Bug #9758 [<http://bugs.mysql.com/9758>])
- Fixed a server crash resulting from use of `AVG(DISTINCT)` with `GROUP BY ... WITH ROLLUP`. (Bug #9799 [<http://bugs.mysql.com/9799>])
- Fixed a server crash resulting from use of `DISTINCT AVG()` with `GROUP BY ... WITH ROLLUP`. (Bug #9800 [<http://bugs.mysql.com/9800>])
- Fixed a server crash resulting from use of a `CHAR` or `VARCHAR` column with `MIN()` or `MAX()` and `GROUP BY ... WITH ROLLUP`. (Bug #9820 [<http://bugs.mysql.com/9820>])
- Fixed a server crash resulting from use of `SELECT DISTINCT` with a prepared statement that uses a cursor. (Bug #9520 [<http://bugs.mysql.com/9520>])
- Fixed server crash resulting from multiple calls to stored procedure that assigned result of subquery to a variable or compared it to a value with `IN`. (Bug #5963 [<http://bugs.mysql.com/5963>])
- Selecting from a single-table view defined on multiple-table views caused a server crash. (Bug #8528 [<http://bugs.mysql.com/8528>])
- If the file named by a `--defaults-extra-file` option does not exist or is otherwise inaccessible, an error now occurs. (Bug #5056 [<http://bugs.mysql.com/5056>])
- `net_read_timeout` and `net_write_timeout` were not being respected on Windows. (Bug #9721 [<http://bugs.mysql.com/9721>])
- `SELECT` from `INFORMATION_SCHEMA` tables failed if the statement has a `GROUP BY` clause and an aggregate function in the select list. (Bug #9404 [<http://bugs.mysql.com/9404>])
- Corrected some failures of prepared statements for `SQL (PREPARE plus EXECUTE)` to return all rows for some `SELECT` statements. (Bug #9096 [<http://bugs.mysql.com/9096>], Bug #9777 [<http://bugs.mysql.com/9777>])
- Remove extra slashes in `--tmpdir` value (for example, convert `/var//tmp` to `/var/tmp`, because they caused various errors. (Bug #8497 [<http://bugs.mysql.com/8497>])

- Added `Create_routine_priv`, `Alter_routine_priv`, and `Execute_priv` privileges to the `mysql.host` privilege table. (They had been added to `mysql.db` in MySQL 5.0.3 but not to the host table.) (Bug #8166 [<http://bugs.mysql.com/8166>])
- Fixed **configure** to properly recognize whether NTPL is available on Linux. (Bug #2173 [<http://bugs.mysql.com/2173>])
- Incomplete results were returned from `INFORMATION_SCHEMA.COLUMNS` for `INFORMATION_SCHEMA` tables for non-root users. (Bug #10261 [<http://bugs.mysql.com/10261>])
- Fixed a portability problem in compiling `mysql.cc` with **VC++** on Windows. (Bug #10245 [<http://bugs.mysql.com/10245>])
- `SELECT 0/0` returned 0 rather than `NULL`. (Bug #10404 [<http://bugs.mysql.com/10404>])
- `MAX()` for an `INT UNSIGNED` (unsigned 4-byte integer) column could return negative values if the column contained values larger than 2^{31} . (Bug #9298 [<http://bugs.mysql.com/9298>])
- `SHOW CREATE VIEW` got confused and could not find the view if there was a temporary table with the same name as the view. (Bug #8921 [<http://bugs.mysql.com/8921>])
- Fixed a deadlock resulting from use of `FLUSH TABLES WITH READ LOCK` while an `INSERT DELAYED` statement is in progress. (Bug #7823 [<http://bugs.mysql.com/7823>])
- The optimizer was choosing suboptimal execution plans for certain outer joins where the right table of a left join (or left table of a right join) had both `ON` and `WHERE` conditions. (Bug #10162 [<http://bugs.mysql.com/10162>])
- `RENAME TABLE` for an `ARCHIVE` table failed if the `.arn` file was not present. (Bug #9911 [<http://bugs.mysql.com/9911>])
- Invoking a stored function that executed a `SHOW` statement resulted in a server crash. (Bug #8408 [<http://bugs.mysql.com/8408>])
- Fixed problems with static variables and do not link with `libsupc++` to allow building on FreeBSD 5.3. (Bug #9714 [<http://bugs.mysql.com/9714>])
- Fixed some **awk** script portability problems in `cmd-line-utils/libedit/makelist.sh`. (Bug #9954 [<http://bugs.mysql.com/9954>])
- Fixed a problem with mishandling of `NULL` key parts in hash indexes on `VARCHAR` columns, resulting in incorrect query results. (Bug #9489 [<http://bugs.mysql.com/9489>], Bug #10176 [<http://bugs.mysql.com/10176>])

D.1.3. Changes in release 5.0.5 (not released)

Functionality added or changed:

- Added support for the `BIT` data type to the `MEMORY`, `InnoDB`, and `BDB` storage engines.
- `SHOW VARIABLES` no longer displays the deprecated `log_update` system variable. (Bug #9738 [<http://bugs.mysql.com/9738>])
- `--innodb-fast-shutdown` is now also settable on the fly (global variable `innodb_fast_shutdown`). It now accepts values 0, 1 and 2 (except on Netware where 2 is disabled); if set to 2, then when the MySQL server shuts down, `InnoDB` will just flush its logs and then shut down brutally (and quickly) as if it was a MySQL crash; no committed transaction will be lost, but a crash recovery will be done at next startup.

Bugs fixed:

- **Security fix:** If **mysqld** was started with `--user=non_existent_user`, it would run using the privileges of the account it was invoked from, even if that was `root`. (Bug #9833 [<http://bugs.mysql.com/9833>])
- Corrected a failure to resolve a column reference correctly for a `LEFT JOIN` that compared a join column to an `IN` subquery. (Bug #9338 [<http://bugs.mysql.com/9338>])
- Fixed a problem where, after an internal temporary table in memory became too large and had to be converted to an on-disk table, the error indicator was not cleared and the query failed with error 1023 (Can't find record in ''). (Bug #9703 [<http://bugs.mysql.com/9703>])
- Multiple-table updates could produce spurious data-truncation warnings if they used a join across columns that are indexed using a column prefix. (Bug #9103 [<http://bugs.mysql.com/9103>])
- Fixed a string-length comparison problem that caused **mysql** to fail loading dump files containing certain `\'-sequences`. (Bug #9756 [<http://bugs.mysql.com/9756>])
- Fixed a failure to resolve a column reference properly when an outer join involving a view contained a subquery and the column was used in the subquery and the outer query. (Bug #6106 [<http://bugs.mysql.com/6106>], Bug #6107 [<http://bugs.mysql.com/6107>])
- Use of a subquery that used `WITH ROLLUP` in the `FROM` clause of the main query sometimes resulted in a `Column cannot be null` error. (Bug #9681 [<http://bugs.mysql.com/9681>])
- Fixed a memory leak that occurred when selecting from a view that contained a subquery. (Bug #10107 [<http://bugs.mysql.com/10107>])
- Fixed an optimizer bug in computing the union of two ranges for the `OR` operator. (Bug #9348 [<http://bugs.mysql.com/9348>])
- Fixed a segmentation fault in **mysqlcheck** that occurred when the last table checked in `--auto-repair` mode returned an error (such as the table being a `MERGE` table). (Bug #9492 [<http://bugs.mysql.com/9492>])
- `SET @var= CAST(NULL AS [INTEGER|CHAR])` now sets the result type of the variable to `INTEGER/CHAR`. (Bug #6598 [<http://bugs.mysql.com/6598>])
- Incorrect results were returned for queries of the form `SELECT ... LEFT JOIN ... WHERE EXISTS (subquery)`, where the subquery selected rows based on an `IS NULL` condition. (Bug #9516 [<http://bugs.mysql.com/9516>])
- Executing `LOCK TABLES` and then calling a stored procedure caused an error and resulting in the server thinking that no stored procedures exist. (Bug #9566 [<http://bugs.mysql.com/9566>])
- Selecting from a view containing a subquery caused the server to hang. (Bug #8490 [<http://bugs.mysql.com/8490>])
- Within a stored procedure, attempting to execute a multiple-table `UPDATE` failed with a `Table 'tbl_name' was locked with a READ lock and can't be updated` error. (Bug #9486 [<http://bugs.mysql.com/9486>])
- Starting **mysqld** with the `--skip-innodb` and `--default-storage-engine=innodb` (or `--default-table-type=innodb` caused a server crash. (Bug #9815 [<http://bugs.mysql.com/9815>])
- Queries containing `CURRENT_USER()` incorrectly were registered in the query cache. (Bug #9796 [<http://bugs.mysql.com/9796>])
- Setting the `storage_engine` system variable to `MEMORY` succeeded, but retrieving the variable resulted in a value of `HEAP` (the old name for the `MEMORY` storage engine) rather than `MEMORY`. (Bug #10039 [<http://bugs.mysql.com/10039>])
- **mysqlshow** displayed an incorrect row count for tables. (Bug #9391

[<http://bugs.mysql.com/9391>])

- The server died with signal 11 if a non-existent location was specified for the location of the binary log. Now the server exits after printing an appropriate error message. (Bug #9542 [<http://bugs.mysql.com/9542>])
- Fixed a problem in the client/server protocol where the server closed the connection before sending the final error message. The problem could show up as a `Lost connection to MySQL server during query` when attempting to connect to access a non-existent database. (Bug #6387 [<http://bugs.mysql.com/6387>], Bug #9455 [<http://bugs.mysql.com/9455>])
- Fixed a readline-related crash in **mysql** when the user pressed Control-R. (Bug #9568 [<http://bugs.mysql.com/9568>])
- For stored functions that should return a `YEAR` value, corrected a failure of the value to be in `YEAR` format. (Bug #8861 [<http://bugs.mysql.com/8861>])
- Fixed a server crash resulting from invocation of a stored function that returned a value having an `ENUM` or `SET` data type. (Bug #9775 [<http://bugs.mysql.com/9775>])
- Fixed a server crash resulting from invocation of a stored function that returned a value having a `BLOB` data type. (Bug #9102 [<http://bugs.mysql.com/9102>])
- Fixed a server crash resulting from invocation of a stored function that returned a value having a `BIT` data type. (Bug #7648 [<http://bugs.mysql.com/7648>])
- `TIMEDIFF()` with a negative time first argument and positive time second argument produced incorrect results. (Bug #8068 [<http://bugs.mysql.com/8068>])
- Fixed a problem with `OPTIMIZE TABLE` for InnoDB tables being written twice to the binary log. (Bug #9149 [<http://bugs.mysql.com/9149>])
- InnoDB: Prevent `ALTER TABLE` from changing the storage engine if there are foreign key constraints on the table. (Bug #5574 [<http://bugs.mysql.com/5574>], Bug #5670 [<http://bugs.mysql.com/5670>])
- InnoDB: Fixed a bug where next-key locking doesn't allow the insert which does not produce a phantom. (Bug #9354 [<http://bugs.mysql.com/9354>]) If the range is of type `'a' <= unique-column`, InnoDB lock only the `RECORD`, if the record with the column value `'a'` exists in a `CLUSTERED` index. This allows inserts before a range.
- InnoDB: When `FOREIGN_KEY_CHECKS=0`, `ALTER TABLE` and `RENAME TABLE` will ignore any type incompatibilities between referencing and referenced columns. Thus, it will be possible to convert the character sets of columns that participate in a foreign key. Be sure to convert all tables before modifying any data! (Bug #9802 [<http://bugs.mysql.com/9802>])
- Provide more informative error messages in clustered setting when a query is issued against a table that has been modified by another `mysqld` server. (Bug #6762 [<http://bugs.mysql.com/6762>])

D.1.4. Changes in release 5.0.4 (16 Apr 2005)

Functionality added or changed:

- Added `ENGINE=MyISAM` table option when creating `mysql.proc` table in **mysql_create_system_tables** script to make sure the table is created as a `MyISAM` table even if the default storage engine has been changed. (Bug #9496 [<http://bugs.mysql.com/9496>])
- `SHOW CREATE TABLE` for an `INFORMATION_SCHEMA` table no longer prints a `MAX_ROWS` value because the value has no meaning. (Bug #8941 [<http://bugs.mysql.com/8941>])

- Invalid `DEFAULT` values for `CREATE TABLE` now generate errors. (Bug #5902 [<http://bugs.mysql.com/5902>])
- Added `--show-table-type` option to **mysqlshow**, to display a column indicating the table type, as in `SHOW FULL TABLES`. (Bug #5036 [<http://bugs.mysql.com/5036>])
- The way the time zone information is stored into the binary log was changed, so that it's now possible to have a replication master and slave running with different global time zones. A drawback is that replication from 5.0.4 masters to pre-5.0.4 slaves is impossible.
- Added `--with-big-tables` compilation option to **configure**. (Previously it was necessary to pass `-DBIG_TABLES` to the compiler manually in order to enable large table support.) See Section 2.8.2, "Typical **configure** Options" for details.
- New configuration directives `!include` and `!includedir` implemented for including option files and searching directories for option files. See Section 4.3.2, "Using Option Files" for usage.

Bugs fixed:

- The use of `XOR` together with `NOT ISNULL ()` erroneously resulted in some outer joins being converted to inner joins by the optimizer. (Bug #9017 [<http://bugs.mysql.com/9017>])
- Fixed an optimizer problem where extraneous comparisons between `NULL` values in indexed columns were being done for operators such as `=` that are never true for `NULL`. (Bug #8877 [<http://bugs.mysql.com/8877>])
- Fixed the client/server protocol for prepared statements so that reconnection works properly when the connection is killed while `reconnect` is enabled. (Bug #8866 [<http://bugs.mysql.com/8866>])
- A server installed as a Windows service and started with `--shared-memory` could not be stopped. (Bug #9665 [<http://bugs.mysql.com/9665>])
- Fixed a server crash resulting from multiple executions of a prepared statement involving a join of an `INFORMATION_SCHEMA` table with another table. (Bug #9383 [<http://bugs.mysql.com/9383>])
- Fixed `utf8_spanish2_ci` and `ucs2_spanish2_ci` collations to not consider 'r' equal to 'rr'. If you upgrade to this version from an earlier version, you should rebuild the indexes of affected tables. (Bug #9269 [<http://bugs.mysql.com/9269>])
- **mysqldump** dumped core when invoked with `--tmp` and `--single-transaction` options and a non-existent table name. (Bug #9175 [<http://bugs.mysql.com/9175>])
- Allow extra HKSCS and cp950 characters (big5 extension characters) to be accepted in big5 columns. (Bug #9357 [<http://bugs.mysql.com/9357>])
- **mysql.server** no longer uses non-portable **alias** command or LSB functions. (Bug #9852 [<http://bugs.mysql.com/9852>])
- Fixed a server crash resulting from `GROUP BY` on a decimal expression. (Bug #9210 [<http://bugs.mysql.com/9210>])
- In prepared statements, subqueries containing parameters were erroneously treated as `const` tables during preparation, resulting in a server crash. (Bug #8807 [<http://bugs.mysql.com/8807>])
- InnoDB: `ENUM` and `SET` columns were treated incorrectly as character strings. This bug did not manifest itself with `latin1` collations if there were less than about 100 elements in an `ENUM`, but it caused malfunction with `UTF-8`. Old tables will continue to work. In new tables, `ENUM` and `SET` will be internally stored as unsigned integers. (Bug #9526 [<http://bugs.mysql.com/9526>])

- InnoDB: Avoid test suite failures caused by a locking conflict between two server instances at server shutdown/startup. This conflict on advisory locks appears to be the result of a bug in the operating system; these locks should be released when the files are closed, but somehow that does not always happen immediately in Linux. (Bug #9381 [<http://bugs.mysql.com/9381>])
- InnoDB: True VARCHAR: InnoDB stored the 'position' of a row wrong in a column prefix primary key index; this could cause MySQL to complain `ERROR 1032: Can't find record ...` in an update of the primary key, and also some `ORDER BY` or `DISTINCT` queries. (Bug #9314 [<http://bugs.mysql.com/9314>])
- InnoDB: Fix bug in MySQL/InnoDB 5.0.3: SQL statements were not rolled back on error. (Bug #8650 [<http://bugs.mysql.com/8650>])
- Fixed a `Commands out of sync` error when two prepared statements for single-row result sets were open simultaneously. (Bug #8880 [<http://bugs.mysql.com/8880>])
- Fixed a server crash after a call to `mysql_stmt_close()` for single-row result set. (Bug #9159 [<http://bugs.mysql.com/9159>])
- Fixed server crashes for `CREATE TABLE ... SELECT` or `INSERT INTO ... SELECT` when selecting from multiple-table view. (Bug #8703 [<http://bugs.mysql.com/8703>], Bug #9398 [<http://bugs.mysql.com/9398>])
- `TRADITIONAL SQL` mode should prevent inserts where a column with no default value is omitted or set to a value of `DEFAULT`. Fixed cases where this restriction was not enforced. (Bug #5986 [<http://bugs.mysql.com/5986>])
- Fixed a server crash when creating a `PRIMARY KEY` for a table, if the table contained a `BIT` column. (Bug #9571 [<http://bugs.mysql.com/9571>])
- Warning message from `GROUP_CONCAT()` did not always indicate correct number of lines. (Bug #8681 [<http://bugs.mysql.com/8681>])
- The commit count cache for NDB was not properly invalidated when deleting a record using a cursor. (Bug #8585 [<http://bugs.mysql.com/8585>])
- Fixed option-parsing code for the embedded server to understand K, M, and G suffixes for the `net_buffer_length` and `max_allowed_packet` options. (Bug #9472 [<http://bugs.mysql.com/9472>])
- Selecting a `BIT` column failed if the binary client/server protocol was used. (Bug #9608 [<http://bugs.mysql.com/9608>])
- Fixed a permissions problem whereby information in `INFORMATION_SCHEMA` could be exposed to a user with insufficient privileges. (Bug #7214 [<http://bugs.mysql.com/7214>])
- An error now occurs if you try to insert an invalid value via a stored procedure in `STRICT` mode. (Bug #5907 [<http://bugs.mysql.com/5907>])
- Link with `libsupc++` on Fedora Core 3 to get language support functions. (Bug #6554 [<http://bugs.mysql.com/6554>])
- The value of the `CHARACTER_MAXIMUM_LENGTH` and `CHARACTER_OCTET_LENGTH` columns of the `INFORMATION_SCHEMA.COLUMNS` table must be `NULL` for numeric columns, but were not. (Bug #9344 [<http://bugs.mysql.com/9344>])
- `DROP TABLE` did not drop triggers that were defined for the table. `DROP DATABASE` did not drop triggers in the database. (Bug #5859 [<http://bugs.mysql.com/5859>], Bug #6559 [<http://bugs.mysql.com/6559>])
- `CREATE OR REPLACE VIEW` and `ALTER VIEW` now require the `CREATE VIEW` and `DROP` privileges, not `CREATE VIEW` and `DELETE`. (`DELETE` is a row-level privilege, not a table-level privilege.) (Bug #9260 [<http://bugs.mysql.com/9260>])

- Some user variables were not being handled with ``implicit" coercibility. (Bug #9425 [<http://bugs.mysql.com/9425>])
- Setting the `max_error_count` system variable to 0 resulted in a setting of 1. (Bug #9072 [<http://bugs.mysql.com/9072>])
- Fixed a collation coercibility problem that caused a union between binary and non-binary columns to fail. (Bug #6519 [<http://bugs.mysql.com/6519>])
- Fixed a bug in division of floating point numbers. It could cause nine zeroes (000000000) to be inserted in the middle of the quotient. (Bug #9501 [<http://bugs.mysql.com/9501>])
- `INFORMATION_SCHEMA` tables had an implicit upper limit for the number of rows. As a result, not all data could be returned for some queries. (Bug #9317 [<http://bugs.mysql.com/9317>])
- Fixed a problem with the `tee` command in **mysql** that resulted in **mysql** crashing. (Bug #8499 [<http://bugs.mysql.com/8499>])
- `CAST()` now produces warnings when casting incorrect `INTEGER` and `CHAR` values. This also applies to implicit `string` to `number` casts. (Bug #5912 [<http://bugs.mysql.com/5912>])
- `ALTER TABLE` now fails in `STRICT` mode if the alteration generates warnings.
- Using `CONVERT('0000-00-00',date)` or `CAST('0000-00-00' as date)` in `TRADITIONAL SQL` mode now produces a warning. (Bug #6145 [<http://bugs.mysql.com/6145>])
- Inserting a zero date in a `DATE`, `DATETIME` or `TIMESTAMP` column during `TRADITIONAL` mode now produces an error. (Bug #5933 [<http://bugs.mysql.com/5933>])
- Inserting a zero date into a `DATETIME` column in `TRADITIONAL` mode now produces an error.
- `STR_TO_DATE()` now produces errors in strict mode (and warnings otherwise) when given an illegal argument. (Bug #5902 [<http://bugs.mysql.com/5902>])
- Fixed a problem with `ORDER BY` that sometimes caused incorrect sorting of `utf8` data. (Bug #9309 [<http://bugs.mysql.com/9309>])
- Fixed server crash resulting from queries that combined `SELECT DISTINCT`, `SUM()`, and `ROLLUP`. (Bug #8615 [<http://bugs.mysql.com/8615>])
- Incorrect results were returned from queries that combined `SELECT DISTINCT`, `GROUP BY`, and `ROLLUP`. (Bug #8616 [<http://bugs.mysql.com/8616>])
- Too many rows were returned from queries that combined `ROLLUP` and `LIMIT` if `SQL_CALC_FOUND_ROWS` was given. (Bug #8617 [<http://bugs.mysql.com/8617>])
- If on replication master a `LOAD DATA INFILE` is interrupted in the middle (integrity constraint violation, killed connection...), the slave used to skip this `LOAD DATA INFILE` entirely, thus missing some changes if this command permanently inserted/updated some table records before being interrupted. This is now fixed. (Bug #3247 [<http://bugs.mysql.com/3247>])

D.1.5. Changes in release 5.0.3 (23 Mar 2005: Beta)

Note: This Beta release, as any other pre-production release, should not be installed on ``production" level systems or systems with critical data. It is good practice to back up your data before installing any new version of software. Although MySQL has done its best to ensure a high level of quality, protect your data by making a backup as you would for any software beta release.

Functionality added or changed:

- New privilege `CREATE USER` was added.
- Security improvement: The server creates `.frm`, `.MYD`, `.MYI`, `.MRG`, `.ISD`, and `.ISM` table files only if a file with the same name does not already exist. Thanks to Stefano Di Paola <stefano.dipaola@wisec.it> for finding and informing us about this issue. (CAN-2005-0711 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2005-0711>])
- Security improvement: User-defined functions should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`, `xxx_deinit()`, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` functions. **mysqld** by default no longer loads UDFs unless they have at least one auxiliary symbol defined in addition to the main symbol. The `--allow-suspicious-udfs` option controls whether UDFs that have only an `xxx` symbol can be loaded. By default, the option is off. **mysqld** also checks UDF filenames when it reads them from the `mysql.func` table and rejects those that contain directory pathname separator characters. (It already checked names as given in `CREATE FUNCTION` statements.) See Section 27.2.3.1, “UDF Calling Sequences for simple functions”, Section 27.2.3.2, “UDF Calling Sequences for aggregate functions”, and Section 27.2.3.6, “User-defined Function Security Precautions”. Thanks to Stefano Di Paola <stefano.dipaola@wisec.it> for finding and informing us about this issue. (CAN-2005-0709 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2005-0709>], CAN-2005-0710 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2005-0710>])
- Support for the ISAM storage engine has been removed. If you have ISAM tables, you should convert them before upgrading. See Section 2.10.1, “Upgrading from Version 4.1 to 5.0”.
- Support for RAID options in MyISAM tables has been removed. If you have tables that use these options, you should convert them before upgrading. See Section 2.10.1, “Upgrading from Version 4.1 to 5.0”.
- Added support for `AVG(DISTINCT)`.
- `ONLY_FULL_GROUP_BY` no longer is included in the ANSI composite SQL mode. (Bug #8510 [<http://bugs.mysql.com/8510>])
- **mysqld_safe** will create the directory where the UNIX socket file is to be located if the directory does not exist. This applies only to the last component of the directory pathname. (Bug #8513 [<http://bugs.mysql.com/8513>])
- The coercibility for the return value of functions such as `USER()` or `VERSION()` now is “system constant” rather than “implicit.” This makes these functions more coercible than column values so that comparisons of the two do not result in `Illegal mix of collations` errors. `COERCIBILITY()` was modified to accommodate this new coercibility value. See Section 12.8.3, “Information Functions”.
- User variable coercibility has been changed from “coercible” to “implicit.” That is, user variables have the same coercibility as column values.
- Boolean full-text phrase searching now requires only that matches contain exactly the same words as the phrase and in the same order. Non-word characters no longer need match exactly.
- `CHECKSUM TABLE` returns a warning for non-existing tables. The checksum value remains `NULL` as before. (Bug #8256 [<http://bugs.mysql.com/8256>])
- The server now includes a timestamp in the `Ready for connections` message that is written to the error log at startup. (Bug #8444 [<http://bugs.mysql.com/8444>])
- Added `SQL_NOTES` session variable to cause Note-level warnings not to be recorded. (Bug #6662 [<http://bugs.mysql.com/6662>])
- Allowed the service-installation command for Windows servers to specify a single option other than `--defaults-file` following the service name. This is for compatibility with MySQL 4.1. (Bug #7856 [<http://bugs.mysql.com/7856>])

- InnoDB: **Upgrading from 4.1:** The sorting order for end-space in TEXT columns for InnoDB tables has changed. Starting from 5.0.3, InnoDB compares TEXT columns as space-padded at the end. If you have a non-unique index on a TEXT column, you should run CHECK TABLE on it, and run OPTIMIZE TABLE if the check reports errors. If you have a UNIQUE INDEX on a TEXT column, you should rebuild the table with OPTIMIZE TABLE.
- InnoDB: Commit after every 10,000 copied rows when executing ALTER TABLE, CREATE INDEX, DROP INDEX or OPTIMIZE TABLE. This makes it much faster to recover from an aborted operation.
- Added VAR_POP() and STDDEV_POP() as standard SQL aliases for the VARIANCE() and STDDEV() functions that compute population variance and standard deviation. Added new VAR_SAMP() and STDDEV_SAMP() functions to compute sample variance and standard deviation. (Bug #3190 [<http://bugs.mysql.com/3190>])
- Fixed a problem with out-of-order packets being sent (ERROR after OK or EOF) following a KILL QUERY statement. (Bug #6804 [<http://bugs.mysql.com/6804>])
- Retrieving from a view defined as a SELECT that mixed UNION ALL and UNION DISTINCT resulted in a different result than retrieving from the original SELECT. (Bug #6565 [<http://bugs.mysql.com/6565>])
- Fixed a problem with non-optimal index_merge query execution plans being chosen on IRIX. (Bug #8578 [<http://bugs.mysql.com/8578>])
- BIT in column definitions now is a distinct data type; it no longer is treated as a synonym for TINYINT(1).
- Bit-field values can be written using b'value' notation. value is a binary value written using 0s and 1s.
- From the Windows distribution, predefined accounts without passwords for remote users ("root@", "@%") were removed (other distributions never had them).
- Added mysql_library_init() and mysql_library_end() as synonyms for the mysql_server_init() and mysql_server_end() C API functions. mysql_library_init() and mysql_library_end() are #define symbols, but the names more clearly indicate that they should be called when beginning and ending use of a MySQL C API library no matter whether the application uses libmysqlclient or libmysqld. (Bug #6149 [<http://bugs.mysql.com/6149>])
- SHOW COLUMNS now displays NO rather than blank in the Null output column if the corresponding table column cannot be NULL.
- Changed XML format for **mysql** from <col_name>col_value</col_name> to <field name="col_name">col_value</field> to allow for proper encoding of column names that are not legal as element names. (Bug #7811 [<http://bugs.mysql.com/7811>])
- Added --innodb-checksums and --innodb-doublewrite options for **mysqld**.
- Added --large-pages option for **mysqld**.
- Added multi_read_range system variable.
- SHOW DATABASES, SHOW TABLES, SHOW COLUMNS, and so forth display information about the INFORMATION_SCHEMA database. Also, several SHOW statements now accept a WHERE clause specifying which output rows to display. See Chapter 22, *The INFORMATION_SCHEMA Information Database*.
- Added the CREATE ROUTINE and ALTER ROUTINE privileges, and made the EXECUTE privilege operational.
- InnoDB: Corrected a bug in the crash recovery of ROW_FORMAT=COMPACT tables that caused

corruption. (Bug #7973 [<http://bugs.mysql.com/7973>]) There may still be bugs in the crash recovery, especially in COMPACT tables.

- When the MyISAM storage engine detects corruption of a MyISAM table, a message describing the problem now is written to the error log.
- InnoDB: When MySQL/InnoDB is compiled on Mac OS X 10.2 or earlier, detect the operating system version at run time and use the `fcntl()` file flush method on Mac OS X versions 10.3 and later. In Mac OS X, `fsync()` does not flush the write cache in the disk drive, but the special `fcntl()` does; however, the flush request is ignored by some external devices. Failure to flush the buffers may cause severe database corruption at power outages.
- InnoDB: Implemented fast TRUNCATE TABLE. The old approach (deleting rows one by one) may be used if the table is being referenced by foreign keys. (Bug #7150 [<http://bugs.mysql.com/7150>])
- Added `cp932` (SJIS for Windows Japanese) and `ujcsjis` (UJIS for Windows Japanese) character sets.
- Added several InnoDB status variables. See Section 5.3.4, “Server Status Variables”.
- Added the FEDERATED storage engine. See Section 14.6, “The FEDERATED Storage Engine”.
- SHOW CREATE TABLE now uses USING *index_type* rather than TYPE *index_type* to specify an index type. (Bug #7233 [<http://bugs.mysql.com/7233>])
- InnoDB now supports a fast TRUNCATE TABLE. One visible change from this is that auto-increment values for this table are reset on TRUNCATE.
- Added an `error` member to the `MYSQL_BIND` data structure that is used in the C API for prepared statements. This member is used for reporting data truncation errors. Truncation reporting is enabled via the new `MYSQL_REPORT_DATA_TRUNCATION` option for the `mysql_options()` C API function.
- API change: the `reconnect` flag in the `MYSQL` structure is now set to 0 by `mysql_real_connect()`. Only those client programs which didn't explicitly set this flag to 0 or 1 after `mysql_real_connect()` experience a change. Having automatic reconnection enabled by default was considered too dangerous (after reconnection, table locks, temporary tables, user and session variables are lost).
- FLUSH TABLES WITH READ LOCK is now killable while it's waiting for running COMMIT statements to finish.
- MEMORY (HEAP) can have VARCHAR() fields.
- VARCHAR columns now remember end space. A VARCHAR() column can now contain up to 65535 bytes. For more details, see Section D.1, “Changes in release 5.0.x (Development)”. If the table handler doesn't support the new VARCHAR type, then it's converted to a CHAR column. Currently this happens for NDB tables.
- InnoDB: Introduced a compact record format that does not store the number of columns or the lengths of fixed-size columns. The old format can be requested by specifying `ROW_FORMAT=REDUNDANT`. The new format (`ROW_FORMAT=COMPACT`) is the default. The new format typically saves 20 % of disk space and memory.
- InnoDB: Setting the initial `AUTO_INCREMENT` value for an InnoDB table using `CREATE TABLE ... AUTO_INCREMENT = n` now works, and `ALTER TABLE ... AUTO_INCREMENT = n` resets the current value.
- `Seconds_Behind_Master` is NULL (which means “unknown”) if the slave SQL thread is not running, or if the slave I/O thread is not running or not connected to master. It is zero if the SQL thread has caught up to the I/O thread. It no longer grows indefinitely if the master is idle.

- The MySQL server aborts immediately instead of simply issuing a warning if it is started with the `--log-bin` option but cannot initialize the binary log at startup (that is, an error occurs when writing to the binary log file or binary log index file).
- The binary log file and binary log index file now are handled the same way as MyISAM tables when there is a ```disk full``` or ```quota exceeded``` error. See Section A.4.3, “How MySQL Handles a Full Disk”.
- The MySQL server now aborts when started with option `--log-bin-index` and without `--log-bin`, and when started with `--log-slave-updates` and without `--log-bin`.
- If the MySQL server is started without an argument to `--log-bin` and without `--log-bin-index`, thus not providing a name for the binary log index file, a warning is issued because MySQL falls back to using the hostname for that name, and this is prone to replication issues if the server's hostname's gets changed later. See Section 1.7.7.4, “Open Bugs and Design Deficiencies in MySQL”.
- Added account-specific `MAX_USER_CONNECTIONS` limit, which allows you to specify the maximum number of concurrent connections for the account. Also, all limited resources now are counted per account (instead of being counted per user + host pair as it was before). Use the `--old-style-user-limits` option to get the old behavior.
- InnoDB: A shared record lock (`LOCK_REC_NOT_GAP`) is now taken for a matching record in the foreign key check because inserts can be allowed into gaps.
- InnoDB: Relaxed locking in `INSERT...SELECT`, single table `UPDATE...SELECT` and single table `DELETE...SELECT` clauses when `innodb_locks_unsafe_for_binlog` is used and isolation level of the transaction is not serializable. InnoDB uses consistent read in these cases for a selected table.
- Added a new global system variable `slave_transaction_retries`: if the replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or exceeded InnoDB's `innodb_lock_wait_timeout` or NDBCluster's `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The default is 10. (Bug #8325 [<http://bugs.mysql.com/8325>])
- When a client releases a user-level lock, `DO RELEASE_LOCK ()` will not be written to the binary log anymore (this makes the binary log smaller); as a counterpart, the slave does not actually take the lock when it executes `GET_LOCK ()`. This is mainly an optimization and should not affect existing setups. (Bug #7998 [<http://bugs.mysql.com/7998>])
- The way the character set information is stored into the binary log was changed, so that it's now possible to have a replication master and slave running with different global character sets. A drawback is that replication from 5.0.3 masters to pre-5.0.3 slaves is impossible.
- The `LOAD DATA` statement was extended to support user variables in the target column list, and an optional `SET` clause. Now one can perform some transformations on data after they have been read and before they are inserted into the table. For example:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

Also, replication of `LOAD DATA` was changed, so you can't replicate such statements from a 5.0.3 master to pre-5.0.3 slaves.

Bugs fixed:

- If a MyISAM table on Windows had `INDEX DIRECTORY` or `DATA DIRECTORY` table options, **mysqldump** dumped the directory pathnames with single-backslash pathname separators.

This would cause syntax errors when importing the dump file. **mysqldump** now changes `\` to `/` in the pathnames on Windows. (Bug #6660 [<http://bugs.mysql.com/6660>])

- `mysql_fix_privilege_tables` now fixes that the `mysql` privilege tables can be used in MySQL 4.1. This allows one to easily downgrade to 4.1 or run MySQL 5.0 and 4.1 with the same privilege files for testing purposes.
- Fixed bug creating user with GRANT fails with password but works without, (Bug #7905 [<http://bugs.mysql.com/7905>])
- **mysqldump** misinterpreted `'_'` and `'%'` characters in the names of tables to be dumped as wild-card characters. (Bug #9123 [<http://bugs.mysql.com/9123>])
- The definition of the enumeration-valued `sql_mode` column of the `mysql.proc` table was missing some of the current allowable SQL modes, so stored routines would not necessarily execute with the SQL mode in effect at the time of routine definition. (Bug #8902 [<http://bugs.mysql.com/8902>])
- REPAIR TABLE did not invalidate query results in the query cache that were generated from the table. (Bug #8480 [<http://bugs.mysql.com/8480>])
- In strict or traditional SQL mode, too-long string values assigned to string columns (CHAR, VARCHAR, BINARY, VARBINARY, TEXT, or BLOB) were correctly truncated, but the server returned an SQLSTATE value of 01000 (should be 22001). (Bug #6999 [<http://bugs.mysql.com/6999>], Bug #9029 [<http://bugs.mysql.com/9029>])
- Stored functions that used cursors could return incorrect results. (Bug #8386 [<http://bugs.mysql.com/8386>])
- `AES_DECRYPT(col_name, key)` could fail to return NULL for invalid values in `col_name`, if `col_name` was declared as NOT NULL. (Bug #8669 [<http://bugs.mysql.com/8669>])
- Ordering by unsigned expression (more complex than a column reference) was treating the value as signed, producing incorrectly sorted results. (Bug #7425 [<http://bugs.mysql.com/7425>])
- HAVING was treating unsigned columns as signed. (Bug #7425 [<http://bugs.mysql.com/7425>])
- Fixed a problem with boolean full-text searches on `utf8` columns where a double quote in the search string caused a server crash. (Bug #8351 [<http://bugs.mysql.com/8351>])
- For a query with both GROUP BY and COUNT(DISTINCT) clauses and a FROM clause with a subquery, NULL was returned for any VARCHAR column selected by the subquery. (Bug #8218 [<http://bugs.mysql.com/8218>])
- Fixed a bug in TRUNCATE, which did not work within stored procedures. A workaround has been made so that within stored procedures, TRUNCATE is executed like DELETE. This was necessary because TRUNCATE is implicitly locking tables. (Bug #8850 [<http://bugs.mysql.com/8850>])
- Fixed an optimizer bug that caused incorrectly ordered result from a query that used a FULLTEXT index to retrieve rows and there was another index that was usable for ORDER BY. For such a query, EXPLAIN showed `fulltext` join type, but regular (not FULLTEXT) index in the Key column. (Bug #6635 [<http://bugs.mysql.com/6635>])
- If SELECT DISTINCT named an index column multiple times in the select list, the server tried to access different key fields for each instance of the column, which could result in a crash. (Bug #8532 [<http://bugs.mysql.com/8532>])
- For a stored function that refers to a given table, invoking the function while selecting from the same table resulted in a server crash. (Bug #8405 [<http://bugs.mysql.com/8405>])
- Comparison of a DECIMAL column containing NULL to a subquery that produced DECIMAL

values resulted in a server crash. (Bug #8397 [<http://bugs.mysql.com/8397>])

- The `--set-character-set` option for **myisamchk** was changed to `--set-collation`. The value needed for specifying how to sort indexes is a collation name, not a character set name. (Bug #8349 [<http://bugs.mysql.com/8349>])
- Hostname matching didn't work if a netmask was specified for table-specific privileges. (Bug #3309 [<http://bugs.mysql.com/3309>])
- Corruption of MyISAM table indexes could occur with `TRUNCATE TABLE` if the table had already been opened. For example, this was possible if the table had been opened implicitly by selecting from a MERGE table that mapped to the MyISAM table. The server now issues an error message for `TRUNCATE TABLE` under these conditions. (Bug #8306 [<http://bugs.mysql.com/8306>])
- Setting the connection collation to a value different from the server collation followed by a `CREATE TABLE` statement that included a quoted default value resulted in a server crash. (Bug #8235 [<http://bugs.mysql.com/8235>])
- Fixed handling of table-name matching in **mysqlhotcopy** to accommodate `DBD::mysql 2.9003` and up (which implement identifier quoting). (Bug #8136 [<http://bugs.mysql.com/8136>])
- Selecting from a view defined as a join caused a server crash if the query cache was enabled. (Bug #8054 [<http://bugs.mysql.com/8054>])
- Results in the query cache generated from a view were not properly invalidated after `ALTER VIEW` or `DROP VIEW` on that view. (Bug #8050 [<http://bugs.mysql.com/8050>])
- `FOUND_ROWS()` returned an incorrect value after a `SELECT SQL_CALC_FOUND_ROWS DISTINCT` statement that selected constants and included `GROUP BY` and `LIMIT` clauses. (Bug #7945 [<http://bugs.mysql.com/7945>])
- Selecting from an `INFORMATION_SCHEMA` table combined with a subselect on an `INFORMATION_SCHEMA` table caused an error with the message `Table tbl_name is corrupted`. (Bug #8164 [<http://bugs.mysql.com/8164>])
- Fixed a problem with equality propagation optimization for prepared statements and stored procedures that caused a server crash upon re-execution of the prepared statement or stored procedure. (Bug #8115 [<http://bugs.mysql.com/8115>], Bug #8849 [<http://bugs.mysql.com/8849>])
- `LEFT OUTER JOIN` between an empty base table and a view on an empty base table caused a server crash. (Bug #7433 [<http://bugs.mysql.com/7433>])
- Use of `GROUP_CONCAT()` in the select list when selecting from a view caused a server crash. (Bug #7116 [<http://bugs.mysql.com/7116>])
- Use of a view in a correlated subquery that contains `HAVING` but no `GROUP BY` caused a server crash. (Bug #6894 [<http://bugs.mysql.com/6894>])
- Handling by `mysql_list_fields()` of references to stored functions within views was incorrect and could result in a server crash. (Bug #6814 [<http://bugs.mysql.com/6814>])
- **mysqldump** now avoids writing `SET NAMES` to the dump output if the server is older than version 4.1 and would not understand that statement. (Bug #7997 [<http://bugs.mysql.com/7997>])
- Fixed problems when selecting from a view that had an `EXISTS` or `NOT EXISTS` subquery. Selecting columns by name caused a server crash. With `SELECT *`, a crash did not occur, but columns in outer query were not resolved properly. (Bug #6394 [<http://bugs.mysql.com/6394>])
- DDL statements for views were not being written to the binary log (and thus not subject to replication). (Bug #4838 [<http://bugs.mysql.com/4838>])
- The `CHAR()` function was not ignoring `NULL` arguments, contrary to the documentation. (Bug #6317 [<http://bugs.mysql.com/6317>])

- Creating a table using a name containing a character that is illegal in `character_set_client` resulted in the character being stripped from the name and no error. The character now is considered an error. (Bug #8041 [<http://bugs.mysql.com/8041>])
- Fixed a problem with the Cyrillic letters I and SHORT I being treated the same by the `utf8_general_ci` collation. (Bug #8385 [<http://bugs.mysql.com/8385>])
- Some `INFORMATION_SCHEMA` columns that contained catalog identifiers were of type `LONGTEXT`. These were changed to `VARCHAR(N)`, where *N* is the appropriate maximum identifier length. (Bug #7215 [<http://bugs.mysql.com/7215>])
- Some `INFORMATION_SCHEMA` columns that contained timestamp values were of type `VARBINARY`. These were changed to `TIMESTAMP`. (Bug #7217 [<http://bugs.mysql.com/7217>])
- An expression that tested a case-insensitive character column against string constants that differed in lettercase could fail because the constants were treated as having a binary collation. (For example, `WHERE city='London' AND city='london'` could fail.) (Bug #7098 [<http://bugs.mysql.com/7098>], Bug #8690 [<http://bugs.mysql.com/8690>])
- The output of the `STATUS (\s)` command in **mysql** had the values for the server and client character sets reversed. (Bug #7571 [<http://bugs.mysql.com/7571>])
- If the slave was running with `--replicate-*-table` options which excluded one temporary table and included another, and the two tables were used in a single `DROP TEMPORARY TABLE IF EXISTS` statement, as the ones the master automatically writes to its binary log upon client's disconnection when client has not explicitly dropped these, the slave could forget to delete the included replicated temporary table. Only the slave needs to be upgraded. (Bug #8055 [<http://bugs.mysql.com/8055>])
- When setting integer system variables to a negative value with `SET VARIABLES`, the value was treated as a positive value modulo 2^{32} . (Bug #6958 [<http://bugs.mysql.com/6958>])
- Corrected a problem with references to `DUAL` where statements such as `SELECT 1 AS a FROM DUAL` would succeed but statements such as `SELECT 1 AS a FROM DUAL LIMIT 1` would fail. (Bug #8023 [<http://bugs.mysql.com/8023>])
- Fixed a server crash caused by `DELETE FROM tbl_name ... WHERE ... ORDER BY tbl_name.col_name` when the `ORDER BY` column was qualified with the table name. (Bug #8392 [<http://bugs.mysql.com/8392>])
- Fixed a bug in `MATCH ... AGAINST` in natural language mode that could cause a server crash if the `FULLTEXT` index was not used in a join (`EXPLAIN` did not show `fulltext join mode`) and the search query matched no rows in the table (Bug #8522 [<http://bugs.mysql.com/8522>]).
- InnoDB: Honor the `--tmpdir` startup option when creating temporary files. Previously, InnoDB temporary files were always created in the temporary directory of the operating system. On Netware, InnoDB will continue to ignore `--tmpdir`. (Bug #5822 [<http://bugs.mysql.com/5822>])
- Platform and architecture information in version information produced for `--version` option on Windows was always `Win95/Win98 (i32)`. More accurately determine platform as `Win32` or `Win64` for 32-bit or 64-bit Windows, and architecture as `ia32` for x86, `ia64` for Itanium, and `axp` for Alpha. (Bug #4445 [<http://bugs.mysql.com/4445>])
- If multiple semicolon-separated statements were received in a single packet, they were written to the binary log as a single event rather than as separate per-statement events. For a server serving as a replication master, this caused replication to fail when the event was sent to slave servers. (Bug #8436 [<http://bugs.mysql.com/8436>])
- Fixed `LOAD INDEX` statement to actually load index in memory. (Bug #8452 [<http://bugs.mysql.com/8452>])

- Fixed a failure of multiple-table updates to replicate properly on slave servers when `--replicate-*-table` options had been specified. (Bug #7011 [<http://bugs.mysql.com/7011>])
- Fixed failure of `CREATE TABLE ... LIKE` Windows when the source or destination table was located in a symlinked database directory. (Bug #6607 [<http://bugs.mysql.com/6607>])
- With `lower_case_table_names` set to 1, **mysqldump** on Windows could write the same table name in different lettercase for different SQL statements. Fixed so that consistent lettercase is used. (Bug #5185 [<http://bugs.mysql.com/5185>])
- **mysqld_safe** now understands the `--help` option. Previously, it ignored the option and attempted to start the server anyway. (Bug #7931 [<http://bugs.mysql.com/7931>])
- Fixed problem in `NO_BACKSLASH_ESCAPES` SQL mode for strings that contained both the string quoting character and backslash. (Bug #6368 [<http://bugs.mysql.com/6368>])
- Fixed some portability issues with overflow in floating point values.
- Prepared statements now gives warnings on prepare.
- Fixed bug in prepared statements with `SUM(DISTINCT ...)`.
- Fixed bug in prepared statements with `OUTER JOIN`.
- Fixed a bug in `CONV()` function returning unsigned `BIGINT` number (third argument is positive, and return value does not fit in 32 bits). (Bug #7751 [<http://bugs.mysql.com/7751>])
- Fixed a failure of the `IN()` operator to return correct result if all values in the list were constants and some of them were using substring functions, for example, `LEFT()`, `RIGHT()`, or `MID()`. (Bug #7716 [<http://bugs.mysql.com/7716>])
- Fixed a crash in `CONVERT_TZ()` function when its second or third argument was from a `const` table (see Section 7.2.1, “EXPLAIN Syntax (Get Information About a SELECT)”). (Bug #7705 [<http://bugs.mysql.com/7705>])
- Fixed a problem with calculation of number of columns in row comparison against subquery. (Bug #8020 [<http://bugs.mysql.com/8020>])
- Fixed erroneous output resulting from `SELECT DISTINCT` combined with a subquery and `GROUP BY`. (Bug #7946 [<http://bugs.mysql.com/7946>])
- Fixed server crash in comparing a nested row expression (for example `row(1, (2, 3))`) with a subquery. (Bug #8022 [<http://bugs.mysql.com/8022>])
- Fixed server crash resulting from certain correlated subqueries with forward references (references to an alias defined later in the outer query). (Bug #8025 [<http://bugs.mysql.com/8025>])
- Fixed server crash resulting from re-execution of prepared statements containing subqueries. (Bug #8125 [<http://bugs.mysql.com/8125>])
- Fixed a bug where `ALTER TABLE` improperly would accept an index on a `TIMESTAMP` column that `CREATE TABLE` would reject. (Bug #7884 [<http://bugs.mysql.com/7884>])
- `SHOW CREATE TABLE` now reports `ENGINE=MEMORY` rather than `ENGINE=HEAP` for a `MEMORY` table (unless the `MYSQL323 SQL` mode is enabled). (Bug #6659 [<http://bugs.mysql.com/6659>])
- Fixed a bug where the use of `GROUP_CONCAT()` with `HAVING` caused a server crash. (Bug #7769 [<http://bugs.mysql.com/7769>])
- Fixed a bug where comparing the result of a subquery to a non-existent column caused a server crash on Windows. (Bug #7885 [<http://bugs.mysql.com/7885>])

- Fixed a bug in a combination of `-not` and `trunc*` operators of full-text search. Using more than one truncated negative search term, was causing empty result set.
- InnoDB: Corrected the handling of trailing spaces in the `ucs2` character set. (Bug #7350 [<http://bugs.mysql.com/7350>], Bug #8771 [<http://bugs.mysql.com/8771>])
- InnoDB: Use native `tmpfile()` function on Netware. All InnoDB temporary files are created under `sys:\tmp`. Previously, InnoDB temporary files were never deleted on Netware.
- Fixed a bug in `max_heap_table_size` handling, that resulted in `Table is full` error when the table was still smaller than the limit. (Bug #7791 [<http://bugs.mysql.com/7791>]).
- Fixed a symlink vulnerability in the `mysqlaccess` script. Reported by Javier Fernandez-Sanguino Pena and Debian Security Audit Team [<http://www.debian.org/security/audit>]. (CAN-2005-0004 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2005-0004>])
- Fixed a bug that caused server crash if some error occurred during filling of temporary table created for derived table or view handling. (Bug #7413 [<http://bugs.mysql.com/7413>])
- Fixed a bug which caused server crash if query containing `CONVERT_TZ()` function with constant arguments was prepared. (Bug #6849 [<http://bugs.mysql.com/6849>])
- Prevent adding `CREATE TABLE ... SELECT` query to the binary log when the insertion of new records partially failed. (Bug #6682 [<http://bugs.mysql.com/6682>])
- Fixed a bug which caused a crash when only the slave I/O thread was stopped and started. (Bug #6148 [<http://bugs.mysql.com/6148>])
- Giving `mysqld` a `SIGHUP` caused it to crash.
- Changed semantics of `CREATE/ALTER/DROP DATABASE` statements so that replication of `CREATE DATABASE` is possible when using `--binlog-do-db` and `--binlog-ignore-db`. (Bug #6391 [<http://bugs.mysql.com/6391>])
- A sequence of `BEGIN` (or `SET AUTOCOMMIT=0`), `FLUSH TABLES WITH READ LOCK`, transactional update, `COMMIT`, `FLUSH TABLES WITH READ LOCK` could hang the connection forever and possibly the MySQL server itself. This happened for example when running the `innobackup` script several times. (Bug #6732 [<http://bugs.mysql.com/6732>])
- `mysqlbinlog` did not print `SET PSEUDO_THREAD_ID` statements in front of `LOAD DATA INFILE` statements inserting into temporary tables, thus causing potential problems when rolling forward these statements after restoring a backup. (Bug #6671 [<http://bugs.mysql.com/6671>])
- InnoDB: Fixed a bug no error message for `ALTER` with InnoDB and `AUTO_INCREMENT` (Bug #7061 [<http://bugs.mysql.com/7061>]). InnoDB now supports `ALTER TABLE ... AUTO_INCREMENT = x` query to set auto increment value for a table.
- Made the MySQL server accept executing `SHOW CREATE DATABASE` even if the connection has an open transaction or locked tables; refusing it made `mysqldump --single-transaction` sometimes fail to print a complete `CREATE DATABASE` statement for some dumped databases. (Bug #7358 [<http://bugs.mysql.com/7358>])
- Fixed that, when encountering a ``disk full'` or ``quota exceeded'` write error, MyISAM sometimes didn't sleep and retry the write, thus resulting in a corrupted table. (Bug #7714 [<http://bugs.mysql.com/7714>])
- Fixed that `--expire-log-days` was not honored if using only transactions. (Bug #7236 [<http://bugs.mysql.com/7236>])
- Fixed that a slave could crash after replicating many `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `REPAIR TABLE` statements from the master. (Bug #6461 [<http://bugs.mysql.com/6461>], Bug #7658 [<http://bugs.mysql.com/7658>])

- **mysqlbinlog** forgot to add backquotes around the collation of user variables (causing later parsing problems as BINARY is a reserved word). (Bug #7793 [<http://bugs.mysql.com/7793>])
- Ensured that **mysqldump --single-transaction** sets its transaction isolation level to REPEATABLE READ before proceeding (otherwise if the MySQL server was configured to run with a default isolation level lower than REPEATABLE READ it could give an inconsistent dump). (Bug #7850 [<http://bugs.mysql.com/7850>])
- Fixed that when using the RPAD() function (or any function adding spaces to the right) in a query that had to be resolved by using a temporary table, all resulting strings had rightmost spaces removed (i.e. RPAD() did not work) (Bug #4048 [<http://bugs.mysql.com/4048>])
- Fixed that a 5.0.3 slave can connect to a master < 3.23.50 without hanging (the reason for the hang is a bug in these quite old masters -- SELECT @@unknown_var hangs them -- which was fixed in MySQL 3.23.50). (Bug #7965 [<http://bugs.mysql.com/7965>])
- InnoDB: Fixed a deadlock without any locking, simple select and update (Bug #7975 [<http://bugs.mysql.com/7975>]). InnoDB now takes an exclusive lock when INSERT ON DUPLICATE KEY UPDATE is checking duplicate keys.
- Fixed a bug where MySQL was allowing concurrent updates (inserts, deletes) to a table if binary logging is enabled. Changed to ensure that all updates are executed in a serialized fashion, because they are executed serialized when binlog is replayed. (Bug #7879 [<http://bugs.mysql.com/7879>])
- Fixed a rare race condition which could lead to FLUSH TABLES WITH READ LOCK hanging. (Bug #8682 [<http://bugs.mysql.com/8682>])
- Fixed a bug that caused the slave to stop on statements that produced an error on the master. (Bug #8412 [<http://bugs.mysql.com/8412>])

D.1.6. Changes in release 5.0.2 (01 Dec 2004)

Functionality added or changed:

- **Warning: Incompatible change!** The precedence of NOT operator has changed so that expressions such as NOT a BETWEEN b AND c are parsed correctly as NOT (a BETWEEN b AND c) rather than as (NOT a) BETWEEN b AND c. The pre-5.0 higher-precedence behavior can be obtained by enabling the new HIGH_NOT_PRECEDENCE SQL mode.
- SHOW STATUS now shows the thread specific status variables and SHOW GLOBAL STATUS shows the status variables for the whole server.
- Added support for the INFORMATION_SCHEMA ``information database" that provides database metadata. See Chapter 22, *The INFORMATION_SCHEMA Information Database*.
- A HAVING clause in a SELECT statement now can refer to columns in the GROUP BY clause, as required by standard SQL.
- Added the CREATE USER and RENAME USER statements.
- Modify DROP USER so that it drops the account, including all its privileges. Formerly, it removed the account record only for an account that had had all privileges revoked.
- Added IS [NOT] *boolean_value* syntax, where *boolean_value* is TRUE, FALSE, or UNKNOWN.
- Added several InnoDB status variables. See Section 5.3.4, "Server Status Variables".
- Implemented the WITH CHECK OPTION clause for CREATE VIEW.

- `CHECK TABLE` now works for views.
- The `SCHEMA` and `SCHEMAS` keywords are now accepted as synonyms for `DATABASE` and `DATABASES`.
- Added initial support for rudimentary triggers (the `CREATE TRIGGER` and `DROP TRIGGER` statements).
- Added basic support for read-only server side cursors.
- `mysqldump --single-transaction --master-data` is now able to take an online (non-blocking) dump of InnoDB and report the corresponding binary log coordinates, which makes a backup suitable for point-in-time recovery, roll-forward or replication slave creation. See Section 8.8, “The `mysqldump` Database Backup Program”.
- Added `--start-datetime`, `--stop-datetime`, `--start-position`, `--stop-position` options to `mysqlbinlog` (makes point-in-time recovery easier).
- Made the MySQL server not react to signals `SIGHUP` and `SIGQUIT` on Mac OS X 10.3. This is needed because under this OS, the MySQL server receives lots of these signals (reported as Bug #2030 [<http://bugs.mysql.com/2030>]).
- New `--auto-increment-increment` and `--auto-increment-offset` startup options. These allow you to set up a server to generate auto-increment values that don't conflict with another server.
- MySQL now by default checks dates and in strict mode allows only fully correct dates. If you want MySQL to behave as before, you should enable the new `ALLOW_INVALID_DATES` SQL mode.
- Added `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, and `TRADITIONAL` SQL modes. The `TRADITIONAL` mode is shorthand for all the preceding modes. When using mode `TRADITIONAL`, MySQL generates an error if you try to insert a wrong value in a column. It does not adjust the value to the closest possible legal value.
- MySQL now remembers which columns were declared to have default values. In `STRICT_TRANS_TABLES/STRICT_ALL_TABLES` mode, you now get an error if you do an `INSERT` without specifying all columns that don't have a default value. A side effect of this is that when you do `SHOW CREATE` for a new table, you no longer see a `DEFAULT` value for a column for which you didn't specify a default value.
- The compilation flag `DONT_USE_DEFAULT_FIELDS` was removed because you can get the same behavior by setting the `sql_mode` system variable to `STRICT_TRANS_TABLES`.
- Added `NO_AUTO_CREATE_USER` SQL mode to prevent `GRANT` from automatically creating new users if it would otherwise do so, unless a password also is specified.
- We now detect too-large floating point numbers during statement parsing and generate an error messages for them.
- Renamed the `sql_updatable_view_key` system variable to `updatable_views_with_limit`. This variable now can have only two values:
 - 1 or YES: Don't issue an error message (warning only) if a `VIEW` without presence of a key in the underlying table is used in queries with a `LIMIT` clause for updating. (This is the default value.)
 - 0 or NO: Prohibit update of a `VIEW`, which does not contain a key in the underlying table and the query uses a `LIMIT` clause (usually get from GUI tools).
- Reverted output format of `SHOW TABLES` to old pre-5.0.1 format that did not include a table type column. To get the additional column that lists the table type, use `SHOW FULL TABLES`

now.

- The **mysql_fix_privilege_tables** script now initializes the global `CREATE VIEW` and `SHOW VIEW` privileges in the `user` table to the value of the `CREATE` privilege in that table.
- If the server finds that the `user` table has not been upgraded to include the view-related privilege columns, it treats each account as having view privileges that are the same as its `CREATE` privilege.
- InnoDB: If you specify the option `innodb_locks_unsafe_for_binlog` in `my.cnf`, InnoDB in an `UPDATE` or a `DELETE` only locks the rows that it updates or deletes. This greatly reduces the probability of deadlocks.
- A connection doing a rollback now displays "Rolling back" in the `State` column of `SHOW PROCESSLIST`.
- **mysqlbinlog** now prints an informative commented line (thread id, timestamp, server id, etc) before each `LOAD DATA INFILE`, like it does for other queries; unless `--short-form` is used.

Bugs fixed:

- Fixed that **mysqlbinlog --read-from-remote-server** sometimes couldn't accept two binary log files on the command line. (Bug #4507 [<http://bugs.mysql.com/4507>])
- Fixed that **mysqlbinlog --position --read-from-remote-server** had incorrect # at lines. (Bug #4506 [<http://bugs.mysql.com/4506>])
- Fixed that `CREATE TABLE ... TYPE=HEAP ... AS SELECT...` caused replication slave to stop. (Bug #4971 [<http://bugs.mysql.com/4971>])
- Fixed that `mysql_options(...,MYSQL_OPT_LOCAL_INFILE,...)` failed to disable `LOAD DATA LOCAL INFILE`. (Bug #5038 [<http://bugs.mysql.com/5038>])
- Fixed that `disable-local-infile` option had no effect if client read it from a configuration file using `mysql_options(...,MYSQL_READ_DEFAULT,...)`. (Bug #5073 [<http://bugs.mysql.com/5073>])
- Fixed that `SET GLOBAL SYNC_BINLOG` did not work on some platforms (Mac OS X). (Bug #5064 [<http://bugs.mysql.com/5064>])
- Fixed that **mysql-test-run** failed on the `rpl_trunc_binlog` test if running test from the installed (the target of 'make install') directory. (Bug #5050)
- Fixed that **mysql-test-run** failed on the `grant_cache` test when run as Unix user 'root'. (Bug #4678 [<http://bugs.mysql.com/4678>])
- Fixed an unlikely deadlock which could happen when using `KILL`. (Bug #4810)
- Fixed a crash when one connection got KILLED while it was doing `START SLAVE`. (Bug #4827 [<http://bugs.mysql.com/4827>])
- Made `FLUSH TABLES WITH READ LOCK` block `COMMIT` if server is running with binary logging; this ensures that the binary log position can be trusted when doing a full backup of tables and the binary log. (Bug #4953 [<http://bugs.mysql.com/4953>])
- Fixed that the counter of an `auto_increment` column was not reset by `TRUNCATE TABLE` if the table was a temporary one. (Bug #5033 [<http://bugs.mysql.com/5033>])
- Fixed slave `SQL` thread so that the `SET COLLATION_SERVER...` statements it replicates don't advance its position (so that if it gets interrupted before the actual update query, it later redoes the `SET`). (Bug #5705 [<http://bugs.mysql.com/5705>])

- Fixed that if the slave SQL thread found a syntax error in a query (which should be rare, as the master parsed it successfully), it stops. (Bug #5711 [<http://bugs.mysql.com/5711>])
- Fixed that if a write to a MyISAM table fails because of a full disk or an exceeded disk quota, it prints a message to the error log every 10 minutes, and waits until disk becomes free. (Bug #3248 [<http://bugs.mysql.com/3248>])
- Fixed problem introduced in 4.0.21 where a connection starting a transaction, doing updates, then `FLUSH TABLES WITH READ LOCK`, then `COMMIT`, would cause replication slaves to stop (complaining about error 1223). Bug surfaced when using the InnoDB `innobackup` script. (Bug #5949 [<http://bugs.mysql.com/5949>])
- `OPTIMIZE TABLE`, `REPAIR TABLE`, and `ANALYZE TABLE` are now replicated without any error code in the binary log. (Bug #5551 [<http://bugs.mysql.com/5551>])
- If a connection had an open transaction but had done no updates to transactional tables (for example if had just done a `SELECT FOR UPDATE` then executed a non-transactional update, that update automatically committed the transaction (thus releasing InnoDB's row-level locks etc). (Bug #5714 [<http://bugs.mysql.com/5714>])
- If a connection was interrupted by a network error and did a rollback, the network error code got stored into the `BEGIN` and `ROLLBACK` binary log events; that caused superfluous slave stops. (Bug #6522 [<http://bugs.mysql.com/6522>])
- Fixed a bug which prevented `mysqlbinlog` from being able to read from `stdin`, for example, when piping the output from `zcat` to `mysqlbinlog`. (Bug #7853 [<http://bugs.mysql.com/7853>])

D.1.7. Changes in release 5.0.1 (27 Jul 2004)

Note: This build passes our test suite and fixes a lot of reported bugs found in the previous 5.0.0 release. However, please be aware that this is not a "standard MySQL build" in the sense that there are still some open critical bugs in our bugs database at <http://bugs.mysql.com/> that affect this release as well. We are actively fixing these and will make a new release where these are fixed as soon as possible. However, this binary should be a good candidate for testing new MySQL 5.0 features for future products.

Functionality added or changed:

- **Warning: Incompatible change!** C API change: `mysql_shutdown()` now requires a second argument. This is a source-level incompatibility that affects how you compile client programs; it does not affect the ability of compiled clients to communicate with older servers. See Section 24.2.3.54, "`mysql_shutdown()`".
- When installing a MySQL server as a Windows service, the installation command can include a `--local-service` option following the service name to cause the server to run using the `LocalService` Windows account that has limited privileges. This is in addition to the `--defaults-file` option that also can be given following the service name.
- Added support for read-only and updatable views based on a single table or other updatable views. View use requires that you upgrade your grant tables to add the view-related privileges. See Section 2.10.7, "Upgrading the Grant Tables".
- Implemented a new "greedy search" optimizer that can significantly reduce the time spent on query optimization for some many-table joins. (You are affected if not only some particular `SELECT` is slow, but even using `EXPLAIN` for it takes a noticeable amount of time.) Two new system variables, `optimizer_search_depth` and `optimizer_prune_level`, can be used to fine-tune optimizer behavior.
- A stored procedure is no longer "global." That is, it now belongs to a specific database:
 - When a database is dropped, all routines belonging to that database are also dropped.

- Procedure names may be qualified, for example, `db.p()`
- When executed from another database, an implicit `USE db_name` is in effect.
- Explicit `USE db_name` statements no longer are allowed in a stored procedure.

See Chapter 19, *Stored Procedures and Functions*.

- Fixed `SHOW TABLES` output field name and values according to standard. Field name changed from `Type` to `table_type`, values are `BASE TABLE`, `VIEW` and `ERROR`. (Bug #4603 [<http://bugs.mysql.com/4603>])
- Added the `sql_updatable_view_key` system variable.
- Added the `--replicate-same-server-id` server option.
- Added `Last_query_cost` status variable that reports optimizer cost for last compiled query.
- Added the `--to-last-log` option to **mysqlbinlog**, for use in conjunction with `--read-from-remote-server`.
- Added the `--innodb-safe-binlog` server option, which adds consistency guarantees between the content of InnoDB tables and the binary log. See Section 5.10.4, “The Binary Log”.
- `OPTIMIZE TABLE` for InnoDB tables is now mapped to `ALTER TABLE` instead of `ANALYZE TABLE`. This rebuilds the table, which updates index statistics and frees space in the clustered index.
- `sync_frm` is now a settable global variable (not only a startup option).
- For replication of `MEMORY (HEAP)` tables: Made the master automatically write a `DELETE FROM` statement to its binary log when a `MEMORY` table is opened for the first time since master's startup. This is for the case where the slave has replicated a non-empty `MEMORY` table, then the master is shut down and restarted: the table is now empty on master; the `DELETE FROM` empties it on slave too. Note that even with this fix, between the master's restart and the first use of the table on master, the slave still has out-of-date data in the table. But if you use the `--init-file` option to populate the `MEMORY` table on the master at startup, it ensures that the failing time interval is zero. (Bug #2477 [<http://bugs.mysql.com/2477>])
- When a session having open temporary tables terminates, the statement automatically written to the binary log is now `DROP TEMPORARY TABLE IF EXISTS` instead of `DROP TEMPORARY TABLE`, for more robustness.
- The MySQL server now returns an error if `SET SQL_LOG_BIN` is issued by a user without the `SUPER` privilege (in previous versions it just silently ignored the statement in this case).
- Changed that when the MySQL server has binary logging disabled (that is, no `--log-bin` option was used), then no transaction binary log cache is allocated for connections. This should save `binlog_cache_size` bytes of memory (32KB by default) for every connection.
- Added the `sync_binlog=N` global variable and startup option, which makes the MySQL server synchronize its binary log to disk (`fdatasync()`) after every Nth write to the binary log.
- Changed the slave `SQL` thread to print less useless error messages (no more message duplication; no more messages when an error is skipped because of `slave-skip-errors`).
- `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, single-table `DELETE`, and single-table `UPDATE` now are written to the binary log even if they changed nothing on the master (for example, even if a `DELETE` matched no rows). The old behavior sometimes caused bad surprises in replication setups.

- Replication and **mysqlbinlog** now have better support for the case that the session character set and collation variables are changed within a given session. See Section 6.7, “Replication Features and Known Problems”.
- Killing a `CHECK TABLE` statement does not result in the table being marked as “corrupted” any more; the table remains as if `CHECK TABLE` had not even started. See Section 13.5.5.3, “`KILL` Syntax”.

Bugs fixed:

- Strange results with index `(x, y) ... WHERE x=val_1 AND y>=val_2 ORDER BY pk`; (Bug #3155 [<http://bugs.mysql.com/3155>])
- Subquery and order by (Bug #3118 [<http://bugs.mysql.com/3118>])
- `ALTER DATABASE` caused the client to hang if the database did not exist. (Bug #2333 [<http://bugs.mysql.com/2333>])
- `SLAVE START` (which is a deprecated syntax, `START SLAVE` should be used instead) could crash the slave. (Bug #2516 [<http://bugs.mysql.com/2516>])
- Multiple-table `DELETE` statements were never replicated by the slave if there were any `--replicate-*-table` options. (Bug #2527 [<http://bugs.mysql.com/2527>])
- The MySQL server did not report any error if a statement (submitted through `mysql_real_query()` or `mysql_stmt_prepare()`) was terminated by garbage characters. This can happen if you pass a wrong `length` parameter to these functions. The result was that the garbage characters were written into the binary log. (Bug #2703 [<http://bugs.mysql.com/2703>])
- Replication: If a client connects to a slave server and issues an administrative statement for a table (for example, `OPTIMIZE TABLE` or `REPAIR TABLE`), this could sometimes stop the slave SQL thread. This does not lead to any corruption, but you must use `START SLAVE` to get replication going again. (Bug #1858 [<http://bugs.mysql.com/1858>])
- Made clearer the error message that one gets when an update is refused because of the `--read-only` option. (Bug #2757 [<http://bugs.mysql.com/2757>])
- Fixed that `--replicate-wild-*-table` rules apply to `ALTER DATABASE` when the table pattern is `%`, as is the case for `CREATE DATABASE` and `DROP DATABASE`. (Bug #3000 [<http://bugs.mysql.com/3000>])
- Fixed that when a Rotate event is found by the slave SQL thread in the middle of a transaction, the value of `Relay_Log_Pos` in `SHOW SLAVE STATUS` remains correct. (Bug #3017 [<http://bugs.mysql.com/3017>])
- Corrected the master's binary log position that InnoDB reports when it is doing a crash recovery on a slave server. (Bug #3015 [<http://bugs.mysql.com/3015>])
- Changed the column `Seconds_Behind_Master` in `SHOW SLAVE STATUS` to never show a value of #1. (Bug #2826 [<http://bugs.mysql.com/2826>])
- Changed that when a `DROP TEMPORARY TABLE` statement is automatically written to the binary log when a session ends, the statement is recorded with an error code of value zero (this ensures that killing a `SELECT` on the master does not result in a superfluous error on the slave). (Bug #3063 [<http://bugs.mysql.com/3063>])
- Changed that when a thread handling `INSERT DELAYED` (also known as a `delayed_insert` thread) is killed, its statements are recorded with an error code of value zero (killing such a thread does not endanger replication, so we thus avoid a superfluous error on the slave). (Bug #3081 [<http://bugs.mysql.com/3081>])

- Fixed deadlock when two `START SLAVE` commands were run at the same time. (Bug #2921 [<http://bugs.mysql.com/2921>])
- Fixed that a statement never triggers a superfluous error on the slave, if it must be excluded given the `--replicate-*` options. The bug was that if the statement had been killed on the master, the slave would stop. (Bug #2983 [<http://bugs.mysql.com/2983>])
- The `--local-load` option of **mysqlbinlog** now requires an argument.
- Fixed a segmentation fault when running `LOAD DATA FROM MASTER` after `RESET SLAVE`. (Bug #2922 [<http://bugs.mysql.com/2922>])
- **mysqlbinlog --read-from-remote-server** read all binary logs following the one that was requested. It now stops at the end of the requested file, the same as it does when reading a local binary log. There is an option `--to-last-log` to get the old behavior. (Bug #3204 [<http://bugs.mysql.com/3204>])
- Fixed **mysqlbinlog --read-from-remote-server** to print the exact positions of events in the "at #" lines. (Bug #3214 [<http://bugs.mysql.com/3214>])
- Fixed a rare error condition that caused the slave SQL thread spuriously to print the message `Binlog has bad magic number and stop` when it was not necessary to do so. (Bug #3401 [<http://bugs.mysql.com/3401>])
- Fixed **mysqlbinlog** not to forget to print a `USE` statement under rare circumstances where the binary log contained a `LOAD DATA INFILE` statement. (Bug #3415 [<http://bugs.mysql.com/3415>])
- Fixed a memory corruption when replicating a `LOAD DATA INFILE` when the master had version 3.23. (Bug #3422 [<http://bugs.mysql.com/3422>])
- Multiple-table `DELETE` statements were always replicated by the slave if there were some `--replicate-*-ignore-table` options and no `--replicate-*-do-table` options. (Bug #3461 [<http://bugs.mysql.com/3461>])
- Fixed a crash of the MySQL slave server when it was built with `--with-debug` and replicating itself. (Bug #3568 [<http://bugs.mysql.com/3568>])
- Fixed that in some replication error messages, a very long query caused the rest of the message to be invisible (truncated), by putting the query last in the message. (Bug #3357 [<http://bugs.mysql.com/3357>])
- If `server-id` was not set using startup options but with `SET GLOBAL`, the replication slave still complained that it was not set. (Bug #3829 [<http://bugs.mysql.com/3829>])
- **mysql_fix_privilege_tables** didn't correctly handle the argument of its `--password=#` option. (Bug #4240 [<http://bugs.mysql.com/4240>])
- Fixed potential memory overrun in `mysql_real_connect()` (which required a compromised DNS server and certain operating systems). (Bug #4017 [<http://bugs.mysql.com/4017>], CAN-2004-0836 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0836>])
- During the installation process of the server RPM on Linux, **mysqld** was run as the `root` system user, and if you had `--log-bin=<somewhere_out_of_var_lib_mysql>` it created binary log files owned by `root` in this directory, which remained owned by `root` after the installation. This is now fixed by starting **mysqld** as the `mysql` system user instead. (Bug #4038 [<http://bugs.mysql.com/4038>])
- Made `DROP DATABASE` honor the value of `lower_case_table_names`. (Bug #4066 [<http://bugs.mysql.com/4066>])
- The slave SQL thread refused to replicate `INSERT ... SELECT` if it examined more than 4 billion rows. (Bug #3871 [<http://bugs.mysql.com/3871>])

- **mysqlbinlog** didn't escape the string content of user variables, and did not deal well when these variables were in non-ASCII character sets; this is now fixed by always printing the string content of user variables in hexadecimal. The character set and collation of the string is now also printed. (Bug #3875 [<http://bugs.mysql.com/3875>])
- Fixed incorrect destruction of expression that led to a server crash on complex AND/OR expressions if query was ignored (either by a replication server because of `--replicate-*-table` rules, or by any MySQL server because of a syntax error). (Bug #3969 [<http://bugs.mysql.com/3969>], Bug #4494 [<http://bugs.mysql.com/4494>])
- If `CREATE TEMPORARY TABLE t SELECT` failed while loading the data, the temporary table was not dropped. (Bug #4551 [<http://bugs.mysql.com/4551>])
- Fixed that when a multiple-table `DROP TABLE` failed to drop a table on the master server, the error code was not written to the binary log. (Bug #4553 [<http://bugs.mysql.com/4553>])
- When the slave SQL thread was replicating a `LOAD DATA INFILE` statement, it didn't show the statement in the output of `SHOW PROCESSLIST`. (Bug #4326 [<http://bugs.mysql.com/4326>])

D.1.8. Changes in release 5.0.0 (22 Dec 2003: Alpha)

Functionality added or changed:

- **Important note:** If you upgrade to MySQL 4.1.1 or higher, it is difficult to downgrade back to 4.0 or 4.1.0! That is because, for earlier versions, InnoDB is not aware of multiple tablespaces.
- Added support for `SUM(DISTINCT)`, `MIN(DISTINCT)`, and `MAX(DISTINCT)`.
- The `KILL` statement now takes `CONNECTION` and `QUERY` modifiers. The first is the same as `KILL` with no modifier (it kills a given connection thread). The second kills only the statement currently being executed by the connection.
- Added `TIMESTAMPADD()` and `TIMESTAMPDIFF()` functions.
- Added `WEEK` and `QUARTER` values as `INTERVAL` arguments for the `DATE_ADD()` and `DATE_SUB()` functions.
- New binary log format that enables replication of these session variables: `sql_mode`, `SQL_AUTO_IS_NULL`, `FOREIGN_KEY_CHECKS` (which was replicated since 4.0.14, but here it's done more efficiently and takes less space in the binary logs), `UNIQUE_CHECKS`. Other variables (like character sets, `SQL_SELECT_LIMIT`, ...) will be replicated in upcoming 5.0.x releases.
- Implemented Index Merge optimization for OR clauses. See Section 7.2.6, "Index Merge Optimization".
- Basic support for stored procedures (SQL:2003 style). See Chapter 19, *Stored Procedures and Functions*.
- Added `SELECT INTO list_of_vars`, which can be of mixed (that is, global and local) types. See Section 19.2.9.3, "SELECT ... INTO Statement".
- Easier replication upgrade (5.0.0 masters can read older binary logs and 5.0.0 slaves can read older relay logs). See Section 6.5, "Replication Compatibility Between MySQL Versions" for more details). The format of the binary log and relay log is changed compared to that of MySQL 4.1 and older.

Bugs fixed:

D.2. Changes in release 4.1.x (Production)

Version 4.1 of the MySQL server includes many enhancements and new features. Binaries for this version are available for download at <http://dev.mysql.com/downloads/mysql-4.1.html>.

- Subqueries and derived tables (unnamed views). See Section 13.1.8, “Subquery Syntax”.
- `INSERT . . . ON DUPLICATE KEY UPDATE . . .` syntax. This allows you to `UPDATE` an existing row if the insert would cause a duplicate value in a `PRIMARY` or `UNIQUE` key. (`REPLACE` allows you to overwrite an existing row, which is something entirely different.) See Section 13.1.4, “INSERT Syntax”.
- A newly designed `GROUP_CONCAT()` aggregate function. See Section 12.9, “Functions and Modifiers for Use with `GROUP BY` Clauses”.
- Extensive Unicode (UTF8) support.
- Table names and column names now are stored in UTF8. This makes MySQL more flexible, but might cause some problems upgrading if you have table or column names that use characters outside of the standard 7-bit US-ASCII range. See Section 2.10.2, “Upgrading from Version 4.0 to 4.1”.
- Character sets can be defined per column, table, and database.
- New key cache for `MYISAM` tables with many tunable parameters. You can have multiple key caches, preload index into caches for batches...
- `BTREE` index on `HEAP` tables.
- Support for OpenGIS spatial types (geographical data). See Chapter 18, *Spatial Extensions in MySQL*.
- `SHOW WARNINGS` shows warnings for the last command. See Section 13.5.4.20, “SHOW WARNINGS Syntax”.
- Faster binary protocol with prepared statements and parameter binding. See Section 24.2.4, “C API Prepared Statements”.
- You can now issue multiple statements with a single C API call and then read the results in one go. See Section 24.2.9, “C API Handling of Multiple Query Execution”.
- Create Table: `CREATE [TEMPORARY] TABLE [IF NOT EXISTS] table2 LIKE table1`.
- Server based `HELP` command that can be used in the **mysql** command-line client (and other clients) to get help for SQL statements.

For a full list of changes, please refer to the changelog sections for each individual 4.1.x release.

D.2.1. Changes in release 4.1.13 (not released yet)

Functionality added or changed:

Bugs fixed:

- InnoDB: In `DROP DATABASE`, check for all referencing tables from other databases before dropping any tables. (Bug #10335 [<http://bugs.mysql.com/10335>])
- Fixed an overly strict debugging assertion that caused debug server builds to fail for some `col_name = const_expr`, where `const_expr` was a constant expression such as a sub-

query. (Bug #10020 [<http://bugs.mysql.com/10020>])

- SUBSTR() did not work properly for input in the ucs2 character set. (Bug #10344 [<http://bugs.mysql.com/10344>])
- Fixed a problem causing an incorrect result for columns that include an aggregate function as part of an expression when WITH ROLLUP is added to GROUP BY. (Bug #7914 [<http://bugs.mysql.com/7914>])
- Fixed a server crash for INSERT ... ON DUPLICATE KEY UPDATE with MERGE tables, which do not have unique indexes. (Bug #10400 [<http://bugs.mysql.com/10400>])
- CREATE TABLE t AS SELECT UUID() created a VARCHAR(12) column, which is too small to hold the 36-character result from UUID(). (Bug #9535 [<http://bugs.mysql.com/9535>])
- Portability fix for Cygwin: Don't use #pragma interface or #pragma implementation in source files. (Bug #10241 [<http://bugs.mysql.com/10241>])
- Fixed a **mysqldump** crash that occurred with the --complete-insert option when dumping tables with a large number of long column names. (Bug #10286 [<http://bugs.mysql.com/10286>])
- ALTER TABLE ... ENABLE INDEXES treated NULL values as equal when collecting index statistics for MyISAM tables, resulting in different statistics than generated by ANALYZE TABLE and causing the optimizer to make poor index choices later. The same problem occurred for bulk insert statistics collection. Now NULL values are treated as unequal, just as for ANALYZE TABLE. (Bug #9622 [<http://bugs.mysql.com/9622>])

D.2.2. Changes in release 4.1.12 (13 May 2005)

Note: The fix for interpretation of MERGE table .MRG files (Bug #10687 [<http://bugs.mysql.com/10687>]) was made for Windows builds after MySQL 4.1.12 was released and is present in MySQL 4.1.12a.

Functionality added or changed:

- Added --debug option to **my_print_defaults**.
- When the server cannot read a table because it cannot read the .frm file, print a message that the table was created with a different version of MySQL. (This can happen if you create tables that use new features and then downgrade to an older version of MySQL.) (Bug #10435 [<http://bugs.mysql.com/10435>])
- New /*> prompt for **mysql**. This prompt indicates that a /* ... */ comment was begun on an earlier line and the closing */ sequence has not yet been seen. (Bug #9186 [<http://bugs.mysql.com/9186>])
- Added cp1250_croatian_ci collation. (Bug #6505 [<http://bugs.mysql.com/6505>])
- Updated version of libedit to 2.9. (Bug #2596 [<http://bugs.mysql.com/2596>])
- InnoDB: When the maximum length of SHOW INNODB STATUS output would be exceeded, truncate the beginning of the list of active transactions, instead of truncating the end of the output. (Bug #5436 [<http://bugs.mysql.com/5436>])
- InnoDB: When FOREIGN_KEY_CHECKS=0, ALTER TABLE and RENAME TABLE will ignore any type incompatibilities between referencing and referenced columns. Thus, it will be possible to convert the character sets of columns that participate in a foreign key. Be sure to convert all tables before modifying any data! (Bug #9802 [<http://bugs.mysql.com/9802>])
- InnoDB: Setting the initial AUTO_INCREMENT value for an InnoDB table using CREATE

TABLE ... AUTO_INCREMENT = *n* now works, and ALTER TABLE ... AUTO_INCREMENT = *n* resets the current value. (Bug #7061 [<http://bugs.mysql.com/7061>])

- InnoDB: If `innodb_locks_unsafe_for_binlog` option set and isolation level of the transaction is not set to serializable then InnoDB uses a consistent read for select in clauses like `INSERT INTO...SELECT` and `UPDATE...(SELECT)` that do not specify `FOR UPDATE` or `IN SHARE MODE`. Thus no locks are set to rows read from selected table.
- Previously in MySQL 4.1, an illegal mix of collations error occurred when mixing strings from same character set when one had a non-binary collation and the other a binary collation. Now the binary collation takes precedence, so that both strings are treated as having the binary collation. This restores compatibility with MySQL 4.0 behavior.
- Added the cp932 Japanese character set.

Bugs fixed:

- **Security fix:** If `mysqld` was started with `--user=non_existent_user`, it would run using the privileges of the account it was invoked from, even if that was `root`. (Bug #9833 [<http://bugs.mysql.com/9833>])
- MERGE tables could fail on Windows due to incorrect interpretation of pathname separator characters for filenames in the .MRG file. (Bug #10687 [<http://bugs.mysql.com/10687>])
- CHAR and VARCHAR columns that used the sjis character set were not being saved correctly, causing the following columns to be corrupted. (Bug #10493 [<http://bugs.mysql.com/10493>])
- For a user-defined function invoked from within a prepared statement, the UDF's initialization routine was invoked for each execution of the statement, but the deinitialization routine was not. (It was invoked only when the statement was closed.) For UDFs that have an expensive deinit function (such as `myperl`), this bugfix will have negative performance consequences. (Bug #9913 [<http://bugs.mysql.com/9913>])
- Fix `CREATE TABLE ... LIKE` to work when `lower_case_table_names` is set on a case-sensitive filesystem and the source table name is not given in lowercase. (Bug #9761 [<http://bugs.mysql.com/9761>])
- `my_print_defaults` was ignoring the `--defaults-extra-file` option or crashing when the option was given. (Bug #9136 [<http://bugs.mysql.com/9136>], Bug #9851 [<http://bugs.mysql.com/9851>])
- For MERGE tables, avoid writing absolute pathnames in the .MRG file for the names of the constituent MyISAM tables so that if the data directory is moved, MERGE tables will not break. For `mysqld`, write just the MyISAM table name if it is in the same database as the MERGE table, and a path relative to the data directory otherwise. For the embedded servers, absolute pathnames may still be used. (Bug #5964 [<http://bugs.mysql.com/5964>])
- Corrected the error message for exceeding the `MAX_CONNECTIONS_PER_HOUR` limit to say `max_connections_per_hour` instead of `max_connections`. (Bug #9947 [<http://bugs.mysql.com/9947>])
- Fixed incorrect memory block allocation for the query cache in the embedded server. (Bug #9549 [<http://bugs.mysql.com/9549>])
- Fixed a **configure** problem in checking for capability of performing atomic operations. (Bug #7970 [<http://bugs.mysql.com/7970>])
- `net_read_timeout` and `net_write_timeout` were not being respected on Windows. (Bug #9721 [<http://bugs.mysql.com/9721>])
- An error occurred if you specified a default value of `TRUE` or `FALSE` for a `BOOL` column. (Bug #9666 [<http://bugs.mysql.com/9666>])

- Corrected some failures of prepared statements for SQL (`PREPARE` plus `EXECUTE`) to return all rows for some `SELECT` statements. (Bug #9096 [<http://bugs.mysql.com/9096>], Bug #9777 [<http://bugs.mysql.com/9777>])
- Remove extra slashes in `--tmpdir` value (for example, convert `/var//tmp` to `/var/tmp`, because they caused various errors. (Bug #8497 [<http://bugs.mysql.com/8497>])
- Fixed a sort order problem with the `latin2_croatian_ci` collation. All tables that have indexes that use this collation will be treated as crashed. After upgrading, for each such table, you must use `CHECK TABLE` and possibly repair the table. (Bug #6505 [<http://bugs.mysql.com/6505>])
- **mysqld** was not checking whether the PID file was successfully created. (Bug #5843 [<http://bugs.mysql.com/5843>])
- With `DISTINCT CONCAT(col, ...)` returned incorrect results when the arguments to `CONCAT()` were columns with an integer data type declared with a display width narrower than the values in the column. (For example, if an `INT(1)` column contain 1111.) (Bug #4082 [<http://bugs.mysql.com/4082>])
- Fixed **configure** to properly recognize whether NTPL is available on Linux. (Bug #2173 [<http://bugs.mysql.com/2173>])
- Fixed a portability problem in compiling `mysql.cc` with **VC++** on Windows. (Bug #10245 [<http://bugs.mysql.com/10245>])
- `CAST(string_argument AS UNSIGNED)` didn't work for big integers above the signed range. Now this function and `CAST(string_argument AS SIGNED)` also produces warnings for wrong string arguments. (Bug #7036 [<http://bugs.mysql.com/7036>])
- Fixed compile problem with MinGW. Thanks to Nils Durner for patch! (Bug #8872 [<http://bugs.mysql.com/8872>])
- MySQL no longer automatically blocks IP numbers for which `gethostbyname_r()` fails when the reason is that the DNS server is down. Thanks to Jeremy Cole for patch. (Bug #8467 [<http://bugs.mysql.com/8467>])
- Fixed a bug in the key cache that caused a core dump. (Bug #10167 [<http://bugs.mysql.com/10167>])
- The `--delimiter` option for the **nds_select** program was non-functional. (Bug #10287 [<http://bugs.mysql.com/10287>])
- `MAX()` for an `INT UNSIGNED` (unsigned 4-byte integer) column could return negative values if the column contained values larger than 2^{31} . (Bug #9298 [<http://bugs.mysql.com/9298>])
- Fixed a deadlock resulting from use of `FLUSH TABLES WITH READ LOCK` while an `INSERT DELAYED` statement is in progress. (Bug #7823 [<http://bugs.mysql.com/7823>])
- Multiple-table updates could produce spurious data-truncation warnings if they used a join across columns that are indexed using a column prefix. (Bug #9103 [<http://bugs.mysql.com/9103>])
- Use of a subquery that used `WITH ROLLUP` in the `FROM` clause of the main query sometimes resulted in a `Column cannot be null` error. (Bug #9681 [<http://bugs.mysql.com/9681>])
- `RENAME TABLE` for an `ARCHIVE` table failed if the `.arn` file was not present. (Bug #9911 [<http://bugs.mysql.com/9911>])
- Fixed an optimizer problem where extraneous comparisons between `NULL` values in indexed columns were being done for operators such as `=` that are never true for `NULL`. (Bug #8877 [<http://bugs.mysql.com/8877>])
- `SELECT ROUND(expr)` produced a different result than `CREATE TABLE ... SELECT`

`ROUND(expr)`. (Bug #9837 [<http://bugs.mysql.com/9837>])

- Fixed some **awk** script portability problems in **cmd-line-utils/libedit/makelist.sh**. (Bug #9954 [<http://bugs.mysql.com/9954>])
- Changed metadata for result of `SHOW KEYS`: Data type for `Sub_part` column now is `SMALLINT` rather than `TINYINT` because key part length can be longer than 255. (Bug #9439 [<http://bugs.mysql.com/9439>])
- Fixed some problems with **myisampack** on 64-bit systems that resulted in segmentation violations. (Bug #9487 [<http://bugs.mysql.com/9487>])
- Fixed an optimizer bug in computing the union of two ranges for the `OR` operator. (Bug #9348 [<http://bugs.mysql.com/9348>])
- Fixed an index corruption problem for `MyISAM` tables that resulted from the 4.1 behavior of padding values with blanks for comparison: Dumping a table with **mysqldump**, reloading it, and then re-running the binary log against it crashed the index and necessitated a repair. (Bug #9188 [<http://bugs.mysql.com/9188>])
- Fixed a segmentation fault in **mysqlcheck** that occurred when the last table checked in `--auto-repair` mode returned an error (such as the table being a `MERGE` table). (Bug #9492 [<http://bugs.mysql.com/9492>])
- Fixed the client/server protocol for prepared statements so that reconnection works properly when the connection is killed while `reconnect` is enabled. (Bug #8866 [<http://bugs.mysql.com/8866>])
- `INSERT ... ON DUPLICATE KEY UPDATE` incorrectly updated a `TIMESTAMP` column to the current timestamp, even if the update list included `col_name = col_name` for that column to prevent the update. (Bug #7806 [<http://bugs.mysql.com/7806>])
- Starting **mysqld** with the `--skip-innodb` and `--default-storage-engine=innodb` (or `--default-table-type=innodb` caused a server crash. (Bug #9815 [<http://bugs.mysql.com/9815>])
- Queries containing `CURRENT_USER()` incorrectly were registered in the query cache. (Bug #9796 [<http://bugs.mysql.com/9796>])
- A server installed as a Windows service and started with `--shared-memory` could not be stopped. (Bug #9665 [<http://bugs.mysql.com/9665>])
- **mysqldump** dumped core when invoked with `--tmp` and `--single-transaction` options and a non-existent table name. (Bug #9175 [<http://bugs.mysql.com/9175>])
- Additional fix for `mysql_server_init()` and `mysql_server_end()` C API functions so that stopping and restarting the embedded server will not cause a crash. (Bug #7344 [<http://bugs.mysql.com/7344>])
- **mysql.server** no longer uses non-portable **alias** command or `LSB` functions. (Bug #9852 [<http://bugs.mysql.com/9852>])
- Fixed a `readline`-related crash in **mysql** when the user pressed Control-R. (Bug #9568 [<http://bugs.mysql.com/9568>])
- `TIMEDIFF()` with a negative time first argument and positive time second argument produced incorrect results. (Bug #8068 [<http://bugs.mysql.com/8068>])
- Fixed a bug that caused concurrent inserts to be allowed into the tables in the `SELECT ... UNION ...` part of `INSERT ... SELECT ... UNION ...`. This could result in the incorrect order of queries in the binary log. (Bug #9922 [<http://bugs.mysql.com/9922>])
- The warning message from `GROUP_CONCAT()` did not always indicate the correct number of lines. (Bug #8681 [<http://bugs.mysql.com/8681>])

- InnoDB: ENUM and SET columns were treated incorrectly as character strings. This bug did not manifest itself with latin1 collations, but it caused malfunction with utf8. Old tables will continue to work. In new tables, ENUM and SET will be internally stored as unsigned integers. (Bug #9526 [<http://bugs.mysql.com/9526>])
- InnoDB: Avoid test suite failures caused by a locking conflict between two server instances at server shutdown/startup. This conflict on advisory locks appears to be the result of a bug in the operating system; these locks should be released when the files are closed, but somehow that does not always happen immediately in Linux. (Bug #9381 [<http://bugs.mysql.com/9381>])
- InnoDB: Prevent ALTER TABLE from changing the storage engine if there are foreign key constraints on the table. (Bug #5574 [<http://bugs.mysql.com/5574>], Bug #5670 [<http://bugs.mysql.com/5670>])
- InnoDB: Fixed a deadlock without any locking, simple select and update. (Bug #7975 [<http://bugs.mysql.com/7975>]) InnoDB now takes an exclusive lock when INSERT ON DUPLICATE KEY UPDATE is checking duplicate keys.
- Fix for auto-increment not working with INSERT .. SELECT and NDB storage engine. (Bug #9675 [<http://bugs.mysql.com/9675>])

D.2.3. Changes in release 4.1.11 (01 Apr 2005)

Functionality added or changed:

- ONLY_FULL_GROUP_BY no longer is included in the ANSI composite SQL mode. (Bug #8510 [<http://bugs.mysql.com/8510>])
- **mysqld_safe** will create the directory where the UNIX socket file is to be located if the directory does not exist. This applies only to the last component of the directory pathname. (Bug #8513 [<http://bugs.mysql.com/8513>])
- The coercibility for the return value of functions such as USER() or VERSION() now is "system constant" rather than "implicit." This makes these functions more coercible than column values so that comparisons of the two do not result in illegal mix of collations errors. COERCIBILITY() was modified to accommodate this new coercibility value. See Section 12.8.3, "Information Functions".
- User variable coercibility has been changed from "coercible" to "implicit." That is, user variables have the same coercibility as column values.
- NULL now is considered more coercible than string constants. This resolves some illegal mix of collations conflicts.
- Modified the parser to allow SELECT statements following the UNION keyword to be subqueries in parentheses. (Bug #2435 [<http://bugs.mysql.com/2435>])
- For slave replication servers started with --replicate-* options, statements that should not be replicated according those options no longer are written to the slave's general query log. (Bug #8297 [<http://bugs.mysql.com/8297>])
- Added SQL_NOTES session variable to cause Note-level warnings not to be recorded. (Bug #6662 [<http://bugs.mysql.com/6662>])
- InnoDB: Commit after every 10,000 copied rows when executing CREATE INDEX, DROP INDEX or OPTIMIZE TABLE, which are internally implemented as ALTER TABLE. This makes it much faster to recover from an aborted operation.
- Added a new global system variable slave_transaction_retries: If the replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or exceeded InnoDB's innodb_lock_wait_timeout or NDBCluster's TransactionDeadlockDe-

`transactionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The default in MySQL 4.1 is 0. You must explicitly set the value greater than 0 to enable the ``retry" behavior. (In MySQL 5.0.3 or newer, the default is 10.) (Bug #8325 [<http://bugs.mysql.com/8325>])

- Added `--with-big-tables` compilation option to **configure**. (Previously it was necessary to pass `-DBIG_TABLES` to the compiler manually in order to enable large table support.) See Section 2.8.2, “Typical **configure** Options” for details.
- Added configuration directives `!include` and `!includedir` for including option files and searching directories for option files. See Section 4.3.2, “Using Option Files” for usage.

Bugs fixed:

- Disallow use of `SESSION` or `GLOBAL` for user variables. (Bug #9286 [<http://bugs.mysql.com/9286>])
- The use of `XOR` together with `NOT ISNULL()` erroneously resulted in some outer joins being converted to inner joins by the optimizer. (Bug #9017 [<http://bugs.mysql.com/9017>])
- Fixed `utf8_spanish2_ci` and `ucs2_spanish2_ci` collations to not consider 'r' equal to 'rr'. If you upgrade to this version from an earlier version, you should rebuild the indexes of affected tables. (Bug #9269 [<http://bugs.mysql.com/9269>])
- Allow extra HKSCS and cp950 characters (`big5` extension characters) to be accepted in `big5` columns. (Bug #9357 [<http://bugs.mysql.com/9357>])
- `BLOB(M)` and `TEXT(M)` columns, with `M` less than 256, were being created as `BLOB` and `TEXT` columns rather than `TINYBLOB` or `TINYTEXT` columns. (Bug #9303 [<http://bugs.mysql.com/9303>])
- Fixed a problem with `INSERT ... SELECT ... ON DUPLICATE KEY UPDATE` where a column named in the insert list and in the `ON DUPLICATE KEY UPDATE` clause was erroneously declared to be ambiguous. (Bug #8147 [<http://bugs.mysql.com/8147>])
- In prepared statements, subqueries containing parameters were erroneously treated as `const` tables during preparation, resulting in a server crash. (Bug #8807 [<http://bugs.mysql.com/8807>])
- Fixed a problem with `OPTIMIZE TABLE` for InnoDB tables being written twice to the binary log. (Bug #9149 [<http://bugs.mysql.com/9149>])
- Provide more informative error messages in clustered setting when a query is issued against a table that has been modified by another `mysqld` server. (Bug #6762 [<http://bugs.mysql.com/6762>])
- For MyISAM tables, `REPAIR TABLE` no longer discard rows that have incorrect checksum. (Bug #9824 [<http://bugs.mysql.com/9824>])
- Depending on index statistics, `GROUP BY col1, col2, ...` could return incorrect results if the first table processed for a join had several indexes that cover the grouped columns. (Bug #9213 [<http://bugs.mysql.com/9213>])
- Fixed incorrect evaluation of `ALL/ANY` subqueries that contain a `HAVING` clause. (Bug #9350 [<http://bugs.mysql.com/9350>])
- Fixed server crash when left expression of `IN/ALL/ANY` comparison was a subquery. (Bug #8888 [<http://bugs.mysql.com/8888>])
- Fixed option-parsing code for the embedded server to understand K, M, and G suffixes for the `net_buffer_length` and `max_allowed_packet` options. (Bug #9472 [<http://bugs.mysql.com/9472>])

- Fixed a crash when using `TIMESTAMP` columns with no minute or second parts in `GROUP BY` with the new system variable set to 1. (Bug #9401 [<http://bugs.mysql.com/9401>])
- If a `MyISAM` table on Windows had `INDEX DIRECTORY` or `DATA DIRECTORY` table options, **mysqldump** dumped the directory pathnames with single-backslash pathname separators. This would cause syntax errors when importing the dump file. **mysqldump** now changes `\` to `'/'` in the pathnames on Windows. (Bug #6660 [<http://bugs.mysql.com/6660>])
- Fixed a server crash caused by use of `NOW()` in a subquery. (Bug #8824 [<http://bugs.mysql.com/8824>])
- Fixed problems with static variables to allow building on Fedora Core 3. (Bug #6554 [<http://bugs.mysql.com/6554>])
- Some user variables were not being handled with ```implicit``` coercibility. (Bug #9425 [<http://bugs.mysql.com/9425>])
- Setting the `max_error_count` system variable to 0 resulted in a setting of 1. (Bug #9072 [<http://bugs.mysql.com/9072>])
- Fixed a collation coercibility problem that caused a union between binary and non-binary columns to fail. (Bug #6519 [<http://bugs.mysql.com/6519>])
- Fixed a problem with the `tee` command in **mysql** that resulted in **mysql** crashing. (Bug #8499 [<http://bugs.mysql.com/8499>])
- On Windows, create shared memory objects with the proper access rights to make them usable when the client and server are running under different accounts. (Bug #8226 [<http://bugs.mysql.com/8226>])
- Bundled `zlib` in the source distribution was upgraded to 1.2.2. (Bug #9118 [<http://bugs.mysql.com/9118>])
- Fixed server crash resulting from queries that combined `SELECT DISTINCT`, `SUM()`, and `ROLLUP`. (Bug #8615 [<http://bugs.mysql.com/8615>])
- Incorrect results were returned from queries that combined `SELECT DISTINCT`, `GROUP BY`, and `ROLLUP`. (Bug #8616 [<http://bugs.mysql.com/8616>])
- Fixed a bug that under certain circumstances could allow a privilege escalation via database wildcards in `GRANT`. (CAN-2004-0957 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0957>])
- Too many rows were returned from queries that combined `ROLLUP` and `LIMIT` if `SQL_CALC_FOUND_ROWS` was given. (Bug #8617 [<http://bugs.mysql.com/8617>])
- **mysqldump** misinterpreted `'_'` and `'%'` characters in the names of tables to be dumped as wildcard characters. (Bug #9123 [<http://bugs.mysql.com/9123>])
- Made the `relay_log_space_limit` system variable show up in the output of `SHOW VARIABLES`. (Bug #7100 [<http://bugs.mysql.com/7100>])
- Use of `GROUP_CONCAT(x)` in a subquery, where `x` was an alias to a column in the outer query, resulted in a server crash. (Bug #8656 [<http://bugs.mysql.com/8656>])
- The `CHARSET()`, `COLLATION()`, and `COERCIBILITY()` functions sometimes returned `NULL`. `CHARSET()` and `COLLATION()` returned `NULL` when given any of these arguments that evaluated to `NULL`: A system function such as `DATABASE()`; a column value; and a user variable. Now `CHARSET()` and `COLLATION()` return the system character set and collation; the column character set and collation; and `binary`. `COERCIBILITY(NULL)` now returns ```ignorable``` coercibility rather than `NULL`. (Bug #9129 [<http://bugs.mysql.com/9129>])
- Expressions involving nested `CONCAT()` calls and character set conversion of string constants could return an incorrect result. (Bug #8785 [<http://bugs.mysql.com/8785>])

- The MEMORY storage engine did not properly increment an AUTO_INCREMENT column if there was a second composite index that included the column. (Bug #8489 [<http://bugs.mysql.com/8489>])
- Fixed a bug in the filesort routine such that killing a filesort could cause an assertion failure. (Bug #8799 [<http://bugs.mysql.com/8799>])
- REPAIR TABLE did not invalidate query results in the query cache that were generated from the table. (Bug #8480 [<http://bugs.mysql.com/8480>])
- If max_join_size was set, a query containing a subquery that exceeded the examined-rows limit could hang. (Bug #8726 [<http://bugs.mysql.com/8726>])
- Mixed-case database and table names in the grant tables were ignored for authentication if the lower_case_table_names system variable was set. GRANT will not create such privileges when lower_case_table_names is set, but it is possible to create them by direct manipulation of the grant tables, or that old grant records were present before setting the variable. (Bug #7989 [<http://bugs.mysql.com/7989>])
- AES_DECRYPT(*col_name*,*key*) could fail to return NULL for invalid values in *col_name*, if *col_name* was declared as NOT NULL. (Bug #8669 [<http://bugs.mysql.com/8669>])
- Ordering by unsigned expression (more complex than a column reference) was treating the value as signed, producing incorrectly sorted results. (Bug #7425 [<http://bugs.mysql.com/7425>])
- HAVING was treating unsigned columns as signed. (Bug #7425 [<http://bugs.mysql.com/7425>])
- Fixed a problem with boolean full-text searches on utf8 columns where a double quote in the search string caused a server crash. (Bug #8351 [<http://bugs.mysql.com/8351>])
- MIN(*col_name*) and MAX(*col_name*) could fail to produce the correct result if *col_name* was contained in multiple indexes and the optimizer did not choose the first index that contained the column. (Bug #8893 [<http://bugs.mysql.com/8893>])
- Table creation for a MyISAM table failed if DATA DIRECTORY or INDEX DIRECTORY options were given that specified the pathname to the database directory where the table files would be created by default. (Bug #8707 [<http://bugs.mysql.com/8707>])
- Fixed a problem with LIKE pattern-matching for strings with the cp1251_bin binary collation. (Bug #8560 [<http://bugs.mysql.com/8560>])
- A join on two tables failed when each contained a BIGINT UNSIGNED column that were compared when their values exceeded 2⁶³ - 1. The match failed and the join returned no rows. (Bug #8562 [<http://bugs.mysql.com/8562>])
- For a query with both GROUP BY and COUNT (DISTINCT) clauses and a FROM clause with a subquery, NULL was returned for any VARCHAR column selected by the subquery. (Bug #8218 [<http://bugs.mysql.com/8218>])
- Fixed an optimizer bug that caused incorrectly ordered result from a query that used a FULLTEXT index to retrieve rows and there was another index that was usable for ORDER BY. For such a query, EXPLAIN showed fulltext join type, but regular (not FULLTEXT) index in the Key column. (Bug #6635 [<http://bugs.mysql.com/6635>])
- For a statement string that contained multiple slow queries, only the last one would be written to the slow query log. (Bug #8475 [<http://bugs.mysql.com/8475>])
- When the server was started with --skip-name-resolve, specifying hostname values that included netmasks in GRANT statements did not work. (Bug #8471 [<http://bugs.mysql.com/8471>])
- The --set-character-set option for **myisamchk** was changed to --set-collation.

The value needed for specifying how to sort indexes is a collation name, not a character set name. (Bug #8349 [<http://bugs.mysql.com/8349>])

- Hostname matching didn't work if a netmask was specified for table-specific privileges. (Bug #3309 [<http://bugs.mysql.com/3309>])
- Binary data stored in BLOB or BINARY columns would be erroneously dumped if **mysqldump** was invoked with `--hex-blob` and `--skip-extended-insert` arguments. This happened if data contained characters larger than 0x7F (Bug #8830 [<http://bugs.mysql.com/8830>]).
- Corruption of MyISAM table indexes could occur with `TRUNCATE TABLE` if the table had already been opened. For example, this was possible if the table had been opened implicitly by selecting from a MERGE table that mapped to the MyISAM table. The server now issues an error message for `TRUNCATE TABLE` under these conditions. (Bug #8306 [<http://bugs.mysql.com/8306>])
- Fixed handling of table-name matching in **mysqlhotcopy** to accommodate `DBD::mysql 2.9003` and up (which implement identifier quoting). (Bug #8136 [<http://bugs.mysql.com/8136>])
- In the `mysql_real_escape_string()` C API function, when a multi-byte character is encountered that is illegal in the current character set, escape only the first byte, not each byte. This avoids creating a valid character from an invalid one. (Bug #8378 [<http://bugs.mysql.com/8378>])
- Fixed a problem with the `cp1250_czech_cs` collation that caused empty literal strings not to compare equal to empty character columns. (Bug #8840 [<http://bugs.mysql.com/8840>])
- Fixed a problem in index cost calculation that caused a `USE INDEX` or `FORCE INDEX` hint not to be used properly for a `LEFT JOIN` across indexed BLOB columns. (Bug #7520 [<http://bugs.mysql.com/7520>])
- The column type for `MAX(datetime_col)` was returned as `VARCHAR` rather than `DATE-TIME` if the query included a `GROUP BY` clause. (Bug #5615 [<http://bugs.mysql.com/5615>])
- `FOUND_ROWS()` returned an incorrect value for preceding `SELECT` statements that used no table or view. (Bug #6089 [<http://bugs.mysql.com/6089>])
- In string literals with an escape character (`'\'`) followed by a multi-byte character that has a second byte of `'\'`, the literal was not interpreted correctly. The next character now is escaped, not just the next byte. (Bug #8303 [<http://bugs.mysql.com/8303>])
- InnoDB: Work around a problem in AIX 5.1 patched with ML7 security patch: InnoDB would refuse to open its `ibdata` files, complaining about an operating system error 0.
- InnoDB: Fixed a memory corruption bug if one created a table with a primary key that contained at least two column prefixes. An example: `CREATE TABLE t(a char(100), b tinyblob, PRIMARY KEY(a(5), b(10)))`.
- InnoDB: Do not try to space-pad BLOB columns containing `ucs2` characters. This avoids an assertion failure that was introduced when fixing Bug #7350 [<http://bugs.mysql.com/7350>]. (Bug #8771 [<http://bugs.mysql.com/8771>])
- InnoDB: Fixed a bug: MySQL-4.1.8 - 4.1.10 could complain that an InnoDB table created with MySQL-3.23.49 or earlier was in the new compact InnoDB table format of 5.0.3 or later, and InnoDB would refuse to use that table. There is nothing wrong with the table, it is `mysqld` that is in error. Workaround: wait that 4.1.11 is released before doing an upgrade, or dump the table and recreate it with any MySQL version `>= 3.23.50` before upgrading.
- InnoDB: Honor the `--tmpdir` startup option when creating temporary files. Previously, InnoDB temporary files were always created in the temporary directory of the operating system. On Netware, InnoDB will continue to ignore `--tmpdir`. (Bug #5822 [<http://bugs.mysql.com/5822>])

- InnoDB: If MySQL wrote to its binlog, but for some reason `trx->update_undo` and `trx->insert_undo` were NULL in InnoDB, then `trx->commit_lsn` was garbage, and InnoDB could assert in the log flush of `trx_commit_complete_for_mysql()`. (Bug #9277 [<http://bugs.mysql.com/9277>])
- InnoDB: If InnoDB cannot allocate memory, keep retrying for 60 seconds before we intentionally crash `mysqld`; maybe the memory shortage is just temporary.
- InnoDB: If one used `LOCK TABLES`, created an InnoDB temp table, and did a multi-table update where a MyISAM table was the update table and the temp table was a read table, then InnoDB asserted in `row0sel.c` because `n_mysql_tables_in_use` was 0. Also, we remove the assertion altogether and just print an error to the `.err` log if this important consistency check fails. (Bug #8677 [<http://bugs.mysql.com/8677>])
- **mysqldump** now avoids writing `SET NAMES` to the dump output if the server is older than version 4.1 and would not understand that statement. (Bug #7997 [<http://bugs.mysql.com/7997>])
- Fixed a bug in **my_print_defaults** that made it ignore the `--defaults-extra-file` and `--defaults-file` options.
- Retrieving from a view defined as a `SELECT` that mixed `UNION ALL` and `UNION DISTINCT` resulted in a different result than retrieving from the original `SELECT`. (Bug #6565 [<http://bugs.mysql.com/6565>])
- Worked around a bug in support for NSS support in `glibc` when static linking is used and LDAP is one of the NSS sources. The workaround is to detect when the bug causes a segfault and issue a diagnostic message with information about the problem. (Bug #3037 [<http://bugs.mysql.com/3037>], Bug #4872 [<http://bugs.mysql.com/4872>])
- If the **mysql** prompt was configured to display the default database name, and that database was dropped, **mysql** did not update the prompt. (Bug #4802 [<http://bugs.mysql.com/4802>])
- **pererror** was printing a spurious extra line of output ("Error code ###: Unknown error ###" printed directly before the correct line with the error message). (Bug #8517 [<http://bugs.mysql.com/8517>])
- The `CHAR()` function was not ignoring NULL arguments, contrary to the documentation. (Bug #6317 [<http://bugs.mysql.com/6317>])
- Neither `SHOW ERRORS` nor `SHOW WARNINGS` were displaying Error-level messages. (Bug #6572 [<http://bugs.mysql.com/6572>])
- Creating a table using a name containing a character that is illegal in `character_set_client` resulted in the character being stripped from the name and no error. The character now is considered an error. (Bug #8041 [<http://bugs.mysql.com/8041>])
- Fixed a problem with the Cyrillic letters I and SHORT I being treated the same by the `utf8_general_ci` collation. (Bug #8385 [<http://bugs.mysql.com/8385>])
- The `MAX_CONNECTIONS_PER_HOUR` resource limit was not being reset hourly and thus imposed an absolute limit on number of connections per account until the server is restarted or the limits flushed. (Bug #8350 [<http://bugs.mysql.com/8350>])
- With a database was dropped with `lower_case_table_names=2`, tables in the database also were dropped but not being flushed properly from the table cache. If the database was recreated, the tables also would appear to have been recreated. (Bug #8355 [<http://bugs.mysql.com/8355>])
- Changed `mysql_server_end()` C API function to restore more variables to their initial state so that a subsequent call to `mysql_server_init()` would not cause a client program crash. (Bug #7344 [<http://bugs.mysql.com/7344>])
- Fixed a problem with accented letters improperly being treated as distinct with the

utf_general_ci collation. (Bug #7878 [<http://bugs.mysql.com/7878>])

- ENUM and SET columns in privilege tables incorrectly had a case-sensitive collation, resulting in failure of assignments of values that did not have the same lettercase as given in the column definitions. The collation was changed to be case insensitive. (Bug #7617 [<http://bugs.mysql.com/7617>])
- An expression that tested a case-insensitive character column against string constants that differed in lettercase could fail because the constants were treated as having a binary collation. (For example, WHERE city='London' AND city='london' could fail.) (Bug #7098 [<http://bugs.mysql.com/7098>], Bug #8690 [<http://bugs.mysql.com/8690>])
- The output of the STATUS (\s) command in **mysql** had the values for the server and client character sets reversed. (Bug #7571 [<http://bugs.mysql.com/7571>])
- If the slave was running with --replicate-*--table options which excluded one temporary table and included another, and the two tables were used in a single DROP TEMPORARY TABLE IF EXISTS statement, as the ones the master automatically writes to its binary log upon client's disconnection when client has not explicitly dropped these, the slave could forget to delete the included replicated temporary table. Only the slave needs to be upgraded. (Bug #8055 [<http://bugs.mysql.com/8055>])
- Treat user variables as having IMPLICIT derivation (coercibility) to avoid "Illegal mix of collations" errors when replicating user variables. (Bug #6676 [<http://bugs.mysql.com/6676>])
- When setting integer system variables to a negative value with SET VARIABLES, the value was treated as a positive value modulo 2^32. (Bug #6958 [<http://bugs.mysql.com/6958>])
- Fixed a bug in bundled readline library that caused segmentation fault in **mysql** when user entered Shift+Enter. (Bug #5672 [<http://bugs.mysql.com/5672>])
- Fix conversion of strings -> double to get higher accuracy for floating point values that are integers, like: 123.45E+02 (Bug #7840 [<http://bugs.mysql.com/7840>]).
- Fixed a bug in MATCH ... AGAINST in natural language mode that could cause a server crash if the FULLTEXT index was not used in a join (EXPLAIN did not show fulltext join mode) and the search query matched no rows in the table (Bug #8522 [<http://bugs.mysql.com/8522>]).
- Platform and architecture information in version information produced for --version option on Windows was always Win95/Win98 (i32). More accurately determine platform as Win32 or Win64 for 32-bit or 64-bit Windows, and architecture as ia32 for x86, ia64 for Itanium, and axp for Alpha. (Bug #4445 [<http://bugs.mysql.com/4445>])
- Fixed a rare race condition which could lead to FLUSH TABLES WITH READ LOCK hanging. (Bug #8682 [<http://bugs.mysql.com/8682>])
- Fixed a bug that caused the slave to stop on statements that produced an error on the master. (Bug #8412 [<http://bugs.mysql.com/8412>])
- If multiple semicolon-separated statements were received in a single packet, they were written to the binary log as a single event rather than as separate per-statement events. For a server serving as a replication master, this caused replication to fail when the event was sent to slave servers. (Bug #8436 [<http://bugs.mysql.com/8436>])

D.2.4. Changes in release 4.1.10 (12 Feb 2005)

Note: The security improvements related to creation of table files and to user-defined functions were made after MySQL 4.1.10 was released and are present in MySQL 4.1.10a. We would like to thank Stefano Di Paola <stefano.dipaola@wisec.it> for making us aware of these.

Functionality added or changed:

- Added back faster subquery execution from 4.1.8. This adds also back a bug from 4.1.8 in comparing NULL to the value of a subquery. See Section 1.7.7.4, “Open Bugs and Design Deficiencies in MySQL”.
- Security improvement: The server creates `.frm`, `.MYD`, `.MYI`, `.MRG`, `.ISD`, and `.ISM` table files only if a file with the same name does not already exist. Thanks to Stefano Di Paola <stefano.dipaola@wisec.it> for finding and informing us about this issue. (CAN-2005-0711 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2005-0711>])
- Security improvement: User-defined functions should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`, `xxx_deinit()`, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` functions. **mysqld** by default no longer loads UDFs unless they have at least one auxiliary symbol defined in addition to the main symbol. The `--allow-suspicious-udfs` option controls whether UDFs that have only an `xxx` symbol can be loaded. By default, the option is off. `mysqld` also checks UDF filenames when it reads them from the `mysql.func` table and rejects those that contain directory pathname separator characters. (It already checked names as given in `CREATE FUNCTION` statements.) See Section 27.2.3.1, “UDF Calling Sequences for simple functions”, Section 27.2.3.2, “UDF Calling Sequences for aggregate functions”, and Section 27.2.3.6, “User-defined Function Security Precautions”. Thanks to Stefano Di Paola <stefano.dipaola@wisec.it> for finding and informing us about this issue. (CAN-2005-0709 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2005-0709>], CAN-2005-0710 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2005-0710>])
- Setting the connection collation to a value different from the server collation followed by a `CREATE TABLE` statement that included a quoted default value resulted in a server crash. (Bug #8235 [<http://bugs.mysql.com/8235>])
- Thread stack size was increased from 192KB to 256KB on Linux/IA-64 (too small stack size was causing server crashes on some queries). (Bug #8391 [<http://bugs.mysql.com/8391>])
- From the Windows distribution, predefined accounts without passwords for remote users (“root@%”, “@%”) were removed (other distributions never had them).
- Added `mysql_library_init()` and `mysql_library_end()` as synonyms for the `mysql_server_init()` and `mysql_server_end()` C API functions. `mysql_library_init()` and `mysql_library_end()` are `#define` symbols, but the names more clearly indicate that they should be called when beginning and ending use of a MySQL C API library no matter whether the application uses `libmysqlclient` or `libmysqld`. (Bug #6149 [<http://bugs.mysql.com/6149>])
- The server now issues a warning when `lower_case_table_names=2` and the data directory is on a case-sensitive filesystem, just as when `lower_case_table_names=0` on a case-insensitive filesystem. (Bug #7887 [<http://bugs.mysql.com/7887>])
- The server now issues a warning to the error log when it encounters older tables that contain character columns that might be interpreted by newer servers to have a different column length. (Bug #6913 [<http://bugs.mysql.com/6913>]) See Section 2.10.2, “Upgrading from Version 4.0 to 4.1” for a discussion of this problem and what to do about it.
- InnoDB: When MySQL/InnoDB is compiled on Mac OS X 10.2 or earlier, detect the operating system version at run time and use the `fcntl()` file flush method on Mac OS X versions 10.3 and later. In Mac OS X, `fsync()` does not flush the write cache in the disk drive, but the special `fcntl()` does; however, the flush request is ignored by some external devices. Failure to flush the buffers may cause severe database corruption at power outages.
- InnoDB: A shared record lock (`LOCK_REC_NOT_GAP`) is now taken for a matching record in the foreign key check because inserts can be allowed into gaps.
- InnoDB: Relaxed locking in `INSERT...SELECT`, single table `UPDATE...SELECT` and single table `DELETE...SELECT` clauses when `innodb_locks_unsafe_for_binlog` is used and isolation level of the transaction is not serializable. InnoDB uses consistent read in these cases for a selected table.

Bugs fixed:

- `FOUND_ROWS()` returned an incorrect value after a `SELECT SQL_CALC_FOUND_ROWS DISTINCT` statement that selected constants and included `GROUP BY` and `LIMIT` clauses. (Bug #7945 [<http://bugs.mysql.com/7945>])
- Fixed a bug in cardinality estimations for `HASH` indexes of `TEMPORARY` tables created using `MEMORY` storage engine. As a result queries that were using this index (as shown by `EXPLAIN`) could have returned incorrect results. (Bug #8371 [<http://bugs.mysql.com/8371>])
- Corrected a problem with references to `DUAL` where statements such as `SELECT 1 AS a FROM DUAL` would succeed but statements such as `SELECT 1 AS a FROM DUAL LIMIT 1` would fail. (Bug #8023 [<http://bugs.mysql.com/8023>])
- Fixed a server crash caused by `DELETE FROM tbl_name ... WHERE ... ORDER BY tbl_name.col_name` when the `ORDER BY` column was qualified with the table name. (Bug #8392 [<http://bugs.mysql.com/8392>])
- **mysqld** had problems finding its language files if the `basedir` value was specified as a very long pathname. (Bug #8015 [<http://bugs.mysql.com/8015>])
- Updates were being written to the binary log when there were `binlog-do-db` or `binlog-ignore-db` options even when there was no current database, contrary to Section 5.10.4, “The Binary Log”. (Bug #6749 [<http://bugs.mysql.com/6749>])
- Fixed conversion of floating-point values to character fields when the absolute value of the float was less than 1, and also fixed calculation of length for negative values. (Bug #7774 [<http://bugs.mysql.com/7774>])
- Column headers in query results retrieved from the query cache could be corrupted when a non-4.1 client was served a result originally generated for a 4.1 client. The query cache was not keeping track of which client/server protocol was being used. (Bug #6511 [<http://bugs.mysql.com/6511>])
- Fixed `LOAD INDEX` statement to actually load index in memory. (Bug #8452 [<http://bugs.mysql.com/8452>])
- If multiple prepared statements were executed without retrieving their results, executing one of them again would cause the client program to crash. (Bug #8330 [<http://bugs.mysql.com/8330>])
- Non-numeric values inserted into a `YEAR` column were being stored as 2000 rather than as 0000. (Bug #6067 [<http://bugs.mysql.com/6067>])
- Fixed a failure of multiple-table updates to replicate properly on slave servers when `-replicate-*-table` options had been specified. (Bug #7011 [<http://bugs.mysql.com/7011>])
- `mysql_stmt_close()` C API function was not clearing an error indicator when a previous prepare call failed, causing subsequent invocations of error-retrieving calls to indicate spurious error values. (Bug #7990 [<http://bugs.mysql.com/7990>])
- Fixed failure of `CREATE TABLE ... LIKE` Windows when the source or destination table was located in a symlinked database directory. (Bug #6607 [<http://bugs.mysql.com/6607>])
- With `lower_case_table_names` set to 1, **mysqldump** on Windows could write the same table name in different lettercase for different SQL statements. Fixed so that consistent lettercase is used. (Bug #5185 [<http://bugs.mysql.com/5185>]) `HAVING` that referred to `RAND()` or a user-defined function in the `SELECT` part through an alias could cause a crash or wrong value. (Bug #8216 [<http://bugs.mysql.com/8216>])
- If one used `CONVERT_TZ()` function in `SELECT`, which in its turn was used in `CREATE TABLE` statements, then system time zone tables were added to list of tables joined in `SELECT` and

thus erroneous result was produced. (Bug #7899 [<http://bugs.mysql.com/7899>])

- Fixed a bug in `CONV()` function returning unsigned `BIGINT` number (third argument is positive, and return value does not fit in 32 bits). (Bug #7751 [<http://bugs.mysql.com/7751>])
- Fixed a failure of the `IN()` operator to return correct result if all values in the list were constants and some of them were using substring functions, for example, `LEFT()`, `RIGHT()`, or `MID()`.
- Fixed problem with `SHOW INDEX` reporting `Sub_part` values in bytes rather than characters for columns with a multi-byte character set. (Bug #7943 [<http://bugs.mysql.com/7943>])
- Fixed a crash in `CONVERT_TZ()` function when its second or third argument was from a `const` table (see Section 7.2.1, “`EXPLAIN` Syntax (Get Information About a `SELECT`)”). (Bug #7705 [<http://bugs.mysql.com/7705>])
- Correct a problem with `mysql_config`, which was failing to produce proper `zlib` option for linking under some circumstances. (Bug #6273 [<http://bugs.mysql.com/6273>])
- Fixed a problem with calculation of number of columns in row comparison against a subquery. (Bug #8020 [<http://bugs.mysql.com/8020>])
- Fixed erroneous output resulting from `SELECT DISTINCT` combined with a subquery and `GROUP BY`. (Bug #7946 [<http://bugs.mysql.com/7946>])
- Fixed server crash in comparing a nested row expression (for example `row(1, (2, 3))`) with a subquery. (Bug #8022 [<http://bugs.mysql.com/8022>])
- Fixed server crash resulting from certain correlated subqueries with forward references (referring to an alias defined later in the outer query). (Bug #8025 [<http://bugs.mysql.com/8025>])
- Fixed server crash resulting from re-execution of prepared statements containing subqueries. (Bug #8125 [<http://bugs.mysql.com/8125>])
- Removed a dependence of boolean full-text search on `--default-character-set` option. (Bug #8159 [<http://bugs.mysql.com/8159>])
- Fixed a crash in a boolean full-text search in certain joins. (Bug #8234 [<http://bugs.mysql.com/8234>])
- Fixed erroneous comparison where strings that began with `CHAR(31)` were considered equal to the empty string. (Bug #8134 [<http://bugs.mysql.com/8134>])
- Add description of `debug` command to `mysqladmin` help output. (Bug #8207 [<http://bugs.mysql.com/8207>])
- `pererror.exe` was always returning “Unknown error” on Windows. See Section 8.12, “`pererror`, Explaining Error Codes”. (Bug #7390 [<http://bugs.mysql.com/7390>])
- Modify `SET` statements produced by `mysqldump` to write quoted strings using single quotes rather than double quotes. This avoids problems if the dump file is reloaded while the `ANSI_QUOTES SQL` mode is in effect. (Bug #8148 [<http://bugs.mysql.com/8148>])
- Fixed a bug where `ALTER TABLE` improperly would accept an index on a `TIMESTAMP` column that `CREATE TABLE` would reject. (Bug #7884 [<http://bugs.mysql.com/7884>])
- Fixed a bug in multiple-table `UPDATE` statements that could cause spurious `Table '#sql_...' is full` errors if the number of rows to update is big enough. (Bug #7788 [<http://bugs.mysql.com/7788>])
- Fixed a problem where `SHOW INDEX` on a `MERGE` table could crash a debugging version of the server. (Bug #7377 [<http://bugs.mysql.com/7377>])
- Fixed a problem where adding an `ORDER BY` clause for an indexed column would cause a `SE-`

LECT to return an empty result. (Bug #7331 [<http://bugs.mysql.com/7331>])

- Fixed a problem where ALTER TABLE on a TEMPORARY table with a mixed-lettercase name could cause the table to disappear when lower_case_table_names was set to 2. (Bug #7261 [<http://bugs.mysql.com/7261>])
- Fixed a problem with key cache statistics being reported incorrectly by the server after receipt of a SIGHUP signal. (Bug #4285 [<http://bugs.mysql.com/4285>])
- Fixed a problem that caused mysql_stmt_prepare() to be very slow when used in client programs on Windows. (Bug #5787 [<http://bugs.mysql.com/5787>])
- For indexes, SHOW CREATE TABLE now displays the index type even if it is the default, for storage engines that support multiple index types. (Bug #7235 [<http://bugs.mysql.com/7235>])
- Fixed a bug where the use of GROUP_CONCAT() with HAVING caused a server crash. (Bug #7769 [<http://bugs.mysql.com/7769>])
- Fixed a bug where comparing the result of a subquery to a non-existent column caused a server crash on Windows. (Bug #7885 [<http://bugs.mysql.com/7885>])
- Fixed a bug which caused TIMEDIFF() function to return wrong results if one of its arguments had non-zero microsecond part (Bug #7586 [<http://bugs.mysql.com/7586>]).
- Fixed a bug which caused TIMESTAMP columns with display width specified to be not identical to DATETIME columns when server was run in MAXDB mode (Bug #7418 [<http://bugs.mysql.com/7418>]).
- Fixed a bug in UNION statements that resulted in the wrong number of the examined rows reported in the slow query log.
- Fixed a bug in a combination of -not and trunc* operators of full-text search. Using more than one truncated negative search term, was causing empty result set.
- InnoDB: Fixed a bug introduced in 4.1.9 to the Windows version if you used innodb_file_per_table. **mysqld** would stop and complain about Windows error number 87 in a file operation. (See the Bugs database or the 4.1.9 change notes about a workaround for that bug in 4.1.9). (Bug #8021 [<http://bugs.mysql.com/8021>])
- InnoDB: Corrected the handling of trailing spaces in the ucs2 character set. (Bug #7350 [<http://bugs.mysql.com/7350>])
- InnoDB: Use native tmpfile() function on Netware. All InnoDB temporary files are created under sys:\tmp. Previously, InnoDB temporary files were never deleted on Netware.
- InnoDB: Fix a race condition that could cause the assertion space->n_pending_flushes == 0 to fail in fil0fil.c, in fil_space_free(), in DROP TABLE or in ALTER TABLE.
- InnoDB: ALTER TABLE ... ADD CONSTRAINT PRIMARY KEY ... complained about bad foreign key definition. (Bug #7831 [<http://bugs.mysql.com/7831>])
- InnoDB: Fix a theoretical hang over the adaptive hash latch in InnoDB if one runs INSERT ... SELECT ... (binlog not enabled), or a multi-table UPDATE or DELETE, and only the read tables are InnoDB type, the rest are MyISAM. (Bug #7879 [<http://bugs.mysql.com/7879>])
- Fixed a bug in max_heap_table_size handling, that resulted in Table is full error when the table was still smaller than the limit. (Bug #7791 [<http://bugs.mysql.com/7791>]).
- Fixed a symlink vulnerability in the **mysqlaccess** script. Reported by Javier Fernandez-Sanguino Pena and Debian Security Audit Team [<http://www.debian.org/security/audit>]. (CAN-2005-0004 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2005-0004>])
- **mysqlbinlog** forgot to add backquotes around the collation of user variables (causing later pars-

ing problems as BINARY is a reserved word). (Bug #7793 [<http://bugs.mysql.com/7793>])

- Ensured that **mysqldump --single-transaction** sets its transaction isolation level to REPEATABLE READ before proceeding (otherwise if the MySQL server was configured to run with a default isolation level lower than REPEATABLE READ it could give an inconsistent dump). (Bug #7850 [<http://bugs.mysql.com/7850>])
- Changed **mysql** client so that including \p as part of a prompt command uses the name of the shared memory connection when the connection is using shared memory. (Bug #7922 [<http://bugs.mysql.com/7922>])
- Fixed a problem in the server where executing a multi-statement query more than once with the query cache active could yield incorrect result sets. (Bug #7966 [<http://bugs.mysql.com/7966>])
- Fixed that a 4.1.10 slave can connect to a master < 3.23.50 without hanging (the reason for the hang is a bug in these quite old masters -- SELECT @@unknown_var hangs them -- which was fixed in MySQL 3.23.50). (Bug #7965 [<http://bugs.mysql.com/7965>])
- Fixed a bug where MySQL was allowing concurrent updates (inserts, deletes) to a table if binary logging is enabled. Changed to ensure that all updates are executed in a serialized fashion, because they are executed serialized when binlog is replayed. (Bug #7879 [<http://bugs.mysql.com/7879>])

D.2.5. Changes in release 4.1.9 (11 Jan 2005)

Functionality added or changed:

- **mysqld_safe** no longer tests for the presence of the data directory when using a relatively located server binary. It just assumes the directory is there, and fails to start up if it is not. This allows the data directory location to be specified on the command line, and avoids running a server binary that was not intended. (Bug #7249 [<http://bugs.mysql.com/7249>])
- The naming scheme of the Windows installation packages has changed slightly:
 - The platform suffix was changed from -win to -win32
 - The product descriptions -noinstall and -essential have been moved in front of the version number

Examples: `mysql-essential-4.1.9-win32.msi`, `mysql-noinstall-4.1.9-win32.zip` See Section 2.3, "Installing MySQL on Windows".

- The Mac OS X 10.3 installation disk images now include a MySQL Preference Pane for the Mac OS X Control Panel that enables the user to start and stop the MySQL server via the GUI and activate and deactivate the automatic MySQL server startup on bootup.
- The MySQL-shared-compat Linux RPM now includes the 3.23 as well as the 4.0 `libmysqlclient.so` shared libraries. (Bug #6342 [<http://bugs.mysql.com/6342>])
- `Seconds_Behind_Master` is NULL (which means ``unknown'') if the slave SQL thread is not running, or if the slave I/O thread is not running or not connected to master. It is zero if the SQL thread has caught up with the I/O thread. It no longer grows indefinitely if the master is idle.
- InnoDB: Do not acquire an internal InnoDB table lock in `LOCK TABLES` if `AUTOCOMMIT=1`. This helps in porting old MyISAM applications to InnoDB. InnoDB table locks in that case caused deadlocks very easily.
- InnoDB: Print a more descriptive error and refuse to start InnoDB if the size of `ibdata` files is smaller than what is stored in the tablespace header; `innodb_force_recovery` overrides this.

- The MySQL server aborts immediately instead of simply issuing a warning if it is started with the `--log-bin` option but cannot initialize the binary log at startup (that is, an error occurs when writing to the binary log file or binary log index file).
- The binary log file and binary log index file now behave like MyISAM when there is a "disk full" or "quota exceeded" error. See Section A.4.3, "How MySQL Handles a Full Disk".

Bugs fixed:

- Fixed problem where running `mysql_fix_privilege_tables` could result in grant table columns with too-short lengths if the server character set had been set to a multi-byte character set first. (Bug #7539 [<http://bugs.mysql.com/7539>])
- InnoDB: Fixed the **critical bug** if you enabled `innodb_file_per_table` in `my.cnf`. If you shut down `mysqld`, records could disappear from the secondary indexes of a table. Unfortunately, on Windows a new Bug #8021 [<http://bugs.mysql.com/8021>] was introduced. Windows users of `innodb_file_per_table` should put a line `innodb_flush_method=unbuffered` to their `my.cnf` or `my.ini` to work around 8021. (Bug #7496 [<http://bugs.mysql.com/7496>])
- InnoDB: Fixed a bug: 32-bit `mysqld` binaries built on HP-UX-11 did not work with InnoDB files greater than 2 GB in size. (Bug #6189 [<http://bugs.mysql.com/6189>])
- InnoDB: Return a sensible error code from `DISCARD TABLESPACE` if it fails because the table is referenced by a `FOREIGN KEY`.
- InnoDB: Fixed a bug: InnoDB failed to drop a table in the background drop queue if the table was referenced by a `FOREIGN KEY` constraint.
- InnoDB: Fixed a bug: if we dropped a table where an `INSERT` was waiting for a lock to check a `FOREIGN KEY` constraint, then an assertion would fail in `lock_reset_all_on_table()`.
- InnoDB: Fix a little bug: we looked at the physical size of a stored SQL `NULL` value from a wrong field in the index; this has probably caused no bugs visible to the user. It caused only some extra space to be used in some rare cases.
- InnoDB: Use the `fcntl()` file flush method on Mac OS X versions 10.3 and up. Apple had disabled `fsync()` in Mac OS X for internal disk drives, which caused corruption at power outages.
- `mysqladmin password` now checks whether the server has `--old-passwords` turned on or predates 4.1 and uses the old-format password if so. (Bug #7451 [<http://bugs.mysql.com/7451>])
- Added a `--default-character-set` option to `mysqladmin` to avoid problems when the default character set is not `latin1`. (Bug #7524 [<http://bugs.mysql.com/7524>])
- Fix a problem with truncation of `FLOAT` values. (Bug #7361 [<http://bugs.mysql.com/7361>])
- Fixed a bug in `PROCEDURE ANALYSE()`, which did not quote some `ENUM` values properly. (Bug #2813 [<http://bugs.mysql.com/2813>])
- Fixed a bug that caused incorrect results for complex datetime expressions containing casts of datetime values to `TIME` or `DATE` values. (Bug #6914 [<http://bugs.mysql.com/6914>])
- Include compression library flags in the output from `mysql_config --lib_r`. (Bug #7021 [<http://bugs.mysql.com/7021>])
- Corrected a problem with `mysql_config` not producing all relevant flags from `CFLAGS`. (Bug #6964 [<http://bugs.mysql.com/6964>])
- Corrected a problem with `mysqld_safe` not properly capturing output from `ps`. (Bug #5878

[<http://bugs.mysql.com/5878>])

- Fixed a bug that caused a linking failure when linking both the MySQL client library and IMAP library. (Bug #7428 [<http://bugs.mysql.com/7428>])
- Fixed table corruption bug when using `INSERT DELAYED` with prepared statements.
- Fixed a bug that caused microseconds to be gobbled from the string result of the `STR_TO_DATE` function, if there is some other specifier in the format string following `%f`. (Bug #7458 [<http://bugs.mysql.com/7458>])
- Made the MySQL server accept executing `SHOW CREATE DATABASE` even if the connection has an open transaction or locked tables. Refusing it made **mysqldump --single-transaction** sometimes fail to print a complete `CREATE DATABASE` statement for some dumped databases. (Bug #7358 [<http://bugs.mysql.com/7358>])
- Fixed that, when encountering a ```disk full"` or ```quota exceeded"` write error, MyISAM sometimes didn't sleep and retry the write, thus resulting in a corrupted table. (Bug #7714 [<http://bugs.mysql.com/7714>])
- Fixed that `--expire-log-days` was not honored if using only transactions. (Bug #7236 [<http://bugs.mysql.com/7236>])
- Fixed that a slave could crash after replicating many `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `REPAIR TABLE` statements from the master. (Bug #6461 [<http://bugs.mysql.com/6461>], Bug #7658 [<http://bugs.mysql.com/7658>])

D.2.6. Changes in release 4.1.8 (14 Dec 2004)

Note: Due to a **libtool**-related bug in the source distribution, the creation of shared `libmysql-client` libraries was not possible (the resulting files were missing the `.so` file name extension). The file `ltmain.sh` was updated to fix this problem and the resulting source distribution was released as `mysql-4.1.8a.tar.gz`. This modification did not affect the binary packages. (Bug #7401 [<http://bugs.mysql.com/7401>])

Functionality added or changed:

- Automatic character set conversion formerly was done for operations that mix a column and a string such as assigning a string to a column, when this was possible without loss of information. Automatic conversion for operations that mix columns and strings has been expanded to cover many functions (such as `CONCAT()`) and assignment operators. This reduces the frequency of illegal mix of collations errors.
- For `ALTER DATABASE`, the database name now can be omitted to apply the change to the default database.
- Added `WITH CONSISTENT SNAPSHOT` clause to `START TRANSACTION` to begin a transaction with a consistent read.
- Added `--order-by-primary` to **mysqldump**, to sort each table's data in a dump file. This may be useful when dumping a MyISAM table which will be loaded into an InnoDB table. Dumping a MyISAM table with this option is considerably slower than without.
- InnoDB: Do not periodically write `SHOW INNODB STATUS` information to a temporary file unless the configuration option `innodb_status_file=1` is set.
- InnoDB: Commit after every 10,000 copied rows when executing `ALTER TABLE`. This makes it much faster to recover from an aborted `ALTER TABLE` or `OPTIMIZE TABLE`.
- `FULLTEXT` index block size is changed to be 1024 instead of 2048.

- Added `--disable-log-bin` option to **mysqlbinlog**. Using this option you can disable binary logging for the statements produced by **mysqlbinlog**. That is, `mysqlbinlog --disable-log-bin <file_name> | mysql` won't write any statements to the MySQL server binary log.
- The `--master-data` option for **mysqldump** now takes an optional argument of 1 or 2 to produce a non-commented or commented `CHANGE MASTER TO` statement. The default is 1 for backward compatibility.
- `mysqldump --single-transaction --master-data` now is able to take an online (non-blocking) dump of InnoDB and report the corresponding binary log coordinates. This makes a backup suitable for point-in-time recovery, roll-forward or replication slave creation. See Section 8.8, "The **mysqldump** Database Backup Program".
- Added `--lock-all-tables` to **mysqldump** to lock all tables by acquiring a global read lock.
- Added `--hex-blob` option to **mysqldump** for dumping binary string columns using hexadecimal notation.
- Added `mysql_hex_string()` C API function that hex-encodes a string.
- In the normal log MySQL now prints the log position for `Binlog Dump` requests.
- Added `[mysql_cluster]` section to `my.cnf` file for configuration settings specific to MySQL Cluster. `ndb-connectstring` variable moved here.
- A connection doing a rollback now displays "Rolling back" in the `State` column of `SHOW PROCESSLIST`.
- `mysqlbinlog` now prints an informative commented line (thread id, timestamp, server id, etc) before each `LOAD DATA INFILE`, like it does for other queries; unless `--short-form` is used.

Bugs fixed:

- Fixed incorrect referencing to column by name from subquery to outer query in case of using temporary table by outer query and placing subquery in the `WHERE` clause. (Bug #7079 [<http://bugs.mysql.com/7079>])
- Fixed a bug in authentication code that allowed a malicious user to crash the server with specially crafted packets (using a modified client library). (Bug #7187 [<http://bugs.mysql.com/7187>])
- Fixed a crashing bug in a string function `LEFT`, when this function is part of the expression which is used as `GROUP BY` field. (Bug #7101 [<http://bugs.mysql.com/7101>])
- Fixed bug which caused MySQL to require privileges on system time zone description tables for implicit access to them (i.e. if one set `time_zone` variable or used `CONVERT_TZ()` function) in case when some table-level or column-level privileges existed. (Bug #6765 [<http://bugs.mysql.com/6765>])
- `mysql_stmt_data_seek(stmt, 0)` now rewinds a counter and enables buffered rows to be re-fetched on the client side. (Bug #6996 [<http://bugs.mysql.com/6996>])
- Fixed an insufficient privilege check in `SHOW CREATE TABLE` command. (Bug #7043 [<http://bugs.mysql.com/7043>])
- Fixed a rare memory corruption (that resulted in a crash) in `MATCH ... AGAINST` on columns that use multi-byte character sets. (Bug #6269 [<http://bugs.mysql.com/6269>])
- Fixed `NULL` processing in `ALL/SOME` subqueries. (Bug #6247 [<http://bugs.mysql.com/6247>])

- Fixed execution of complex queries with subqueries. (Bug #6406 [<http://bugs.mysql.com/6406>], Bug #6841 [<http://bugs.mysql.com/6841>])
- Fixed initialization of some internal structures for first execution. (Bug #6517 [<http://bugs.mysql.com/6517>])
- Backported a fix for the full-text interface from MySQL 5.0. (Bug #6523 [<http://bugs.mysql.com/6523>])
- Fixed NULL value handling in case of empty results in subqueries. (Bug #6806 [<http://bugs.mysql.com/6806>])
- Prevent adding CREATE TABLE ... SELECT query to the binary log when the insertion of new records partially failed. (Bug #6682 [<http://bugs.mysql.com/6682>])
- INSERT ... SELECT no longer reports spurious "column truncated" warnings (Bug #6284 [<http://bugs.mysql.com/6284>])
- Fixed a bug that could cause "Record has changed since last read in table" error message in some queries on HEAP tables that contain only one row. (Bug #6748 [<http://bugs.mysql.com/6748>])
- **mysqld_safe** was in many cases ignoring any --no-defaults, --defaults-file, or --defaults-extra-file arguments. Those arguments are now honored, and this may change what options are passed to **mysqld** in some installations.
- The server was interpreting CHAR BINARY and VARCHAR BINARY columns from 4.0 tables as having the BINARY and VARBINARY data types. Now they are interpreted as CHAR and VARCHAR columns that have the binary collation of the column's character set. (This is the same way that CHAR BINARY and VARCHAR BINARY are handled for new tables created in 4.1.)
- Fixed spurious "duplicate key" error from REPLACE or INSERT ... ON DUPLICATE KEY UPDATE statements performing multiple-row insert in the table that had unique and full-text indexes. (Bug #6784 [<http://bugs.mysql.com/6784>])
- Fixed a bug in execution of subqueries in SET and DO statements which caused wrong results to be returned from subsequent queries. (Bug #6462 [<http://bugs.mysql.com/6462>])
- Fixed a bug that allowed server to accept datetime values with wrong year part. The server now also performs same checks for datetime values passed through MYSQL_TIME structures as for datetime values passed as strings. (Bug #6266 [<http://bugs.mysql.com/6266>])
- Fixed a bug with INSERT for a table with FULLTEXT indexes. Under rare circumstances, this could result in a corrupted table if words of different lengths may be considered equal. This is possible in some collations, for example, in utf8_general_ci or latin1_german2_ci. (Bug #6265 [<http://bugs.mysql.com/6265>])
- InnoDB: Do not intentionally crash mysqld if the buffer pool is exhausted by the lock table; return error 1206 instead. Do not intentionally crash mysqld if we cannot allocate the memory for the InnoDB buffer pool. (Bug #6817 [<http://bugs.mysql.com/6817>]) (Bug #6827 [<http://bugs.mysql.com/6827>])
- InnoDB: Let InnoDB's FOREIGN KEY parser to remove the latin1 character 0xA0 from the end of an unquoted identifier. The EMS MySQL Manager in ALTER TABLE adds that character after a table name, which caused error 121 when we tried to add a new constraint.
- InnoDB: Refuse to open new-style tables created with MySQL 5.0.3 or later. (Bug #7089 [<http://bugs.mysql.com/7089>])
- InnoDB: Do not call rewind() when displaying SHOW INNODB STATUS information on stderr.
- InnoDB: Made the foreign key parser better aware of quotes. (Bug #6340)

[<http://bugs.mysql.com/6340>])

- InnoDB: If one used `INSERT IGNORE` to insert several rows at a time, and the first inserts were ignored because of a duplicate key collision, then InnoDB in a replication slave assigned `AUTO_INCREMENT` values 1 bigger than in the master. This broke the MySQL replication. (Bug #6287 [<http://bugs.mysql.com/6287>])
- InnoDB: Fixed a bug: InnoDB ignored in `innodb_data_file_path` the max specification in `:autoextend:max:2000M`. This bug was introduced in 4.1.1.
- InnoDB: Fixed a bug: `innodb_locks_unsafe_for_binlog` still uses next-key locking (Bug #6747 [<http://bugs.mysql.com/6747>]). InnoDB used next-key locking when record matched completely to search tuple. This unnecessary next-key locking is now removed when `innodb_locks_unsafe_for_binlog` option is used.
- InnoDB: Fix two hangs: `FOREIGN KEY` constraints treated table and database names as case-insensitive. `RENAME TABLE t TO T` would hang in an endless loop if `t` had a foreign key constraint defined on it. Fix also a hang over the dictionary mutex that would occur if one tried in `ALTER TABLE` or `RENAME TABLE` to create a foreign key constraint name that collided with another existing name. (Bug #3478 [<http://bugs.mysql.com/3478>])
- If `STMT_ATTR_UPDATE_MAX_LENGTH` is set for a prepared statement, `mysql_stmt_store_result()` updates `field->max_length` for numeric columns as well. (Bug#6096)
- Prepared statements now handle `ZEROFILL` when converting integer to string.
- Fixed crash when a call to `mysql_stmt_store_result()` occurred without a preceding call to `mysql_stmt_bind_result()`.
- Fixed crash in prepared statements when using `SELECT * FROM t1 NATURAL JOIN t2...`
- Fixed crash in prepared statements when using `SELECT ... PROCEDURE`.
- Fixed crash in prepared statements when using subqueries.
- `GROUP_CONCAT(...ORDER BY)` when used with prepared statements gave wrong sorting order.
- `CREATE TABLE created_table` didn't signal when table was created. This could cause a `DROP TABLE created_table` in another thread to wait "forever".
- Server warnings now are reset when you execute a prepared statement.
- Improved performance of identifier comparisons (if many tables or columns are specified).
- `OPTIMIZE TABLE`, `REPAIR TABLE`, and `ANALYZE TABLE` are now replicated without any error code in the binary log. (Bug #5551 [<http://bugs.mysql.com/5551>])
- `LOAD DATA INFILE` now works with option `replicate-rewrite-db`. (Bug #6353 [<http://bugs.mysql.com/6353>])
- Fixed a bug which caused a crash when only the slave I/O thread was stopped and started. (Bug #6148 [<http://bugs.mysql.com/6148>])
- Changed semantics of `CREATE/ALTER/DROP DATABASE` statements so that replication of `CREATE DATABASE` is possible when using `--binlog-do-db` and `--binlog-ignore-db`. (Bug #6391 [<http://bugs.mysql.com/6391>])
- If a connection had an open transaction but had done no updates to transactional tables (for example if had just done a `SELECT FOR UPDATE` then executed a non-transactional update, that update automatically committed the transaction (thus releasing InnoDB's row-level locks etc). (Bug #5714 [<http://bugs.mysql.com/5714>])

- If a connection was interrupted by a network error and did a rollback, the network error code got stored into the BEGIN and ROLLBACK binary log events; that caused superfluous slave stops. (Bug #6522 [<http://bugs.mysql.com/6522>])
- A sequence of BEGIN (or SET AUTOCOMMIT=0), FLUSH TABLES WITH READ LOCK, transactional update, COMMIT, FLUSH TABLES WITH READ LOCK could hang the connection forever and possibly the MySQL server itself. This happened for example when running the innobackup script several times. (Bug #6732 [<http://bugs.mysql.com/6732>])
- **mysqlbinlog** did not print SET PSEUDO_THREAD_ID statements in front of LOAD DATA INFILE statements inserting into temporary tables, thus causing potential problems when rolling forward these statements after restoring a backup. (Bug #6671 [<http://bugs.mysql.com/6671>])

D.2.7. Changes in release 4.1.7 (23 Oct 2004: Production)

Functionality added or changed:

- MOD() no longer rounds arguments with a fractional part to integers. Now it returns exact remainder after division. (Bug #6138 [<http://bugs.mysql.com/6138>])
- InnoDB: Added a startup option and settable system variable innodb_table_locks for making LOCK TABLE acquire also InnoDB locks. The default value is 1, which means that LOCK TABLES causes also InnoDB internally to take a table lock. In applications using AUTOCOMMIT=1 and LOCK TABLES, InnoDB's internal table locks that were added in 4.0.20 and 4.1.2 can cause deadlocks. You can set innodb_table_locks=0 in my.cnf to remove that problem. (Bug #3299 [<http://bugs.mysql.com/3299>], Bug #5998 [<http://bugs.mysql.com/5998>])
- See Section 15.17, “Restrictions on InnoDB Tables”. (Bug #3299 [<http://bugs.mysql.com/3299>], Bug #5998 [<http://bugs.mysql.com/5998>]) InnoDB: SHOW TABLE STATUS now shows the creation time of the table for InnoDB. Note that this timestamp might not be the correct time because, e.g., ALTER TABLE changes this timestamp.
- InnoDB: If innodb_thread_concurrency would be exceeded, let a thread sleep 10 ms before entering the FIFO queue; previously, the value was 50 ms.

Bugs fixed:

- Fixed a bug with FOUND_ROWS() used together with LIMIT clause in prepared statements. (Bug#6088)
- Fixed a bug with NATURAL JOIN in prepared statements. (Bug#6046).
- Fixed a bug in join of tables from different databases having columns with identical names (prepared statements). (Bug#6050)
- Now implicit access to system time zone description tables (which happens when you set time_zone variable or use CONVERT_TZ() function) does not require any privileges. (Bug #6116 [<http://bugs.mysql.com/6116>])
- Fixed a bug which caused the server to crash when the deprecated libmysqlclient function mysql_create_db() was called. (Bug #6081 [<http://bugs.mysql.com/6081>])
- Fixed REVOKE ALL PRIVILEGES, GRANT OPTION FROM user so that all privileges are revoked correctly. (Bug #5831 [<http://bugs.mysql.com/5831>]). This corrects a case that the fix in 4.1.6 could miss.

- Fixed crash when selecting from a HEAP table with `key_column IS NOT NULL`. This could also cause a crash if not all index parts were used. (Bug #6082 [<http://bugs.mysql.com/6082>])
- Fixed a bug that could cause MyISAM index corruption when key values start with character codes below BLANK. This was caused by the new key sort order in 4.1. (Bug #6151 [<http://bugs.mysql.com/6151>])
- InnoDB: Fixed a bug in `LOAD DATA INFILE...REPLACE` printing duplicate key error when executing the same load query several times. (Bug #5835 [<http://bugs.mysql.com/5835>])
- Fixed a bug in the prepared statements protocol when wrong metadata was sent for SELECT statements not returning a result set (such as `SELECT ... INTO OUTFILE`). (Bug #6059 [<http://bugs.mysql.com/6059>])
- Fixed bug which allowed one to circumvent missing UPDATE privilege if one had INSERT and SELECT privileges for table with primary key. (Bug #6173 [<http://bugs.mysql.com/6173>])
- Fixed a bug in `libmysqlclient` with wrong conversion of negative time values to strings. (Bug #6049 [<http://bugs.mysql.com/6049>]).
- Fixed a bug in `libmysqlclient` with wrong conversion of zero date values (0000-00-00) to strings. (Bug #6058 [<http://bugs.mysql.com/6058>])
- Fixed a bug that caused the server to crash on attempt to prepare a statement with `RAND(?)`. (Bug #5985 [<http://bugs.mysql.com/5985>])
- Fixed a bug with handling of DATE, TIME, and DATETIME columns in the binary protocol. The problem is compiler-specific and could have been observed on HP-UX, AIX, Solaris9, when compiling with native compiler. (Bug #6025 [<http://bugs.mysql.com/6025>])
- Fixed a bug with handling of TINYINT columns in the binary protocol. The problem is specific to platforms where the C compiler has the `char` data type unsigned by default. (Bug #6024 [<http://bugs.mysql.com/6024>])
- InnoDB: Fixed problem introduced in MySQL 4.0.21 where a connection starting a transaction, doing updates, then `FLUSH TABLES WITH READ LOCK`, then `COMMIT`, would cause replication slaves to stop (complaining about error 1223). Bug surfaced when using the InnoDB `innobackup` script. (Bug #5949 [<http://bugs.mysql.com/5949>])
- InnoDB: Release the dictionary latch during a long cascaded FOREIGN KEY operation, so that we do not starve other users doing `CREATE TABLE` or other DDL operation. This caused a notorious 'Long semaphore wait' message to be printed to the `.err` log. (Bug #5961 [<http://bugs.mysql.com/5961>])

D.2.8. Changes in release 4.1.6 (10 Oct 2004)

Functionality added or changed:

- Added option `--sigint-ignore` to the `mysql` command line client to make it ignore SIGINT signals (typically the result of the user pressing Control-C).
- InnoDB: Added the startup option and settable global variable `innodb_max_purge_lag` for delaying INSERT, UPDATE and DELETE operations when the purge operations are lagging. The default value of this parameter is zero, meaning that there are no delays. See Section 15.13, "Implementation of Multi-Versioning".
- InnoDB: The `innodb_autoextend_increment` startup option that was introduced in release 4.1.5 was made a settable global variable. (Bug #5736 [<http://bugs.mysql.com/5736>])
- InnoDB: If `DROP TABLE` is invoked on an InnoDB table for which the `.ibd` file is missing, print to error log that the table was removed from the InnoDB data dictionary, and allow

MySQL to delete the `.frm` file. Maybe `DROP TABLE` should issue a warning in this case.

- `TIMESTAMP` columns now can store `NULL` values. To create such a column, you must explicitly specify the `NULL` attribute in the column specification. (Unlike all other column types, `TIMESTAMP` columns are `NOT NULL` by default.)
- Now if `ALTER TABLE` converts one `AUTO_INCREMENT` column to another `AUTO_INCREMENT` column it preserves zero values (this includes the case that we don't change such column at all).
- Now if `ALTER TABLE` converts some column to `TIMESTAMP NOT NULL` column it converts `NULL` values to current timestamp value (One can still get old behavior by setting system `TIMESTAMP` variable to zero).
- On Windows, the MySQL configuration files included in the package now use `.ini` instead of `.cnf` as the file name suffix.

Bugs fixed:

- Fixed a bug that caused the server to crash on attempt to execute a prepared statement with a subselect inside a boolean expression. (Bug #5987 [<http://bugs.mysql.com/5987>])
- Fixed a bug that caused the server to sometimes choose non-optimal execution plan for a prepared statement executed with changed placeholder values. (Bug #6042 [<http://bugs.mysql.com/6042>])
- InnoDB: Make the check for excessive semaphore waits tolerate glitches in the system clock (do not crash the server if the system time is adjusted while InnoDB is under load.). (Bug #5898 [<http://bugs.mysql.com/5898>])
- InnoDB: Fixed a bug in the InnoDB `FOREIGN KEY` parser that prevented `ALTER TABLE` of tables containing '#' in their names. (Bug #5856 [<http://bugs.mysql.com/5856>])
- InnoDB: Fixed a bug that prevented `ALTER TABLE t DISCARD TABLESPACE` from working. (Bug #5851 [<http://bugs.mysql.com/5851>])
- InnoDB: `SHOW CREATE TABLE` now obeys the `SET SQL_MODE=ANSI` and `SET SQL_QUOTE_SHOW_CREATE=0` settings. (Bug #5292 [<http://bugs.mysql.com/5292>])
- InnoDB: Fixed a bug that caused `CREATE TEMPORARY TABLE ... ENGINE=InnoDB` to terminate **mysqld** when running in `innodb_file_per_table` mode. Per-table tablespaces for temporary tables from now on are created in the temporary directory of **mysqld**. (Bug #5137 [<http://bugs.mysql.com/5137>])
- InnoDB: Fixed some (not all) UTF-8 bugs in column prefix indexes. (Bug #5975 [<http://bugs.mysql.com/5975>])
- InnoDB: If one updated a column so that its size changed, or updated it to an externally stored (`TEXT` or `BLOB`) value, then `ANOTHER` externally stored column would show up as 512 bytes of good data + 20 bytes of garbage in a consistent read that fetched the old version of the row. (Bug #5960 [<http://bugs.mysql.com/5960>])
- InnoDB: Change error code to `HA_ERR_ROW_IS_REFERENCED` if we cannot `DROP` a parent table referenced by a `FOREIGN KEY` constraint; this error number is less misleading than the previous number `HA_ERR_CANNOT_ADD_FOREIGN`, but misleading still. (Bug #6202 [<http://bugs.mysql.com/6202>])
- Fixed `REVOKE ALL PRIVILEGES, GRANT OPTION FROM user` so that all privileges are revoked correctly. (Bug #5831 [<http://bugs.mysql.com/5831>])
- Fixed a bug that caused the server to crash when character set conversion was implicitly used in prepared mode; for example, as in `'abc' LIKE CONVERT('abc' as utf8)`. (Bug

#5688 [<http://bugs.mysql.com/5688>])

- The `mysql_change_user()` C API function now frees all prepared statements associated with the connection. (Bug #5315 [<http://bugs.mysql.com/5315>])
- Fixed a bug when inserting NULL into an AUTO_INCREMENT column failed, when using prepared statements. (Bug #5510 [<http://bugs.mysql.com/5510>])
- Fixed slave SQL thread so that the SET COLLATION_SERVER... statements it replicates don't advance its position (so that if it gets interrupted before the actual update query, it later re-does the SET). (Bug #5705 [<http://bugs.mysql.com/5705>])
- Fixed that if the slave SQL thread found a syntax error in a query (which should be rare, as the master parsed it successfully), it stops. (Bug #5711 [<http://bugs.mysql.com/5711>])
- Fixed that if a write to a MyISAM table fails because of a full disk or an exceeded disk quota, it prints a message to the error log every 10 minutes, and waits until disk space becomes available. (Bug #3248 [<http://bugs.mysql.com/3248>])
- Now MySQL does not prefer columns, which are mentioned in select list but are renamed, over columns from other tables participating in FROM clause when it resolves GROUP BY clause (e.g. SELECT t1.a AS c FROM t1, t2 ORDER BY a produces an error if both t1 and t2 tables contain a column). (Bug #4302 [<http://bugs.mysql.com/4302>])
- Behavior of ALTER TABLE converting column containing NULL values to AUTO_INCREMENT column is no longer affected by NO_AUTO_VALUE_ON_ZERO mode. (Bug #5915 [<http://bugs.mysql.com/5915>]).

D.2.9. Changes in release 4.1.5 (16 Sep 2004)

Functionality added or changed:

- InnoDB: Added configuration option `innodb_autoextend_increment` for setting the size in megabytes by which InnoDB tablespaces are extended when they become full. The default value is 8, corresponding to the fixed increment of 8MB in previous versions of MySQL.
- InnoDB: The new Windows installation wizard of MySQL makes InnoDB as the MySQL default table type on Windows, unless explicitly specified otherwise. Note that it places the `my.ini` file in the installation directory of the MySQL server. See Section 2.3.5.14, “The Location of the `my.ini` File”.

Bugs fixed:

- Fixed a bug which caused the server to crash on attempt to execute a prepared statement with `BETWEEN ? AND ?` and a datetime column. (Bug #5748 [<http://bugs.mysql.com/5748>])
- Fixed name resolving of external fields of subqueries if subquery placed in select list of query with grouping. (Bug #5326 [<http://bugs.mysql.com/5326>])
- Fixed detection of using same table for updating and selecting in multi-update queries. (Bug #5455 [<http://bugs.mysql.com/5455>])
- The values of the `max_sort_length`, `sql_mode`, and `group_concat_max_len` system variables now are stored in the query cache with other query information to avoid returning an incorrect result from the query cache. (Bug #5394 [<http://bugs.mysql.com/5394>]) (Bug #5515 [<http://bugs.mysql.com/5515>])
- Fixed syntax analyzer with `sql_mode=IGNORE_SPACE`. It happened to take phrases like `default .07` as `identifier.identifier`. (Bug #5318 [<http://bugs.mysql.com/5318>])

- Fixed illegal internal field length of user variables of integer type. This showed up when creating a table as `SELECT @var_name`. (Bug #4788 [<http://bugs.mysql.com/4788>])
- Fixed a buffer overflow in prepared statements API (libmysqlclient) when a statement containing thousands of placeholders was executed. (Bug #5194 [<http://bugs.mysql.com/5194>])
- Fixed a bug in the server when after reaching a certain limit of prepared statements per connection (97), statement ids began to overlap, so occasionally wrong statements were chosen for execution. (Bug #5399 [<http://bugs.mysql.com/5399>])
- Fixed a bug in prepared statements when `LIKE` used with arguments in different character sets crashed server on first execute. (Bug #4368 [<http://bugs.mysql.com/4368>])
- Fixed a bug in prepared statements when providing '0000-00-00' date to a parameter lead to server crash. (Bug #4231 [<http://bugs.mysql.com/4231>], Bug #4562 [<http://bugs.mysql.com/4562>])
- Fixed a bug in `OPTIMIZE TABLE` that could cause table corruption on `FULLTEXT` indexes. (Bug #5327 [<http://bugs.mysql.com/5327>])
- InnoDB: Fixed a bug that InnoDB only allowed a maximum of 1000 connections inside InnoDB at the same time. A higher number could cause an assertion failure in `sync0arr.c`, line 384. Now we allow 1000, 10000, or 50000, depending on the buffer pool size. (Bug #5414 [<http://bugs.mysql.com/5414>])

D.2.10. Changes in release 4.1.4 (26 Aug 2004: Gamma)

Note: To fix a compile problem on systems that do not have automake 1.7 installed, an updated 4.1.4a source tarball has been published. In addition to resolving this automake dependency (Bug #5319), it also fixes some reported libedit compile errors when using a non-gcc compiler (Bug #5353 [<http://bugs.mysql.com/5353>]).

Functionality added or changed:

- Added the CSV storage engine.
- Made internal representation of `TIMESTAMP` values in InnoDB in 4.1 to be the same as in 4.0. This difference resulted in incorrect datetime values in `TIMESTAMP` columns in InnoDB tables after an upgrade from 4.0 to 4.1. (Bug #4492 [<http://bugs.mysql.com/4492>]) **Warning: extra steps during upgrade required!** Unfortunately this means that if you are upgrading from 4.1.x, where $x \leq 3$, to 4.1.4 you should use `mysqldump` for saving and then restoring your InnoDB tables with `TIMESTAMP` columns.
- The `mysqld-opt` Windows server was renamed to `mysqld`. This completes the Windows server renaming begun in MySQL 4.1.2. See Section 2.3.9, “Selecting a MySQL Server type”.
- Added Latin language collations for the `ucs2` and `utf8` Unicode character sets. These are called `ucs2_roman_ci` and `utf8_roman_ci`.
- Corrected the name of the Mac OS X StartupItem script (it must match the name of the subdirectory, which was renamed to `MySQLCOM` in MySQL 4.1.2). Thanks to Bryan McCormack for reporting this.
- Added `--start-datetime`, `--stop-datetime`, `--start-position`, and `--stop-position` options to `mysqlbinlog`. These make point-in-time recovery easier.
- Killing a `CHECK TABLE` statement does not result in the table being marked as “corrupted” any more; the table remains as if `CHECK TABLE` had not even started. See Section 13.5.5.3, “KILL Syntax”.

- Made the MySQL server ignore SIGHUP and SIGQUIT on Mac OS X 10.3. This is needed because under this OS, the MySQL server receives lots of these signals (reported as Bug #2030 [<http://bugs.mysql.com/2030>]).
- Support of usage of column aliases qualified by table name or alias in ORDER BY and GROUP BY was dropped. For example the following query `SELECT a AS b FROM t1 ORDER BY t1.b` is not allowed. One should use `SELECT a AS b FROM t1 ORDER BY t1.a` or `SELECT a AS b FROM t1 ORDER BY b` instead. This was non-standard (since aliases are defined on query level not on table level) and caused problems with some queries.

Bugs fixed:

- Fixed a bug that caused libmysql to crash when attempting to fetch a value of MEDIUMINT column. (Bug #5126 [<http://bugs.mysql.com/5126>])
- Fixed a bug that caused the MySQL server to crash when attempting to execute a prepared statement with `SELECT ... INTO @var` for a second time. (Bug #5034 [<http://bugs.mysql.com/5034>])
- Fixed execution of optimized IN subqueries that use compound indexes. (Bug #4435 [<http://bugs.mysql.com/4435>])
- Prohibited resolving of table fields in inner queries if fields do not take part in grouping for queries with grouping (inside aggregate function arguments, all table fields are still allowed). (Bug #4814 [<http://bugs.mysql.com/4814>])
- Fixed a crash after SLAVE STOP if the IO thread was in a special state. (Bug #4629 [<http://bugs.mysql.com/4629>])
- Fixed an old bug in concurrent accesses to MERGE tables (even one MERGE table and MyISAM tables), that could have resulted in a crash or hang of the server. (Bug #2408 [<http://bugs.mysql.com/2408>], CAN-2004-0837 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0837>])
- Fixed a bug that caused server crash on attempt to execute for a second time a prepared statement with NOT in WHERE or ON clauses. (Bug #4912 [<http://bugs.mysql.com/4912>])
- MATCH ... AGAINST now works in a subquery. (Bug #4769 [<http://bugs.mysql.com/4769>])
- Fixed a bug that omitted the .err extension of the error log file (`--log-error`) when the hostname contained a domain name. The domain name is now replaced by the extension. (Bug #4997 [<http://bugs.mysql.com/4997>])
- Fixed a crash in **myisamchk**. (Bug #4901 [<http://bugs.mysql.com/4901>])
- Fixed a bug which caused server crash if one used the CONVERT_TZ () function with time zone described in database as parameter and this time zone was not used before. (Bug #4508 [<http://bugs.mysql.com/4508>])
- Support for %T, %r, %V, %v and %X, %x format specifiers was added to STR_TO_DATE () function. (Bug #4756 [<http://bugs.mysql.com/4756>])
- Fixed a bug (hang) in NATURAL JOIN where joined table had no common column. (Bug #4807 [<http://bugs.mysql.com/4807>])
- Fixed a crash caused by UNHEX (NULL). (Bug #4441 [<http://bugs.mysql.com/4441>])
- **mysql_fix_privilege_tables** didn't correctly handle the argument of its `--password=#` option. (Bug #4240 [<http://bugs.mysql.com/4240>], Bug #4543 [<http://bugs.mysql.com/4543>])
- Fixed that **mysqlbinlog --read-from-remote-server** sometimes couldn't accept 2 binary logs on command line. (Bug #4507 [<http://bugs.mysql.com/4507>])

- Fixed that **mysqlbinlog --position --read-from-remote-server** had wrong # at lines. (Bug #4506 [<http://bugs.mysql.com/4506>])
- If `CREATE TEMPORARY TABLE t SELECT` failed while loading the data, the temporary table was not dropped. (Bug #4551 [<http://bugs.mysql.com/4551>])
- Fixed that when a multiple-table `DROP TABLE` failed to drop a table on the master server, the error code was not written to the binary log. (Bug #4553 [<http://bugs.mysql.com/4553>])
- When the slave SQL thread was replicating a `LOAD DATA INFILE` statement, it didn't show the statement in the output of `SHOW PROCESSLIST`. (Bug #4326 [<http://bugs.mysql.com/4326>])
- Fixed an assertion failure when reading the grant tables (Bug #4407 [<http://bugs.mysql.com/4407>])
- Fixed that `CREATE TABLE ... TYPE=HEAP ... AS SELECT...` caused replication slave to stop. (Bug #4971 [<http://bugs.mysql.com/4971>])
- Fixed that `mysql_options(..., MYSQL_OPT_LOCAL_INFILE, ...)` failed to disable `LOAD DATA LOCAL INFILE`. (Bug #5038 [<http://bugs.mysql.com/5038>])
- Fixed that `disable-local-infile` option had no effect if client read it from a configuration file using `mysql_options(..., MYSQL_READ_DEFAULT, ...)`. (Bug #5073 [<http://bugs.mysql.com/5073>])
- Fixed that `SET GLOBAL SYNC_BINLOG` did not work on some platforms (Mac OS X). (Bug #5064 [<http://bugs.mysql.com/5064>])
- Fixed that **mysql-test-run** failed on the `rpl_trunc_binlog` test if running test from the installed (the target of 'make install') directory. (Bug #5050 [<http://bugs.mysql.com/5050>])
- Fixed that **mysql-test-run** failed on the `grant_cache` test when run as Unix user 'root'. (Bug #4678 [<http://bugs.mysql.com/4678>])
- Fixed an unlikely deadlock which could happen when using `KILL`. (Bug #4810 [<http://bugs.mysql.com/4810>])
- Fixed a crash when one connection got KILLED while it was doing `START SLAVE`. (Bug #4827 [<http://bugs.mysql.com/4827>])
- Made `FLUSH TABLES WITH READ LOCK` block `COMMIT` if server is running with binary logging; this ensures that the binary log position is trustable when doing a full backup of tables and the binary log. (Bug #4953 [<http://bugs.mysql.com/4953>])
- Fixed that the counter of an `auto_increment` column was not reset by `TRUNCATE TABLE` if the table was a temporary table. (Bug #5033 [<http://bugs.mysql.com/5033>])
- Fixed bug which caused error to be reported when column from `ORDER BY` clause was present in two tables participating in `SELECT` even if the second instance of column in select list was renamed. (Bug #4302 [<http://bugs.mysql.com/4302>])

D.2.11. Changes in release 4.1.3 (28 Jun 2004: Beta)

Note: The initial release of MySQL 4.1.3 for Windows accidentally was not compiled with support for the Spatial Extensions (OpenGIS). This was fixed by rebuilding from the same 4.1 code snapshot with the missing option and releasing those packages as version 4.1.3a.

To enable compiling the newly released PHP 5 against MySQL 4.1.3 on Windows, the Windows packages had to be rebuilt once more to add a few missing symbols to the MySQL client library. These packages were released as MySQL 4.1.3b.

Functionality added or changed:

- Added the ARCHIVE storage engine.
- Added SQL syntax for prepared statements. See Section 13.7, “SQL Syntax for Prepared Statements”.
- Language-specific collations were added for the `ucs2` and `utf8` Unicode character sets: Icelandic, Latvian, Romanian, Slovenian, Polish, Estonian, Swedish, Turkish, Czech, Danish, Lithuanian, Slovak, Spanish, Traditional Spanish.
- Support for per-connection time zones was added. Now you can set the current time zone for a connection by setting the `@@time_zone` system variable to a value such as `'+10:00'` or `'Europe/Moscow'` (where `'Europe/Moscow'` is the name of one of the time zones described in the system tables). Functions like `CURRENT_TIMESTAMP`, `UNIX_TIMESTAMP`, and so forth honor this time zone. Values of `TIMESTAMP` type are also interpreted as values in this time zone. So now our `TIMESTAMP` type behaves similar to Oracle's `TIMESTAMP WITH LOCAL TIME ZONE`. That is, values stored in such a column are normalized toward UTC and converted back to the current connection time zone when they are retrieved from such a column. To set up the tables that store time zone information, see Section 2.9, “Post-Installation Setup and Testing”.
- **Warning: Incompatible change!** The `timezone` system variable has been removed and replaced by `system_time_zone`. See Section 5.3.3, “Server System Variables”.
- Basic time zone conversion function `CONVERT_TZ()` was added. It assumes that its first argument is a datetime value in the time zone specified by its second argument and returns the equivalent datetime value in the time zone specified by its third argument.
- `CHECK TABLE` now can be killed. It then marks the table as corrupted. See Section 13.5.5.3, “KILL Syntax”.
- **Warning: Incompatible change!** C API change: `mysql_shutdown()` now requires a second argument. This is a source-level incompatibility that affects how you compile client programs; it does not affect the ability of compiled clients to communicate with older servers. See Section 24.2.3.54, “`mysql_shutdown()`”.
- `OPTIMIZE TABLE` for InnoDB tables is now mapped to `ALTER TABLE` instead of `ANALYZE TABLE`.
- `sync_frm` is now a settable global variable (not only a startup option).
- Added the `sync_binlog=N` global variable and startup option, which makes the MySQL server synchronize its binary log to disk (`fdatasync()`) after every Nth write to the binary log.
- Changed the slave SQL thread to print fewer useless error messages (no more message duplication; no more messages when an error is skipped (because of `slave-skip-errors`)).
- `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, single-table `DELETE` and single-table `UPDATE` are now written to the binary log even if they changed nothing on the master (for example, even if the `DELETE` matched no row). The old behavior sometimes caused bad surprises in replication setups.
- Replication and **mysqlbinlog** now have better support for the case that the session character set and collation variables are changed within a given session. See Section 6.7, “Replication Features and Known Problems”.
- Added `--innodb-safe-binlog` server option, which adds consistency guarantees between the content of InnoDB tables and the binary log. See Section 5.10.4, “The Binary Log”.
- `LIKE` now supports the use of a prepared statement parameter or delimited constant expression

as the argument to `ESCAPE` (Bug #4200 [<http://bugs.mysql.com/4200>]).

Bugs fixed:

- Fixed `CREATE DATABASE IF NOT EXISTS` for Win32 which caused an error if database existed. (Bug #4378 [<http://bugs.mysql.com/4378>])
- Added missing `root` account to Windows version of **mysqld**. (Bug #4242 [<http://bugs.mysql.com/4242>])
- Fixed bug in prepared `EXPLAIN` statement which led to server crash. (Bug #4271 [<http://bugs.mysql.com/4271>])
- Fixed a bug of using parameters in some prepared statements via SQL syntax. (Bug #4280 [<http://bugs.mysql.com/4280>])
- Fixed a bug in `MERGE` tables created with `INSERT_METHOD=LAST`, that were not able to report a key number that caused "Duplicate entry" error for `UNIQUE` key in `INSERT`. As a result, error message was not precise enough (error 1022 instead of error 1062) and `INSERT ... ON DUPLICATE KEY UPDATE` did not work. (Bug #4008 [<http://bugs.mysql.com/4008>])
- Fixed a bug in `DELETE` from a table with `FULLTEXT` indexes which under rare circumstances could result in a corrupted table, if words of different lengths may be considered equal (which is possible in some collations, for example, in `utf8_general_ci` or `latin1_german2_ci`). (Bug #3808 [<http://bugs.mysql.com/3808>])
- Fixed too-early unlocking of tables if we have subquery in `HAVING` clause. (Bug #3984 [<http://bugs.mysql.com/3984>])
- Fixed a bug in **mysqldump** when it didn't return an error if the output device was filled (Bug #1851 [<http://bugs.mysql.com/1851>])
- Fixed a bug in client-side conversion of string column to `MYSQL_TIME` application buffer (prepared statements API). (Bug #4030 [<http://bugs.mysql.com/4030>])
- Fixed a bug with server crash on attempt to execute a non-prepared statement. (Bug #4236 [<http://bugs.mysql.com/4236>])
- Fixed a bug with server crash on attempt to prepare a statement with character set introducer. (Bug #4105 [<http://bugs.mysql.com/4105>])
- Fixed bug which caused different number of warnings to be generated when bad datetime as string or as number was inserted into `DATETIME` or `TIMESTAMP` column. (Bug #2336 [<http://bugs.mysql.com/2336>])
- Fixed some byte order bugs with prepared statements on machines with high-byte-first. (Bug #4173 [<http://bugs.mysql.com/4173>])
- Fixed unlikely bug in the range optimizer when using many `IN()` queries on different key parts. (Bug #4157 [<http://bugs.mysql.com/4157>])
- Fixed problem with `NULL` and derived tables. (Bug #4097 [<http://bugs.mysql.com/4097>])
- Fixed wrong `UNION` results if display length of fields for numeric types was set less than real length of values in them. (Bug #4067 [<http://bugs.mysql.com/4067>])
- Fixed a bug in `mysql_stmt_close()`, which hung up when attempting to close statement after failed `mysql_stmt_fetch()`. (Bug #4079 [<http://bugs.mysql.com/4079>])
- Fixed bug of re-execution optimized `COUNT(*)`, `MAX()` and `MIN()` functions in prepared statements. (Bug #2687 [<http://bugs.mysql.com/2687>])

- Fixed a bug with `COUNT(DISTINCT)` performance degradation in cases like `COUNT(DISTINCT a TEXT, b CHAR(1))` (no index used). (Bug #3904 [<http://bugs.mysql.com/3904>])
- Fixed a bug in `MATCH ... AGAINST(... IN BOOLEAN MODE)` that under rare circumstances could cause wrong results if in the data's collation one byte could match many (like in `utf8_general_ci` or `latin1_german2_ci`). (Bug #3964 [<http://bugs.mysql.com/3964>])
- Fixed a bug in prepared statements protocol, when microseconds part of `MYSQL_TYPE_TIME/MYSQL_TYPE_DATETIME` columns was not sent to the client. (Bug #4026 [<http://bugs.mysql.com/4026>])
- Fixed a bug that using `--with-charset` with **configure** didn't affect the MySQL client library. (Bug #3990 [<http://bugs.mysql.com/3990>])
- Fixed a bug in authentication code that allowed a malicious user to bypass password verification with specially crafted packets, using a modified client library. (CAN-2004-0627 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0627>], CAN-2004-0628 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0628>])
- Fixed bug with wrong result of `CONCAT(?, col_name)` in prepared statements. (Bug #3796 [<http://bugs.mysql.com/3796>])
- Fixed potential memory overrun in `mysql_real_connect()` (which required a compromised DNS server and certain operating systems). (Bug #4017 [<http://bugs.mysql.com/4017>], CAN-2004-0836 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0836>])
- During the installation process of the server RPM on Linux, **mysqld** was run as the `root` system user, and if you had `--log-bin=file_name`, where the file was located somewhere outside of the data directory, it created binary log files owned by `root` in this directory that remained owned by `root` after the installation. This is now fixed by starting **mysqld** as the `mysql` system user instead. (Bug #4038 [<http://bugs.mysql.com/4038>])
- Made `DROP DATABASE` honor the value of `lower_case_table_names`. (Bug #4066 [<http://bugs.mysql.com/4066>])
- The slave SQL thread refused to replicate `INSERT ... SELECT` if it examined more than 4 billion rows. (Bug #3871 [<http://bugs.mysql.com/3871>])
- **mysqlbinlog** didn't escape the string content of user variables, and did not deal well when these variables were in non-ASCII character sets; this is now fixed by always printing the string content of user variables in hexadecimal. The character set and collation of the string is now also printed. (Bug #3875 [<http://bugs.mysql.com/3875>])
- Fixed incorrect destruction of expression which led to crash of server on complex AND/OR expressions if query was ignored (either by a replication server because of `--replicate-*-table` rules, or by any MySQL server because of a syntax error). (Bug #3969 [<http://bugs.mysql.com/3969>], Bug #4494 [<http://bugs.mysql.com/4494>])

D.2.12. Changes in release 4.1.2 (28 May 2004)

Functionality added or changed:

- Added the `EXAMPLE` storage engine.
- The **mysqld** Windows server was renamed to **mysqld-debug**. See Section 2.3.9, “Selecting a MySQL Server type”.
- Added `Handler_discover` status variable.
- Added support for character set conversion and `MYSQL_TYPE_BLOB` type code in prepared

statement protocol.

- Added explanation of hidden SELECT of UNION in output of EXPLAIN SELECT statement.
- **mysql** command-line client now supports multiple `-e` options. (Bug #591 [http://bugs.mysql.com/591])
- New `myisam_data_pointer_size` system variable. See Section 5.3.3, “Server System Variables”.
- The `--log-warnings` server option now is enabled by default. Disable with `--skip-log-warnings`.
- The `--defaults-file=file_name` option now requires that the filename must exist (safety fix). (Bug #3413 [http://bugs.mysql.com/3413])
- **mysqld_multi** now creates the log in the directory named by `datadir` (from the `[mysqld]` section in `my.cnf` or compiled in), not in `/tmp`. Thanks to Christian Hammers from Debian Security Team for reporting this. (CAN-2004-0388 [http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0388])
- **Warning: Incompatible change!** String comparison now works according to the SQL standard. Because we have that `'a' = 'a '` then from it must follow that `'a' > 'a\t'`. (The latter was not the case before MySQL 4.1.2.) To implement it, we had to change how storage engines compare strings internally. As a side effect, if you have a table where a CHAR or VARCHAR column in some row has a value with the last character less than ASCII(32), you have to repair this table. CHECK TABLES tells you if this problem exists. (Bug #3152 [http://bugs.mysql.com/3152])
- Added support for DEFAULT CURRENT_TIMESTAMP and for ON UPDATE CURRENT_TIMESTAMP specifications for TIMESTAMP columns. Now you can explicitly say that a TIMESTAMP column should be set automatically to the current timestamp for INSERT and/or UPDATE statements, or even prevent the column from updating automatically. Only one column with such an auto-set feature per table is supported. TIMESTAMP columns created with earlier versions of MySQL behave as before. Behavior of TIMESTAMP columns that were created without explicit specification of default/on as earlier depends on its position in table: If it is the first TIMESTAMP column, it be treated as having been specified as TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP. In other cases, it would be treated as a TIMESTAMP DEFAULT 0 column. NOW is supported as an alias for CURRENT_TIMESTAMP. **Warning: Incompatible change!** Unlike in previous versions, explicit specification of default values for TIMESTAMP column is never ignored and turns off the auto-set feature (unless you have CURRENT_TIMESTAMP as the default).
- **Warning: Incompatible change!** Renamed prepared statements C API functions:

Old Name	New Name
<code>mysql_bind_param()</code>	<code>mysql_stmt_bind_param()</code>
<code>mysql_bind_result()</code>	<code>mysql_stmt_bind_result()</code>
<code>mysql_prepare()</code>	<code>mysql_stmt_prepare()</code>
<code>mysql_execute()</code>	<code>mysql_stmt_execute()</code>
<code>mysql_fetch()</code>	<code>mysql_stmt_fetch()</code>
<code>mysql_fetch_column()</code>	<code>mysql_stmt_fetch_column()</code>
<code>mysql_param_count()</code>	<code>mysql_stmt_param_count()</code>
<code>mysql_param_result()</code>	<code>mysql_stmt_param_metadata()</code>

<code>mysql_get_metadata()</code>	<code>mysql_stmt_result_metadata()</code>
<code>mysql_send_long_data()</code>	<code>mysql_stmt_send_long_data()</code>

Now all functions that operate with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

- **Warning: Incompatible change!** The signature of the `mysql_stmt_prepare()` function was changed to `int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *query, unsigned long length)`. To create a `MYSQL_STMT` handle, you should use the `mysql_stmt_init()` function, not `mysql_stmt_prepare()`.
- `SHOW GRANTS` with no `FOR` clause or with `FOR CURRENT_USER()` shows the privileges for the current session.
- The improved character set support introduced in MySQL 4.1.0 for the `MyISAM` and `HEAP` storage engines is now available for `InnoDB` as well.
- A name of ```Primary`" no longer can be specified as an index name. (That name is reserved for the `PRIMARY KEY` if the table has one.) (Bug #856 [<http://bugs.mysql.com/856>])
- MySQL now issues a warning when a `SET` or `ENUM` column with duplicate values in the list is created. (Bug #1427 [<http://bugs.mysql.com/1427>])
- Now `SQL_SELECT_LIMIT` variable has no influence on subqueries. (Bug #2600 [<http://bugs.mysql.com/2600>])
- `UNHEX()` function implemented. See Section 12.3, "String Functions".
- The **mysql** command-line client no longer stores in the history file multiple copies of identical queries that are run consecutively.
- Multi-line statements in the `mysql` command-line client now are stored in the history file as a single line.
- `UUID()` function implemented. Note that it does not work with replication yet. See Section 12.8.4, "Miscellaneous Functions".
- Prepared statements with all types of subqueries fixed.
- MySQL now supports up to 64 indexes per table.
- `MyISAM` tables now support keys up to 1000 bytes long.
- `MyISAM` and `InnoDB` tables now support index prefix lengths up to 1000 bytes long.
- If you try to create a key with a key part that is too long, and it is safe to auto-truncate it to a smaller length, MySQL now does so. A warning is generated, rather than an error.
- The `ft_boolean_syntax` variable now can be changed while the server is running. See Section 5.3.3, "Server System Variables".
- `REVOKE ALL PRIVILEGES, GRANT FROM user_list` is changed to a more consistent `REVOKE ALL PRIVILEGES, GRANT OPTION FROM user_list`. (Bug #2642 [<http://bugs.mysql.com/2642>])
- Internal string-to-number conversion now supports only `SQL:2003` compatible syntax for numbers. In particular, `'0x10'+0` does not work anymore. (Actually, it worked only on some systems before, such as Linux. It did not work on others, such as FreeBSD or Solaris. Making these queries OS-independent was the goal of this change.) Use `CONV()` to convert hexadecimal

numbers to decimal. E.g. `CONV(MID('0x10',3),16,10)+0`.

- **mysqlhotcopy** now works on NetWare.
- `ALTER TABLE DROP PRIMARY KEY` no longer drops the first `UNIQUE` index if there is no primary index. (Bug #2361 [<http://bugs.mysql.com/2361>])
- Added `latin1_spanish_ci` (Modern Spanish) collation for the `latin1` character set.
- Added the `ENGINE` table option as a synonym for the `TYPE` option for `CREATE TABLE` and `ALTER TABLE`.
- Added the `--default-storage-engine` server option as a synonym for `--default-table-type`.
- Added the `storage_engine` system variable as a synonym for `table_type`.
- **Warning: Incompatible change!** The `Type` output column for `SHOW TABLE STATUS` now is labeled `Engine`.
- Added `init_connect` and `init_slave` system variables. The values should be SQL statements to be executed when each client connects or each time a slave's SQL thread starts, respectively.
- C API enhancement: `SERVER_QUERY_NO_INDEX_USED` and `SERVER_QUERY_NO_GOOD_INDEX_USED` flags are now set in the `server_status` field of the `MYSQL` structure. It is these flags that make the query to be logged as slow if **mysqld** was started with `--log-slow-queries --log-queries-not-using-indexes`.
- For replication of `MEMORY` (HEAP) tables: Made the master automatically write a `DELETE FROM` statement to its binary log when a `MEMORY` table is opened for the first time since master's startup. This is for the case where the slave has replicated a non-empty `MEMORY` table, then the master is shut down and restarted: the table is now empty on master; the `DELETE FROM` empties it on slave too. Note that even with this fix, between the master's restart and the first use of the table on master, the slave still has out-of-date data in the table. But if you use the `init-file` option to populate the `MEMORY` table on the master at startup, it ensures that the failing time interval is zero. (Bug #2477 [<http://bugs.mysql.com/2477>])
- When a session having open temporary tables terminates, the statement automatically written to the binary log is now `DROP TEMPORARY TABLE IF EXISTS` instead of `DROP TEMPORARY TABLE`, for more robustness.
- The MySQL server now returns an error if `SET SQL_LOG_BIN` or `SET SQL_LOG_UPDATE` is issued by a user without the `SUPER` privilege (in previous versions it just silently ignored the statement in this case).
- Changed that when the MySQL server has binary logging disabled (that is, no `--log-bin` option was used), then no transaction binary log cache is allocated for connections. This should save `binlog_cache_size` bytes of memory (32KB by default) for every connection.
- Added `Binlog_cache_use` and `Binlog_cache_disk_use` status variables that count the number of transactions that used transaction binary log and that had to flush this temporary binary log to disk instead of using only the in-memory buffer. They can be used for tuning the `binlog_cache_size` system variable.
- Added option `--replicate-same-server-id`.
- The Mac OS X Startup Item has been moved from the directory `/Library/StartupItems/MySQL` to `/Library/StartupItems/MySQLCOM` to avoid a file name collision with the MySQL Startup Item installed with Mac OS X Server. See Section 2.12.2, "Mac OS X Notes".
- Added option `--to-last-log` to **mysqlbinlog**, for use in conjunction with -

`-read-from-remote-server.`

Bugs fixed:

- Fixed check of EXPLAIN of UNION. (Bug #3639 [<http://bugs.mysql.com/3639>])
- Fixed a bug in a query that used DISTINCT and ORDER BY by column's real name, while the column had an alias, specified in SELECT clause. (Bug #3681 [<http://bugs.mysql.com/3681>])
- **mysqld** could crash when a table was altered and used at the same time. This was a 4.1.2-specific bug. (Bug #3643 [<http://bugs.mysql.com/3643>]).
- Fixed bug when using impossible WHERE with PROCEDURE ANALYSE(). (Bug #2238 [<http://bugs.mysql.com/2238>]).
- Fixed security problem in new authentication where password was not checked for changed GRANT accounts until FLUSH PRIVILEGES was executed. (Bug #3404 [<http://bugs.mysql.com/3404>])
- Fixed crash of GROUP_CONCAT() on expression with ORDER BY and external ORDER BY in a query. (Bug #3752 [<http://bugs.mysql.com/3752>])
- Fixed a bug in ALL/SOME subqueries in case of optimization (key field present in subquery). (Bug #3646 [<http://bugs.mysql.com/3646>])
- Fixed a bug in SHOW GRANTS and EXPLAIN SELECT character set conversion. (Bug #3403 [<http://bugs.mysql.com/3403>])
- Prepare statements parameter do not cause error message as fields used in select list but not included in ORDER BY list.
- UNION statements did not consult SQL_SELECT_LIMIT value when set. This is now fixed properly, which means that this limit is applied to the top level query, unless LIMIT for entire UNION is used.
- Fixed a bug in multiple-table UPDATE statements that resulted in an error when one of the tables was not updated but was used in the nested query, contained therein.
- Fixed mysql_stmt_send_long_data() behavior on second execution of prepared statement and in case when long data had zero length. (Bug #1664 [<http://bugs.mysql.com/1664>])
- Fixed crash on second execution of prepared statement with UNION. (Bug #3577 [<http://bugs.mysql.com/3577>])
- Fixed incorrect results of aggregate functions in subquery with empty result set. (Bug #3505 [<http://bugs.mysql.com/3505>])
- You can now call mysql_stmt_attr_set(..., STMT_ATTR_UPDATE_MAX_LENGTH) to tell the client library to update MYSQL_FIELD->max_length when doing mysql_stmt_store_result(). (Bug #1647 [<http://bugs.mysql.com/1647>]).
- Added support for unsigned integer types to prepared statement API (Bug #3035 [<http://bugs.mysql.com/3035>]).
- Fixed crash in prepared statements when subquery in the FROM clause with parameter used. (Bug #3020 [<http://bugs.mysql.com/3020>])
- Fixed unknown error when negative value bind to unsigned. (Bug #3223 [<http://bugs.mysql.com/3223>])
- Fixed aggregate function in prepared statements. (Bug #3360 [<http://bugs.mysql.com/3360>])

- Incorrect error message when wrong table used in multiple-table DELETE statement in prepared statements. (Bug #3411 [<http://bugs.mysql.com/3411>])
- Requiring UPDATE privilege for tables which are not updated in multiple-table UPDATE statement in prepared statements.
- Fixed prepared statement support for INSERT, REPLACE, CREATE, DELETE, SELECT, DO, SET and SHOW. All other commands are prohibited via prepared statement interface. (Bug #3398 [<http://bugs.mysql.com/3398>], Bug #3406 [<http://bugs.mysql.com/3406>], Bug #2811 [<http://bugs.mysql.com/2811>])
- Fixed a lot of bugs in GROUP_CONCAT(). (Bug #2695 [<http://bugs.mysql.com/2695>], Bug #3381 [<http://bugs.mysql.com/3381>], Bug #3319 [<http://bugs.mysql.com/3319>])
- Added optimization that allows for prepared statements using a large number of tables or tables with a large number of columns to be re-executed significantly faster. (Bug #2050 [<http://bugs.mysql.com/2050>])
- Fixed bug that caused execution of prepared statements to fail then table that this statement were using left table cache. This bug showed up as if this prepared statement used random garbage as column names or as server crashes. (Bug #3307 [<http://bugs.mysql.com/3307>])
- Fixed a problem resulting from setting the character_set_results variable to NULL. (Bug #3296 [<http://bugs.mysql.com/3296>])
- Fixed query cache statistics.
- Fixed bug in ANALYZE TABLE on a BDB table inside a transaction that hangs server thread. (Bug #2342 [<http://bugs.mysql.com/2342>])
- Fixed a symlink vulnerability in the mysqlbug script. (Bug #3284 [<http://bugs.mysql.com/3284>], CAN-2004-0381 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0381>])
- Fixed a bug in parallel repair (**myisamchk -p**, `myisam_repair_threads`); sometimes the repair process failed to repair a table. (Bug #1334 [<http://bugs.mysql.com/1334>])
- A query that uses both UNION [DISTINCT] and UNION ALL now works correctly. (Bug #1428 [<http://bugs.mysql.com/1428>])
- Table default character set affects LONGBLOB columns. (Bug #2821 [<http://bugs.mysql.com/2821>])
- CONCAT_WS() makes the server die in case of illegal mix of collations. (Bug #3087 [<http://bugs.mysql.com/3087>])
- UTF8 charset breaks joins with mixed column/string constant. (Bug #2959 [<http://bugs.mysql.com/2959>])
- Fixed DROP DATABASE to report number of tables deleted.
- Fixed bug in privilege checking of ALTER TABLE RENAME. (Bug #3270 [<http://bugs.mysql.com/3270>], CAN-2004-0835 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0835>])
- Fixed memory leak in the client library when statement handle was freed on closed connection (call to `mysql_stmt_close` after `mysql_close`). (Bug #3073 [<http://bugs.mysql.com/3073>])
- Fixed server segfaults when processing malformed prepared statements commands. (Bug #2795 [<http://bugs.mysql.com/2795>], Bug #2274 [<http://bugs.mysql.com/2274>])
- Fixed using subqueries with OR and AND functions. (Bug #2838 [<http://bugs.mysql.com/2838>])

- Fixed comparison of tables/database names with `--lower_case_table_names` option. (Bug #2880 [<http://bugs.mysql.com/2880>])
- Removed try to check NULL if index built on column where NULL is impossible in IN subquery optimization. (Bug #2393 [<http://bugs.mysql.com/2393>])
- Fixed incorrect parsing of subqueries in the FROM clause. (Bug #2421 [<http://bugs.mysql.com/2421>])
- Fixed processing of `RAND()` in subqueries with static tables. (bug #2645 [<http://bugs.mysql.com/2645>])
- Fixed bug with quoting of table names in **mysqldump** for various values of `sql_mode` of server. (Bug #2591 [<http://bugs.mysql.com/2591>])
- Fixed bug with storing values that are out of range for DOUBLE and FLOAT columns. (Bug #2082 [<http://bugs.mysql.com/2082>])
- Fixed bug with compiling `--with-pstack` with binutils 2.13.90. (Bug #1661 [<http://bugs.mysql.com/1661>])
- Fixed a bug in the GRANT system. When a password was assigned to an account at the global level and then privileges were granted at the database level (without specifying any password), the existing password was replaced temporarily in memory until the next `FLUSH PRIVILEGES` operation or the server was restarted. (Bug #2953 [<http://bugs.mysql.com/2953>])
- Fixed a bug in full-text search on multi-byte character set (such as UTF8) that appeared when a search word was shorter than a matching word from the index (for example, searching for "Uppsala" when table data contain "Uppsa*la"). (Bug #3011 [<http://bugs.mysql.com/3011>])
- Fixed a bug that made `Max_used_connections` to be less than the actual maximum number of connections in use simultaneously.
- Fixed calculation of `Index_length` in HEAP table status for BTREE indexes. (Bug #2719 [<http://bugs.mysql.com/2719>])
- Fixed `mysql_stmt_affected_rows()` call to always return number of rows affected by given statement. (Bug #2247 [<http://bugs.mysql.com/2247>])
- Fixed crash in `MATCH . . . AGAINST()` on a phrase search operator with a missing closing double quote. (Bug #2708 [<http://bugs.mysql.com/2708>])
- Fixed output of **mysqldump --tab**. (Bug #2705 [<http://bugs.mysql.com/2705>])
- Fix for a bug in UNION operations that prevented proper handling of NULL columns. This happened only if a column in the first SELECT node was NOT NULL. (Bug #2508 [<http://bugs.mysql.com/2508>])
- Fix for a bug in UNION operations with InnoDB storage engine, when some columns from one table were used in one SELECT statement and some were used in another SELECT statement. (Bug #2552 [<http://bugs.mysql.com/2552>])
- Fixed a few years old bug in the range optimizer that caused a segmentation fault on some very rare queries. (Bug #2698 [<http://bugs.mysql.com/2698>])
- Fixed bug with `SHOW CREATE TABLE . . .` which didn't properly double quotes. (Bug #2593 [<http://bugs.mysql.com/2593>])
- Queries with subqueries in FROM clause locks all tables at once for now. This also fixed bugs in EXPLAIN of subqueries in FROM output. (Bug #2120 [<http://bugs.mysql.com/2120>])
- Fixed bug with **mysqldump** not quoting "tricky" names correctly. (Bug #2592 [<http://bugs.mysql.com/2592>])

- Fix for a bug that prevented table / column privileges from being loaded on startup. (Bug #2546 [<http://bugs.mysql.com/2546>])
- Fixed bug in replication with `CREATE TABLE ... LIKE ...` that resulted in a statement not being written to the binary log. (Bug #2557 [<http://bugs.mysql.com/2557>])
- Fixed memory leak in `INSERT ... ON DUPLICATE KEY UPDATE ...` (Bug #2438 [<http://bugs.mysql.com/2438>])
- Fixed bug in the parser, making the syntax `CONVERT(expr, type)` legal again.
- Fixed parsing of short-form IP addresses in `INET_ATON()`. (Bug #2310 [<http://bugs.mysql.com/2310>])
- Fixed a bug in `CREATE ... SELECT` that sometimes caused a string column with a multi-byte character set (such as `utf8`) to have insufficient length to hold the data.
- Fixed a rare table corruption on adding data (`INSERT`, `REPLACE`, `UPDATE`, etc. but not `DELETE`) to a `FULLTEXT` index. (Bug #2417 [<http://bugs.mysql.com/2417>])
- Compile the `MySQL-client` RPM package against `libreadline` instead of `libedit`. (Bug #2289 [<http://bugs.mysql.com/2289>])
- Fix for a crashing bug that was caused by not setting `vio_timeout()` virtual function for all protocols. This bug occurred on Windows. (Bug #2025 [<http://bugs.mysql.com/2025>])
- Fix for a bug that caused `mysql` client program to erroneously cache the value of the current database. (Bug #2025 [<http://bugs.mysql.com/2025>])
- Fix for a bug that caused client/server communication to be broken when `mysql_set_server_option()` or `mysql_get_server_option()` were invoked. (Bug #2207 [<http://bugs.mysql.com/2207>])
- Fix for a bug that caused wrong results when `CAST()` was applied on `NULL` to signed or unsigned integer column. (Bug #2219 [<http://bugs.mysql.com/2219>])
- Fix for a crashing bug that occurred in the `mysql` client program when database name was longer than expected. (Bug #2221 [<http://bugs.mysql.com/2221>])
- Fixed a bug in `CHECK TABLE` that sometimes resulted in a spurious error `Found key at page ... that points to record outside datafile` for a table with a `FULLTEXT` index. (Bug #2190 [<http://bugs.mysql.com/2190>])
- Fixed bug in `GRANT` with table-level privilege handling. (Bug #2178 [<http://bugs.mysql.com/2178>])
- Fixed bug in `ORDER BY` on a small column. (Bug #2147 [<http://bugs.mysql.com/2147>])
- Fixed a bug with the `INTERVAL()` function when 8 or more comparison arguments are provided. (Bug #1561 [<http://bugs.mysql.com/1561>])
- Packaging: Fixed a bug in the Mac OS `PKG postinstall` script (`mysql_install_db` was called with an obsolete argument).
- Packaging: Added missing file `mysql_create_system_tables` to the server RPM package. This bug was fixed for the 4.1.1 RPMs by updating the `MySQL-server` RPM from `MySQL-server-4.1.1-0` to `MySQL-server-4.1.1-1`. The other RPMs were not affected by this change.
- Fixed a bug in `myisamchk` and `CHECK TABLE` that sometimes resulted in a spurious error `Found key at page ... that points to record outside datafile` for a table with a `FULLTEXT` index. (Bug #1977 [<http://bugs.mysql.com/1977>])
- Fixed a hang in full-text indexing of strings in multi-byte (all besides `utf8`) charsets. (Bug

#2065 [<http://bugs.mysql.com/2065>])

- Fixed a crash in full-text indexing of UTF8 data. (Bug #2033 [<http://bugs.mysql.com/2033>])
- Replication: a rare race condition in the slave SQL thread that could lead to an incorrect complaint that the relay log is corrupted. (Bug #2011 [<http://bugs.mysql.com/2011>])
- Replication: If a client connects to a slave server and issues an administrative statement for a table (for example, `OPTIMIZE TABLE` or `REPAIR TABLE`), this could sometimes stop the slave SQL thread. This does not lead to any corruption, but you must use `START SLAVE` to get replication going again. (Bug #1858 [<http://bugs.mysql.com/1858>])
- Replication: in the slave SQL thread, a multiple-table `UPDATE` could produce an incorrect complaint that some record was not found in one table, if the `UPDATE` was preceded by a `INSERT ... SELECT`. (Bug #1701 [<http://bugs.mysql.com/1701>])
- Replication: sometimes the master gets a non-fatal error during the execution of a statement but finally the statements succeeds (for example, a write to a MyISAM table first receives "no space left on device" but is able to finally complete, see Section A.4.3, "How MySQL Handles a Full Disk"); the bug was that the master forgot to reset the error code to 0 after success, so the error code got into its binary log, thus making the slave giving false alarms like "did not get the same error as on master". (Bug #2083 [<http://bugs.mysql.com/2083>])
- Removed a misleading "check permissions on master.info" from a replication error message, because the cause of the problem could be different from permissions. (Bug #2121 [<http://bugs.mysql.com/2121>])
- Fixed a crash when the replication slave was unable to create the first relay log. (Bug #2145 [<http://bugs.mysql.com/2145>])
- `ALTER DATABASE` caused the client to hang if the database did not exist. (Bug #2333 [<http://bugs.mysql.com/2333>])
- Multiple-table `DELETE` statements were never replicated by the slave if there were any `--replicate-*-table` options. (Bug #2527 [<http://bugs.mysql.com/2527>])
- Fixed bug in `ALTER TABLE RENAME`, when rename to the table with the same name in another database silently dropped destination table if it existed. (Bug #2628 [<http://bugs.mysql.com/2628>])
- The MySQL server did not report any error if a statement (submitted through `mysql_real_query()` or `mysql_stmt_prepare()`) was terminated by garbage characters. This can happen if you pass a wrong `length` parameter to these functions. The result was that the garbage characters were written into the binary log. (Bug #2703 [<http://bugs.mysql.com/2703>])
- Fixed bug in client library that caused `mysql_stmt_fetch` and `mysql_stmt_store_result()` to hang if they were called without prior call of `mysql_stmt_execute()`. Now they give an error instead. (Bug #2248 [<http://bugs.mysql.com/2248>])
- Made clearer the error message that one gets when an update is refused because of the `--read-only` option. (Bug #2757 [<http://bugs.mysql.com/2757>])
- Fixed that `--replicate-wild-*-table` rules apply to `ALTER DATABASE` when the table pattern is `%`, as is the case for `CREATE DATABASE` and `DROP DATABASE`. (Bug #3000 [<http://bugs.mysql.com/3000>])
- Fixed that when a `Rotate` event is found by the slave SQL thread in the middle of a transaction, the value of `Relay_Log_Pos` in `SHOW SLAVE STATUS` remains correct. (Bug #3017 [<http://bugs.mysql.com/3017>])
- Corrected the master's binary log position that InnoDB reports when it is doing a crash recovery

on a slave server. (Bug #3015 [<http://bugs.mysql.com/3015>])

- Changed the column `Seconds_Behind_Master` in `SHOW SLAVE STATUS` to never show a value of #1. (Bug #2826 [<http://bugs.mysql.com/2826>])
- Changed that when a `DROP TEMPORARY TABLE` statement is automatically written to the binary log when a session ends, the statement is recorded with an error code of value zero (this ensures that killing a `SELECT` on the master does not result in a superfluous error on the slave). (Bug #3063 [<http://bugs.mysql.com/3063>])
- Changed that when a thread handling `INSERT DELAYED` (also known as a `delayed_insert` thread) is killed, its statements are recorded with an error code of value zero (killing such a thread does not endanger replication, so we thus avoid a superfluous error on the slave). (Bug #3081 [<http://bugs.mysql.com/3081>])
- Fixed deadlock when two `START SLAVE` commands were run at the same time. (Bug #2921 [<http://bugs.mysql.com/2921>])
- Fixed that a statement never triggers a superfluous error on the slave, if it must be excluded given the `--replicate-*` options. The bug was that if the statement had been killed on the master, the slave would stop. (Bug #2983 [<http://bugs.mysql.com/2983>])
- The `--local-load` option of `mysqlbinlog` now requires an argument.
- Fixed a segmentation fault when running `LOAD DATA FROM MASTER` after `RESET SLAVE`. (Bug #2922 [<http://bugs.mysql.com/2922>])
- **mysqlbinlog --read-from-remote-server** read all binary logs following the one that was requested. It now stops at the end of the requested file, the same as it does when reading a local binary log. There is an option `--to-last-log` to get the old behavior. (Bug #3204 [<http://bugs.mysql.com/3204>])
- Fixed **mysqlbinlog --read-from-remote-server** to print the exact positions of events in the "a#" lines. (Bug #3214 [<http://bugs.mysql.com/3214>])
- Fixed a rare error condition that caused the slave SQL thread spuriously to print the message `Binlog has bad magic number` and stop when it was not necessary to do so. (Bug #3401 [<http://bugs.mysql.com/3401>])
- Fixed the `Exec_master_log_pos` column and its disk image in the `relay-log.info` file to be correct if the master had version 3.23. (The value was too big by six bytes.) This bug does not exist in MySQL 5.0. (Bug #3400 [<http://bugs.mysql.com/3400>])
- Fixed **mysqlbinlog** not to forget to print a `USE` statement under rare circumstances where the binary log contained a `LOAD DATA INFILE` statement. (Bug #3415 [<http://bugs.mysql.com/3415>])
- Fixed a memory corruption when replicating a `LOAD DATA INFILE` when the master had version 3.23. Some smaller problems remain in this setup, See Section 6.7, "Replication Features and Known Problems". (Bug #3422 [<http://bugs.mysql.com/3422>])
- Multiple-table `DELETE` statements were always replicated by the slave if there were some `--replicate*-ignore-table` options and no `--replicate*-do-table` options. (Bug #3461 [<http://bugs.mysql.com/3461>])
- Fixed a crash of the MySQL slave server when it was built with `--with-debug` and replicating itself. (Bug #3568 [<http://bugs.mysql.com/3568>])
- Fixed that in some replication error messages, a very long query caused the rest of the message to be invisible (truncated), by putting the query last in the message. (Bug #3357 [<http://bugs.mysql.com/3357>])
- Fixed a bug in `REPAIR TABLE` that resulted sometimes in a corrupted table, if the table con-

tained FULLTEXT indexes and many words of different lengths that are considered equal (which is possible in certain collations, such as latin1_german2_ci or utf8_general_ci). (Bug #3835 [<http://bugs.mysql.com/3835>])

- Fixed a crash of **mysqld** that was started with binary logging disabled, but with a non-zero value for the `expire_logs_days` system variable. (Bug #3807 [<http://bugs.mysql.com/3807>])
- If `server-id` was not set using startup options but with `SET GLOBAL`, the replication slave still complained that it was not set. (Bug #3829)

D.2.13. Changes in release 4.1.1 (01 Dec 2003)

This release includes all fixes in MySQL 4.0.16 and most of the fixes in MySQL 4.0.17.

Functionality added or changed:

- **Important note:** If you upgrade to InnoDB-4.1.1 or higher, you cannot downgrade to a version lower than 4.1.1 any more! That is because earlier versions of InnoDB are not aware of multiple tablespaces.
- **Warning: Incompatible change!** Renamed the C API `mysql_prepare_result()` function to `mysql_get_metadata()` because the old name was confusing.
- **Warning: Incompatible change!** Client authentication now is based on 41-byte passwords in the `user` table, not 45-byte passwords as in 4.1.0. Any 45-byte passwords created for 4.1.0 must be reset after running the **mysql_fix_privilege_tables** script.
- Added `secure_auth` global server system variable and `--secure-auth` server option that disallow authentication for accounts that have old (pre-4.1.1) passwords.
- Added `--secure-auth` option to **mysql** command-line client. If this option is set, the client refuses to send passwords in old (pre-4.1.1) format.
- Table aliases are not case sensitive if `lower_case_table_names` is non-zero.
- The `--old-protocol` option for **mysqld** is no longer supported and has been removed.
- Renamed `bdb_version` system variable to `version_bdb`.
- MyISAM tables now use a better checksum algorithm (if checksum is enabled with `CREATE TABLE ... CHECKSUM=1`). Old tables will appear to have incorrect checksum, and should be repaired.
- New `CHECKSUM TABLE` statement for reporting table checksum values.
- Added `character_set_client`, `character_set_connection`, `character_set_database`, `character_set_results`, `character_set_server`, `character_set_system`, `collation_connection`, `collation_database`, and `collation_server` system variables to provide information about character sets and collations.
- It is now possible to create multiple key caches, assign table indexes to particular caches, and to preload indexes into caches. See Section 13.5.5.1, “CACHE INDEX Syntax”. See Section 13.5.5.4, “LOAD INDEX INTO CACHE Syntax”. Structured system variables are introduced as a means of grouping related key cache parameters. See Section 9.4.1, “Structured System Variables”.
- Added `preload_buffer_size` system variable.
- New `COERCIBILITY()` function to return the collation coercibility of a string.
- The `--quote-names` option for **mysqldump** now is enabled by default.

- **mysqldump** now includes a statement in the dump output to set `FOREIGN_KEY_CHECKS` to 0 to avoid problems with tables having to be reloaded in a particular order when the dump is reloaded. The existing `FOREIGN_KEY_CHECKS` value is saved and restored.
- You can revoke all privileges from a user with `REVOKE ALL PRIVILEGES, GRANT FROM user_list`.
- Added `IGNORE` option for `DELETE` statement.
- MySQL source distributions now also include the MySQL Internals Manual `internals.texi`.
- Added `mysql_set_server_option()` C API client function to allow multiple statement handling in the server to be enabled or disabled.
- The `mysql_next_result()` C API function now returns -1 if there are no more result sets.
- Renamed `CLIENT_MULTI_QUERIES` connect option flag to `CLIENT_MULTI_STATEMENTS`. To allow for a transition period, the old option continues to be recognized for a while.
- Require `DEFAULT` before table and database default character set. This enables us to use `ALTER TABLE tbl_name ... CHARACTER SET=...` to change the character set for all `CHAR`, `VARCHAR`, and `TEXT` columns in a table.
- Added `MATCH ... AGAINST(... WITH QUERY EXPANSION)` and the `ft_query_expansion_limit` system variable.
- Removed unused `ft_max_word_len_for_sort` system variable.
- Removed unused `ft_max_word_len_for_sort` variable from **myisamchk**.
- Full-text search now supports multi-byte character sets and the Unicode `utf8` character set. (The Unicode `ucs2` character set is not yet supported.)
- Phrase search in `MATCH ... AGAINST (... IN BOOLEAN MODE)` no longer matches partial words.
- Added aggregate function `BIT_XOR()` for bitwise XOR operations.
- Replication over SSL now works.
- The `START SLAVE` statement now supports an `UNTIL` clause for specifying that the slave SQL thread should be started but run only until it reaches a given position in the master's binary logs or in the slave's relay logs.
- Produce warnings even for single-row `INSERT` statements, not just for multiple-row `INSERT` statements. Previously, it was necessary to set `SQL_WARNINGS=1` to generate warnings for single-row statements.
- Added `delimiter (\d)` command to the **mysql** command-line client for changing the statement delimiter (terminator). The default delimiter is semicolon.
- `CHAR`, `VARCHAR`, and `TEXT` columns now have lengths measured in characters rather than in bytes. The character size depends on the column's character set. This means, for example, that a `CHAR(n)` column for a multi-byte character set takes more storage than before. Similarly, index values on such columns are measured in characters, not bytes.
- `LIMIT` no longer accepts negative arguments (they used to be treated as very big positive numbers before).
- The `DATABASE()` function now returns `NULL` rather than the empty string if there is no database selected.

- Added `--sql-mode=NO_AUTO_VALUE_ON_ZERO` option to suppress the usual behavior of generating the next sequence number when zero is stored in an `AUTO_INCREMENT` column. With this mode enabled, zero is stored as zero; only storing `NULL` generates a sequence number.
- Added `DROP USER 'user_name'@'host_name'` statement to drop an account that has no privileges.
- The interface to aggregate user-defined functions has changed a bit. You must now declare a `xxx_clear()` function for each aggregate function `XXX()`. `xxx_clear()` is used instead of `xxx_reset()`.
- Added new `ADDTIME()`, `DATE()`, `DATEDIFF()`, `LAST_DAY()`, `MAKEDATE()`, `MAKETIME()`, `MICROSECOND()`, `SUBTIME()`, `TIME()`, `TIMEDIFF()`, `TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and `WEEKOFYEAR()` functions.
- Added new syntax for `ADDDATE()` and `SUBDATE()`. The second argument now may be a number representing the number of days to be added to or subtracted from the first date argument.
- Added new type values `DAY_MICROSECOND`, `HOURL_MICROSECOND`, `MINUTE_MICROSECOND`, `SECOND_MICROSECOND`, and `MICROSECOND` for `DATE_ADD()`, `DATE_SUB()`, and `EXTRACT()`.
- Added new `%f` microseconds format specifier for `DATE_FORMAT()` and `TIME_FORMAT()`.
- All queries in which at least one `SELECT` does not use indexes properly now are written to the slow query log when long log format is used.
- It is now possible to create a `MERGE` table from `MyISAM` tables in different databases. Formerly, all the `MyISAM` tables had to be in the same database, and the `MERGE` table had to be created in that database as well.
- Added new `COMPRESS()`, `UNCOMPRESS()`, and `UNCOMPRESSED_LENGTH()` functions.
- When using `SET sql_mode='mode'` for a complex mode (such as `ANSI`), we now update the `sql_mode` variable to include all the individual options implied by the complex mode.
- Added the OLAP (On-Line Analytical Processing) function `ROLLUP`, which provides summary rows for each `GROUP BY` level.
- Added `SQLSTATE` codes for all server errors.
- Added `mysql_sqlstate()` and `mysql_stmt_sqlstate()` C API client functions that return the `SQLSTATE` error code for the last error.
- `TIME` columns with hour values greater than 24 were returned incorrectly to the client.
- `ANALYZE TABLE`, `OPTIMIZE TABLE`, `REPAIR TABLE`, and `FLUSH` statements are now stored in the binary log and thus replicated to slaves. This logging does not occur if the optional `NO_WRITE_TO_BINLOG` keyword (or its alias `LOCAL`) is given. Exceptions are that `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK` are not logged in any case. For a syntax example, see Section 13.5.5.2, “FLUSH Syntax”.
- New global system variable `relay_log_purge` to enable or disable automatic relay log purging.
- `LOAD DATA` now produces warnings that can be fetched with `SHOW WARNINGS`.
- Added support for syntax `CREATE TABLE table2 (LIKE table1)` that creates an empty table `table2` with a definition that is exactly the same as `table1`, including any indexes.
- `CREATE TABLE tbl_name (...) TYPE=storage_engine` now generates a warning if the named storage engine is not available. The table is still created as a `MyISAM` table, as be-

fore.

- Most subqueries are now much faster than before.
- Added `PURGE BINARY LOGS` as an alias for `PURGE MASTER LOGS`.
- Disabled the `PURGE LOGS` statement that was added in version 4.1.0. The statement now should be issued as `PURGE MASTER LOGS` or `PURGE BINARY LOGS`.
- Added `SHOW BDB LOGS` as an alias for `SHOW LOGS`.
- Added `SHOW MASTER LOGS` as an alias for `SHOW BINARY LOGS`. (In 4.1.0, `SHOW MASTER LOGS` was renamed to `SHOW BINARY LOGS`. Now you can use either one.)
- Added `Slave_IO_State` and `Seconds_Behind_Master` columns to the output of `SHOW SLAVE STATUS`. `Slave_IO_State` indicates the state of the slave I/O thread, and `Seconds_Behind_Master` indicates the number of seconds by which the slave is late compared to the master.
- The `--lower-case-table-names=1` server option now also makes aliases case insensitive. (Bug #534 [<http://bugs.mysql.com/534>])
- Changed that the relay log is flushed to disk by the slave I/O thread every time it reads a relay log event. This reduces the risk of losing some part of the relay log in case of brutal crash.

Bugs fixed:

- Fixed **mysql** parser not to erroneously interpret `';` character within `/* ... */` comment as statement terminator.
- Fixed merging types and length of result set columns for `UNION` operations. The types and lengths now are determined taking into account values for all `SELECT` statements in the `UNION`, not just the first `SELECT`.
- Fixed a bug in privilege handling that caused connections from certain IP addresses to be assigned incorrect database-level privileges. A connection could be assigned the database privileges of the previous successful authentication from one of those IP addresses, even if the IP address username and database name were different. (Bug #1636 [<http://bugs.mysql.com/1636>])
- Error-handling functions were not called properly when an error resulted from `[CREATE | REPLACE | INSERT] ... SELECT` statements.
- `HASH`, `BTREE`, `RTREE`, `ERRORS`, and `WARNINGS` no longer are reserved words. (Bug #724 [<http://bugs.mysql.com/724>])
- Fix for bug in `ROLLUP` when all tables were `const` tables. (Bug #714 [<http://bugs.mysql.com/714>])
- Fixed a bug in `UNION` that prohibited `NULL` values from being inserted into result set columns where the first `SELECT` of the `UNION` retrieved `NOT NULL` columns. The type and `max_length` of the result column is now defined based on all `UNION` parts.
- Fixed name resolution of columns of reduced subqueries in unions. (Bug #745 [<http://bugs.mysql.com/745>])
- Fixed memory overrun in subqueries in select list with `WHERE` clause bigger than outer query `WHERE` clause. (Bug #726 [<http://bugs.mysql.com/726>])
- Fixed a bug that caused `MyISAM` tables with `FULLTEXT` indexes created in 4.0.x to be unreadable in 4.1.x.
- Fixed a data loss bug in `REPAIR TABLE ... USE_FRM` when used with tables that con-

tained `TIMESTAMP` columns and were created in 4.0.x.

- Fixed reduced subquery processing in `ORDER BY/GROUP BY` clauses. (Bug #442 [<http://bugs.mysql.com/442>])
- Fixed name resolution of outer columns of subquery in `INSERT/REPLACE` statements. (Bug #446 [<http://bugs.mysql.com/446>])
- Fixed bug in marking columns of reduced subqueries. (Bug #679 [<http://bugs.mysql.com/679>])
- Fixed a bug that made `CREATE FULLTEXT INDEX` syntax illegal.
- Fixed a crash when a `SELECT` that required a temporary table (marked by `Using temporary` in `EXPLAIN` output) was used as a derived table in `EXPLAIN` command. (Bug #251 [<http://bugs.mysql.com/251>])
- Fixed a rare table corruption bug in `DELETE` from a big table with a **new** (created by MySQL-4.1) full-text index.
- `LAST_INSERT_ID()` now returns 0 if the last `INSERT` statement didn't insert any rows.
- Fixed missing last character in function output. (Bug #447 [<http://bugs.mysql.com/447>])
- Fixed a rare replication bug when a transaction spanned two or more relay logs, and the slave was stopped while executing the part of the transaction that was in the second or later relay log. Then replication would resume at the beginning of the second or later relay log, which was incorrect. (It should resume at `BEGIN`, in the first relay log.) (Bug #53 [<http://bugs.mysql.com/53>])
- `CONNECTION_ID()` now is properly replicated. (Bug #177 [<http://bugs.mysql.com/177>])
- The new `PASSWORD()` function in 4.1 is now properly replicated. (Bug #344 [<http://bugs.mysql.com/344>])
- Fixed a bug with double freed memory.
- Fixed a crashing bug in `UNION` operations that involved temporary tables.
- Fixed a bug that under certain circumstances could allow a privilege escalation via database wildcards in `GRANT`. (Bug #3924 [<http://bugs.mysql.com/3924>], CAN-2004-0957 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0957>])
- Fixed a crashing bug in `DERIVED TABLES` when `EXPLAIN` is used on a `DERIVED TABLES` with a join.
- Fixed a crashing bug in `DELETE` with `ORDER BY` and `LIMIT` caused by an uninitialized array of reference pointers.
- Fixed a bug in the `USER()` function caused by an error in the size of the allocated string.
- Fixed a crashing bug when attempting to create a table containing a spatial (GIS) column with a storage engine that does not support spatial types.
- Fixed a crashing bug in `UNION` caused by the empty select list and a non-existent column being used in some of the individual `SELECT` statements.
- Fixed a replication bug with a 3.23 master and a 4.0 slave: The slave lost the replicated temporary tables if `FLUSH LOGS` was issued on the master. (Bug #254 [<http://bugs.mysql.com/254>])
- Fixed a security bug: A server compiled without SSL support still allowed connections by users who had the `REQUIRE SSL` option specified for their accounts.
- When an undefined user variable was used in a updating query on the master (such as `INSERT INTO t VALUES(@a)`, where `@a` had never been set by this connection before), the slave

could replicate the query incorrectly if a previous transaction on the master used a user variable of the same name. (Bug #1331 [<http://bugs.mysql.com/1331>])

- Fixed bug with prepared statements: Using the `?` prepared statement parameter as the argument to certain functions or statement clauses caused a server crash when `mysql_prepare()` was invoked. (Bug #1500 [<http://bugs.mysql.com/1500>])
- Fixed bug with prepared statements: after call to `mysql_prepare` placeholders became allowed in all consequent statements, even if they are not prepared (Bug #1946 [<http://bugs.mysql.com/1946>])
- `SLAVE START` (which is a deprecated syntax, `START SLAVE` should be used instead) could crash the slave. (Bug #2516 [<http://bugs.mysql.com/2516>])
- Fixed bug in `ALTER TABLE RENAME`, when rename to the table with the same name in another database silently dropped destination table if it existed. (Bug #2628 [<http://bugs.mysql.com/2628>])
- When not specify hostname in `SET PASSWORD FOR user` it's now defaulted to `%` instead of the current host.

D.2.14. Changes in release 4.1.0 (03 Apr 2003: Alpha)

Functionality added or changed:

- Renamed `SHOW MASTER LOGS` statement to `SHOW BINARY LOGS`.
- Allow `DEFAULT(col_name)` in expressions; it produces the column's default value.
- Added `--compatible` option to **mysqldump** for producing output that is compatible with other database systems or with older MySQL servers.
- The `--opt` option for **mysqldump** now is enabled by default, as are all the options implied by `--opt`.
- New `CHARSET()` and `COLLATION()` functions to return the character set and collation of a string.
- Allow index type to be specified explicitly for some storage engines via `USING type_name` syntax in index definition.
- New function `IS_USED_LOCK()` for determining the connection identifier of the client that holds a given advisory lock.
- New more secure client authentication based on 45-byte passwords in the `user` table. (CVE-2000-0981 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0981>])
- Added `old-password` command to **mysqladmin** for changing password but storing it using the old password-hashing format.
- New `CRC32()` function to compute cyclic redundancy check value.
- On Windows, we are now using shared memory to communicate between server and client when they are running on the same machine and you are connecting to `localhost`.
- `REPAIR TABLE` of MyISAM tables now uses less temporary disk space when sorting char columns.
- `DATE/DATETIME` checking is now a bit stricter to support the ability to automatically distinguish between date, datetime, and time with microseconds. For example, dates of type `YYYYM-MDD HHMMDD` are no longer supported; you must either have separators between each

TIME part or not at all.

- Server side help for all MySQL functions. One can now type `help week` in the **mysql** client and get help for the `week()` function.
- Added new `mysql_get_server_version()` C API client function.
- Fixed bug in `libmysqlclient` that fetched column defaults.
- Fixed bug in `mysql` command-line client in interpreting quotes within comments. (Bug #539 [<http://bugs.mysql.com/539>])
- Added `record_in_range()` method to MERGE tables to be able to choose the right index when there are many to choose from.
- Replication now works with `RAND()` and user variables `@var`.
- Allow one to change mode for `ANSI_QUOTES` on the fly.
- `EXPLAIN SELECT` now can be killed. See Section 13.5.5.3, “KILL Syntax”.
- `REPAIR TABLE` and `OPTIMIZE TABLE` now can be killed. See Section 13.5.5.3, “KILL Syntax”.
- Allow empty index lists to be specified for `USE INDEX`, `IGNORE INDEX`, and `FORCE INDEX`.
- `DROP TEMPORARY TABLE` now drops only temporary tables and doesn't end transactions.
- Added support for UNION in derived tables.
- **Warning: Incompatible change!** `TIMESTAMP` is now returned as a string of type `'YYYY-MM-DD HH:MM:SS'` and different timestamp lengths are not supported.

This change was necessary for SQL standards compliance. In a future version, a further change will be made (backward compatible with this change), allowing the timestamp length to indicate the desired number of digits of fractions of a second.

- New faster client/server protocol that supports prepared statements, bound parameters, and bound result columns, binary transfer of data, warnings.
- Added database and real table name (in case of alias) to the `MYSQL_FIELD` structure.
- Multi-line queries: You can now issue several queries at once and then read the results in one go.
- In `CREATE TABLE foo (a INT not null primary key)` the `PRIMARY` word is now optional.
- In `CREATE TABLE` the attribute `SERIAL` is now an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.
- `SELECT ... FROM DUAL` is an alias for `SELECT ...` (To be compatible with some other databases).
- If one creates a too long `CHAR/VARCHAR` it's now automatically changed to `TEXT` or `BLOB`; One get a warning in this case.
- One can specify the different `BLOB/TEXT` types with the syntax `BLOB(length)` and `TEXT(length)`. MySQL automatically changes it to one of the internal `BLOB/TEXT` types.
- `CHAR BYTE` is an alias for `CHAR BINARY`.
- `VARCHARACTER` is an alias for `VARCHAR`.

- New operators `integer MOD integer` and `integer DIV integer`. `DIV` is now a reserved word.
- `SERIAL DEFAULT VALUE` added as an alias for `AUTO_INCREMENT`.
- `TRUE` and `FALSE` added as alias for 1 and 0, respectively.
- Aliases are now forced in derived tables, as per standard SQL.
- Fixed `SELECT .. LIMIT 0` to return proper row count for `SQL_CALC_FOUND_ROWS`.
- One can specify many temporary directories to be used in a round-robin fashion with: `--tmpdir=dirname1:dirname2:dirname3`.
- Subqueries: `SELECT * from t1 where t1.a=(SELECT t2.b FROM t2)`.
- Derived tables:

```
SELECT a.col1, b.col2
      FROM (SELECT MAX(col1) AS col1 FROM root_table) a,
           other_table b
      WHERE a.col1=b.col1;
```
- Character sets to be defined per column, table and database.
- Unicode (UTF8) support.
- New `CONVERT(... USING ...)` syntax for converting string values between character sets.
- BTREE index on MEMORY (HEAP) tables.
- Faster embedded server (new internal communication protocol).
- One can add a comment per column in `CREATE TABLE`.
- `SHOW FULL COLUMNS FROM tbl_name` shows column comments.
- `ALTER DATABASE`.
- Support for GIS (Geometrical data). See Chapter 18, *Spatial Extensions in MySQL*.
- `SHOW [COUNT(*)] WARNINGS` shows warnings from the last command.
- One can specify a column type for a column in `CREATE TABLE ... SELECT` by defining the column in the `CREATE` part.

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```
- `expr SOUNDS LIKE expr` same as `SOUNDEX(expr)=SOUNDEX(expr)`.
- Added new `VARIANCE(expr)` function returns the variance of `expr`
- One can create a table from the existing table using `CREATE [TEMPORARY] TABLE [IF NOT EXISTS] table (LIKE table)`. The table can be either normal or temporary.
- New options `--reconnect` and `--skip-reconnect` for the **mysql** client, to reconnect automatically or not if the connection is lost.
- `START SLAVE (STOP SLAVE)` no longer returns an error if the slave is started (stopped); it returns a warning instead.
- `SLAVE START` and `SLAVE STOP` are no longer accepted by the query parser; use `START`

SLAVE and STOP SLAVE instead.

D.3. Changes in release 4.0.x (Production)

Version 4.0 of the MySQL server includes many enhancements and new features:

- The InnoDB storage engine is now included in the standard binaries, adding transactions, row-level locking, and foreign keys. See Chapter 15, *The InnoDB Storage Engine*.
- A query cache, offering vastly increased performance for many applications. By caching complete result sets, later identical queries can return instantly. See Section 5.12, “The MySQL Query Cache”.
- Improved full-text indexing with boolean mode, truncation, and phrase searching. See Section 12.6, “Full-Text Search Functions”.
- Enhanced MERGE tables, now supporting INSERT statements and AUTO_INCREMENT. See Section 14.2, “The MERGE Storage Engine”.
- UNION syntax in SELECT. See Section 13.1.7.2, “UNION Syntax”.
- Multiple-table DELETE statements. See Section 13.1.1, “DELETE Syntax”.
- libmysqld, the embedded server library. See Section 24.2.16, “libmysqld, the Embedded MySQL Server Library”.
- Additional GRANT privilege options for even tighter control and security. See Section 13.5.1.3, “GRANT and REVOKE Syntax”.
- Management of user resources in the GRANT system, particularly useful for ISPs and other hosting providers. See Section 5.7.4, “Limiting Account Resources”.
- Dynamic server variables, allowing configuration changes to be made without having to stop and restart the server. See Section 13.5.3, “SET Syntax”.
- Improved replication code and features. See Chapter 6, *Replication in MySQL*.
- Numerous new functions and options.
- Changes to existing code for enhanced performance and reliability.

For a full list of changes, please refer to the changelog sections for each individual 4.0.x release.

D.3.1. Changes in release 4.0.25 (not released yet)

Functionality added or changed:

- Added `--with-big-tables` compilation option to **configure**. (Previously it was necessary to pass `-DBIG_TABLES` to the compiler manually in order to enable large table support.) Section 2.8.2, “Typical **configure** Options” for details.

Bugs fixed:

- InnoDB: In `DROP DATABASE`, check for all referencing tables from other databases before dropping any tables. (Bug #10335 [<http://bugs.mysql.com/10335>])
- Fixed a problem with incorrect constant propagation resulting in incorrect evaluation of `AND/`

OR queries. (Bug #10095 [<http://bugs.mysql.com/10095>])

- Fixed wrong buffer usage for auto-increment key with blob part that caused CHECK TABLE to report that the table was wrong. (Bug #10045 [<http://bugs.mysql.com/10045>])
- No error was raised for BOOLEAN full-text searches for storage engines that do not support full-text. (Bug #7709 [<http://bugs.mysql.com/7709>])
- The test in **configure** to see whether CXX specified **gcc** failed if **gcc** was specified as a full path-name. (Bug #9690 [<http://bugs.mysql.com/9690>])
- In the `mysql_real_escape_string()` C API function, when a multi-byte character is encountered that is illegal in the current character set, escape only the first byte, not each byte. This avoids creating a valid character from an invalid one. (Bug #9864 [<http://bugs.mysql.com/9864>]; this is a backport of Bug #8378 [<http://bugs.mysql.com/8378>] from MySQL 4.1.11 to 4.0.25)
- Fixed a deadlock resulting from use of FLUSH TABLES WITH READ LOCK while an INSERT DELAYED statement is in progress. (Bug #7823 [<http://bugs.mysql.com/7823>])
- Fixed a segmentation fault in **mysqlcheck** that occurred when the last table checked in `--auto-repair` mode returned an error (such as the table being a MERGE table). (Bug #9492 [<http://bugs.mysql.com/9492>])
- Fixed faulty display of TIMESTAMP columns retrieved as `col_name+0` while the new system variable is set to 1. (Bug #8894 [<http://bugs.mysql.com/8894>])
- Queries containing CURRENT_USER() incorrectly were registered in the query cache. (Bug #9796 [<http://bugs.mysql.com/9796>])
- Fixed problems with static variables to allow building on Fedora Core 3. (Bug #6554 [<http://bugs.mysql.com/6554>])
- An UPDATE that updated only some of the columns in a multiple-column index could result in a loop. (Bug #8942 [<http://bugs.mysql.com/8942>])
- REPAIR TABLE did not invalidate query results in the query cache that were generated from the table. (Bug #8480 [<http://bugs.mysql.com/8480>])
- Fixed a bug that caused concurrent inserts to be allowed into the tables in the SELECT ... UNION ... part of INSERT ... SELECT ... UNION This could result in the incorrect order of queries in the binary log. (Bug #9922 [<http://bugs.mysql.com/9922>])
- Fixed a bug that under certain circumstances could allow a privilege escalation via database wildcards in GRANT. (Bug #3924 [<http://bugs.mysql.com/3924>], CAN-2004-0957 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0957>])
- <=> was not properly comparing NULL values in the WHERE clause of outer joins. (Bug #8711 [<http://bugs.mysql.com/8711>])
- InnoDB: Fixed a bug: MySQL-4.0.23 and 4.0.24 could complain that an InnoDB table created with MySQL-3.23.49 or earlier was in the new compact InnoDB table format of 5.0.3 or later, and InnoDB would refuse to use that table. (The same bug exists in 4.1.8 - 4.1.10.) There is nothing wrong with the table, it is mysqld that is in error. Workaround: wait that 4.0.25 or 4.1.11 is released before doing an upgrade, or dump the table and recreate it with any MySQL version >= 3.23.50 before upgrading to 4.0.23 or 4.0.24.

D.3.2. Changes in release 4.0.24 (04 Mar 2005)

Functionality added or changed:

- Security improvement: The server creates `.frm`, `.MYD`, `.MYI`, `.MRG`, `.ISD`, and `.ISM` table

files only if a file with the same name does not already exist. Thanks to Stefano Di Paola <stefano.dipaola@wisec.it> for finding and informing us about this issue. (CAN-2005-0711 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2005-0711>])

- Security improvement: User-defined functions should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`, `xxx_deinit()`, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` functions. **mysqld** by default no longer loads UDFs unless they have at least one auxiliary symbol defined in addition to the main symbol. The `--allow-suspicious-udfs` option controls whether UDFs that have only an `xxx` symbol can be loaded. By default, the option is off. **mysqld** also checks UDF filenames when it reads them from the `mysql.func` table and rejects those that contain directory pathname separator characters. (It already checked names as given in `CREATE FUNCTION` statements.) See Section 27.2.3.1, “UDF Calling Sequences for simple functions”, Section 27.2.3.2, “UDF Calling Sequences for aggregate functions”, and Section 27.2.3.6, “User-defined Function Security Precautions”. Thanks to Stefano Di Paola <stefano.dipaola@wisec.it> for finding and informing us about this issue. (CAN-2005-0709 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2005-0709>], CAN-2005-0710 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2005-0710>])
- InnoDB: Added configuration option and settable global variable `innodb_autoextend_increment` for setting the size in megabytes by which InnoDB tablespaces are extended when they become full. The default value is 8, corresponding to the fixed increment of 8MB in previous versions of MySQL.
- InnoDB: Do not acquire an internal InnoDB table lock in `LOCK TABLES` if `AUTOCOMMIT=1`. This helps in porting old MyISAM applications to InnoDB. InnoDB table locks in that case caused deadlocks very easily.

Bugs fixed:

- `AES_DECRYPT(col_name, key)` could fail to return NULL for invalid values in `col_name`, if `col_name` was declared as NOT NULL. (Bug #8669 [<http://bugs.mysql.com/8669>])
- `FOUND_ROWS()` returned an incorrect value after a `SELECT SQL_CALC_FOUND_ROWS DISTINCT` statement that selected constants and included `GROUP BY` and `LIMIT` clauses. (Bug #7945 [<http://bugs.mysql.com/7945>])
- Queries of the form `(SELECT ...) ORDER BY ...` were being treated as a UNION. This improperly resulted in only distinct values being returned (because UNION by default eliminates.) (Bug #7672 [<http://bugs.mysql.com/7672>])
- Index cardinality was not being updated properly for TEMPORARY tables under some circumstances, such as `CREATE TABLE ... SELECT` followed by `ANALYZE TABLE`. (Bug #7519 [<http://bugs.mysql.com/7519>])
- Fixed a server crash caused by `DELETE FROM tbl_name ... WHERE ... ORDER BY tbl_name.col_name` when the `ORDER BY` column was qualified with the table name. (Bug #8392 [<http://bugs.mysql.com/8392>])
- Fixed a bug in `MATCH ... AGAINST` in natural language mode that could cause a server crash if the FULLTEXT index was not used in a join (`EXPLAIN` did not show `fulltext` join mode) and the search query matched no rows in the table (Bug #8522 [<http://bugs.mysql.com/8522>]).
- Platform and architecture information in version information produced for `--version` option on Windows was always Win95/Win98 (i32). More accurately determine platform as Win32 or Win64 for 32-bit or 64-bit Windows, and architecture as ia32 for x86, ia64 for Itanium, and axp for Alpha. (Bug #4445 [<http://bugs.mysql.com/4445>])
- Fixed an optimization problem that allowed a negative number to be stored in a `DOUBLE UN-`

SIGNED column when it was assigned a value from a signed DOUBLE column. (Bug #7700 [<http://bugs.mysql.com/7700>])

- Fixed a failure of multiple-table updates to replicate properly on slave servers when `--replicate-*-table` options had been specified. (Bug #7011 [<http://bugs.mysql.com/7011>])
- Renamed `set_bit()` and `clear_bit()` functions in source code to avoid a conflict with functions of the same names in Linux kernel header files. (Bug #7971 [<http://bugs.mysql.com/7971>])
- Part of the information being used to cache access-permission lookups was not always reinitialized properly, particularly for connections from localhost on Windows. The result was connection failures that appeared to occur randomly. (Bug #5569 [<http://bugs.mysql.com/5569>])
- Corrected a problem with the `QUOTE()` function returning bad results. (Bug #8248 [<http://bugs.mysql.com/8248>])
- Fixed a problem where `INSERT INTO ... SELECT` failed when the source and target table were the same. (Bug #6034 [<http://bugs.mysql.com/6034>])
- Fixed a problem where RPM installation on Linux as a non-privileged user would result in incomplete installation. (Bug #7347 [<http://bugs.mysql.com/7347>])
- Change thread stack size used for building Linux RPM distributions to avoid warnings about stack size during server startup. (Bug #6226 [<http://bugs.mysql.com/6226>])
- Fixed a symlink vulnerability in the `mysqlaccess` script. Reported by Javier Fernandez-Sanguino Pena and Debian Security Audit Team [<http://www.debian.org/security/audit>]. (CAN-2005-0004 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2005-0004>])
- Fixed support for C API function `mysql_list_fields()`, which was accidentally broken in 4.0.22 (Bug#6761)
- Make `query_cache_wlock_invalidate` system variable visible in `SHOW VARIABLES` output. (Bug #7594 [<http://bugs.mysql.com/7594>])
- Fixed a bug which caused `FROM_UNIXTIME()` function to return NULL for zero argument instead of the Epoch. (Bug #7515 [<http://bugs.mysql.com/7515>])
- Now in datetime values two digit year is interpreted as year in 20th or 21st century even with zero month and day. (Bug #7297 [<http://bugs.mysql.com/7297>])
- Fixed a bug in `QUOTE` function when used in conjunction with some other string functions. This lead to severe buffer overflow and server crashing. (Bug #7495 [<http://bugs.mysql.com/7495>])
- InnoDB: Work around a problem in AIX 5.1 patched with ML7 security patch: InnoDB would refuse to open its `ibdata` files, complaining about an operating system error 0.
- InnoDB: Fixed a memory corruption bug if one created a table with a primary key that contained at least two column prefixes. An example: `CREATE TABLE t(a char(100), b tinyblob, PRIMARY KEY(a(5), b(10)))`.
- InnoDB: Use native `tmpfile()` function on Netware. All InnoDB temporary files are created under `sys:\tmp`. Previously, InnoDB temporary files were never deleted on Netware.
- InnoDB: Honor the `--tmpdir` startup option when creating temporary files. Previously, InnoDB temporary files were always created in the temporary directory of the operating system. On Netware, InnoDB will continue to ignore `--tmpdir`. (Bug #5822 [<http://bugs.mysql.com/5822>])
- InnoDB: Fix a theoretical hang over the adaptive hash latch in InnoDB if one runs `INSERT ... SELECT ...` (binlog not enabled), or a multi-table `UPDATE` or `DELETE`, and only the read tables are InnoDB type, the rest are MyISAM; this also fixes bug #7879 for InnoDB type

tables. (Bug #7879 [<http://bugs.mysql.com/7879>])

- InnoDB: Fixed a bug: 32-bit **mysqld** binaries built on HP-UX-11 did not work with InnoDB files greater than 2 GB in size. (Bug #6189 [<http://bugs.mysql.com/6189>])
- InnoDB: Fixed a bug: InnoDB failed to drop a table in the background drop queue if the table was referenced by a foreign key constraint.
- InnoDB: Fixed a bug: if we dropped a table where an INSERT was waiting for a lock to check a FOREIGN KEY constraint, then an assertion would fail in `lock_reset_all_on_table()`, since that operation assumes no waiting locks on the table or its records.
- Fixed that, when encountering a ``disk full" or ``quota exceeded" write error, MyISAM sometimes didn't sleep and retry the write, thus resulting in a corrupted table. (Bug #7714 [<http://bugs.mysql.com/7714>])
- Fixed that a slave could crash after replicating many ANALYZE TABLE, OPTIMIZE TABLE, or REPAIR TABLE statements from the master. (Bug #6461 [<http://bugs.mysql.com/6461>], Bug #7658 [<http://bugs.mysql.com/7658>])
- Fixed a bug where MySQL was allowing concurrent updates (inserts, deletes) to a table if binary logging is enabled. Changed to ensure that all updates are executed in a serialized fashion, because they are executed serialized when binlog is replayed. (Bug #7879 [<http://bugs.mysql.com/7879>])
- Fixed a bug that caused the slave to stop on statements that produced an error on the master. (Bug #8412 [<http://bugs.mysql.com/8412>])
- Documented problem with using `mysqldump` in 4.0.x to dump `TIMESTAMP(2)` and `TIMESTAMP(4)` column types. (Bug #6530 [<http://bugs.mysql.com/6530>])

D.3.3. Changes in release 4.0.23 (18 Dec 2004)

Note: Due to a **libtool**-related bug in the source distribution, the creation of shared `libmysql-client` libraries was not possible (the resulting files were missing the `.so` file name extension). The file `ltmain.sh` was updated to fix this problem and the resulting source distribution was released as `mysql-4.0.23a.tar.gz`. This modification did not affect the binary packages. (Bug #7401 [<http://bugs.mysql.com/7401>])

Functionality added or changed:

- Added `--hex-blob` option to **mysqldump** for dumping binary string columns using hexadecimal notation.
- Added `mysql_hex_string()` C API function that hex-encodes a string.
- InnoDB: Do not periodically write `SHOW INNODB STATUS` information to a temporary file unless the configuration option `innodb_status_file=1` is set.
- InnoDB: Made the foreign key parser better aware of quotes. (Bug #6340 [<http://bugs.mysql.com/6340>])
- `mysqlbinlog` now prints an informative commented line (thread id, timestamp, server id, etc) before each `LOAD DATA INFILE`, like it does for other queries; unless `--short-form` is used.

Bugs fixed:

- Corrected accounts in the `mysql.user` table in Windows distributions that had been created with a `Host` value of `build` rather than `%`. (Bug #6000 [<http://bugs.mysql.com/6000>])
- Prevent adding `CREATE TABLE ... SELECT` query to the binary log when the insertion of new records partially failed. (Bug #6682 [<http://bugs.mysql.com/6682>])
- Fixed bug which caused `FROM_UNIXTIME()` function to return wrong result if the argument was too big. (Bug #6439 [<http://bugs.mysql.com/6439>])
- Fixed bug which caused MySQL server to store wrong values in `TIMESTAMP` columns and give wrong results for `UNIX_TIMESTAMP()` function if it was run in time zone with leap seconds. (Bug #6387 [<http://bugs.mysql.com/6387>])
- InnoDB: Fixed a bug in `LOAD DATA INFILE...REPLACE` printing duplicate key error when executing the same load query several times. (Bug #5835 [<http://bugs.mysql.com/5835>])
- InnoDB: Refuse to open new-style tables created with MySQL 5.0.3 or later. (Bug #7089 [<http://bugs.mysql.com/7089>])
- InnoDB: Do not call `rewind()` when displaying `SHOW INNODB STATUS` information on `stderr`.
- InnoDB: If one used `INSERT IGNORE` to insert several rows at a time, and the first inserts were ignored because of a duplicate key collision, then InnoDB in a replication slave assigned `AUTO_INCREMENT` values 1 bigger than in the master. This broke the MySQL replication. (Bug #6287 [<http://bugs.mysql.com/6287>])
- InnoDB: Fix two hangs: `FOREIGN KEY` constraints treated table and database names as case-insensitive. `RENAME TABLE t TO T` would hang in an endless loop if `t` had a foreign key constraint defined on it. Fix also a hang over the dictionary mutex that would occur if one tried in `ALTER TABLE` or `RENAME TABLE` to create a foreign key constraint name that collided with another existing name. (Bug #3478 [<http://bugs.mysql.com/3478>])
- InnoDB: Treat character `0xA0` as space in InnoDB's `FOREIGN KEY` parser if MySQL treats it as space in the default charset. EMS MySQL Manager inserts character `0xA0` after the table name in an `ALTER`, which confused InnoDB's parser.
- Fixed a bug which caused a crash when only the slave I/O thread was stopped and restarted. (Bug #6148 [<http://bugs.mysql.com/6148>])
- If a connection had an open transaction but had done no updates to transactional tables (for example if had just done a `SELECT FOR UPDATE` then executed a non-transactional update, that update automatically committed the transaction (thus releasing InnoDB's row-level locks etc). (Bug #5714 [<http://bugs.mysql.com/5714>])
- If a connection was interrupted by a network error and did a rollback, the network error code got stored into the `BEGIN` and `ROLLBACK` binary log events; that caused superfluous slave stops. (Bug #6522 [<http://bugs.mysql.com/6522>])
- A sequence of `BEGIN` (or `SET AUTOCOMMIT=0`), `FLUSH TABLES WITH READ LOCK`, transactional update, `COMMIT`, `FLUSH TABLES WITH READ LOCK` could hang the connection forever and possibly the MySQL server itself. This happened for example when running the `innobackup` script several times. (Bug #6732 [<http://bugs.mysql.com/6732>])

D.3.4. Changes in release 4.0.22 (27 Oct 2004)

Functionality added or changed:

- The `--with-openssl` option for **configure** now accepts a path prefix as an argument. `--with-openssl-includes` and `--with-openssl-libs` are still supported, but are needed only to override the default values. (Bug #5494 [<http://bugs.mysql.com/5494>])

- Added new `--without-man` option to **configure** to suppress building/installing the manual pages. (Bug #5379 [<http://bugs.mysql.com/5379>])
- InnoDB: New **mysqld** option `--innodb-table-locks` and session variable `innodb_table_locks` (on by default). In applications using `AUTOCOMMIT=1` and MySQL's `LOCK TABLES` command, InnoDB's internal table locks that were added in 4.0.20 can cause deadlocks. You can set `innodb_table_locks=0` in `my.cnf` to remove that problem. See Section 15.17, "Restrictions on InnoDB Tables". (Bug #3299 [<http://bugs.mysql.com/3299>], Bug #5998 [<http://bugs.mysql.com/5998>])
- InnoDB: Added the startup option and settable global variable `innodb_max_purge_lag` for delaying `INSERT`, `UPDATE` and `DELETE` operations when the purge operations are lagging. The default value of this parameter is zero, meaning that there are no delays. See Section 15.13, "Implementation of Multi-Versioning".
- InnoDB: Change error code to `HA_ERR_ROW_IS_REFERENCED` if we cannot `DROP` a parent table because it is referenced by a `FOREIGN KEY` constraint.

Bugs fixed:

- Fixed bug in server which caused connection stall when one of deprecated `libmysqlclient` functions `mysql_create_db()`, `mysql_rm_db()` were called and were going to return error. (Bug #6081 [<http://bugs.mysql.com/6081>])
- Fixed returning wrong query result from query cache if a temporary table was hiding a real table after putting results to query cache. (Bug #6084 [<http://bugs.mysql.com/6084>])
- Fixed `ENABLE KEYS`, which failed if `tmpdir` ran out of space. Now, a full repair is done in this case. (Bug #5625 [<http://bugs.mysql.com/5625>])
- Fixed an improper error message when trying to drop a table which is referenced by a `FOREIGN KEY` constraint. (Bug #5784 [<http://bugs.mysql.com/5784>])
- Fixed a bug that allowed `FLUSH TABLE(S)` to close `HANDLER` tables. `HANDLER` tables are now reopened after a `FLUSH TABLE(S)` the next time they are used. However, they lose their file position if this happens. (Bug #4286 [<http://bugs.mysql.com/4286>])
- Fixed a bug that allowed `HANDLER` tables with the same alias to be opened multiple times. `HANDLER` aliases must now be unique, even though it is syntactically correct in versions below 4.1, to qualify them with their base table's database name (e.g. `test_db.handler_tbl`, but this now conflicts with e.g. `another_db.handler_tbl`). (Bug #4335 [<http://bugs.mysql.com/4335>])
- Fixed crash when using MySQL 4.0 with privilege tables from MySQL 5.0.
- **mysqlimport** now reads input files locally from the client host only if the `--local` option is given. Previously, it assumed incorrectly in some cases that files were local even without `-local`. (Bug #5829 [<http://bugs.mysql.com/5829>])
- InnoDB: Make the check for excessive semaphore waits to tolerate glitches in the system clock (do not crash the server if the system time is adjusted while InnoDB is under load.). (Bug #5898 [<http://bugs.mysql.com/5898>])
- InnoDB: Fixed a bug in the InnoDB `FOREIGN KEY` parser that prevented `ALTER TABLE` of tables containing '#' in their names. (Bug #5856 [<http://bugs.mysql.com/5856>])
- InnoDB: Fixed problem introduced in 4.0.21 where a connection starting a transaction, doing updates, then `FLUSH TABLES WITH READ LOCK`, then `COMMIT`, would cause replication slaves to stop (complaining about error 1223). Bug surfaced when using the InnoDB `innobackup` script. (Bug #5949 [<http://bugs.mysql.com/5949>])
- InnoDB: If one updated a column so that its size changed, or updated it to an externally stored (`TEXT` or `BLOB`) value, then `ANOTHER` externally stored column would show up as 512 bytes

of good data + 20 bytes of garbage in a consistent read that fetched the old version of the row. (Bug #5960 [<http://bugs.mysql.com/5960>])

- InnoDB: Release the dictionary latch during a long cascaded FOREIGN KEY operation, so that we do not starve other users doing CREATE TABLE or other DDL operations. This caused a notorious 'Long semaphore wait' message to be printed to the .err log. (Bug #5961 [<http://bugs.mysql.com/5961>])
- InnoDB: Let InnoDB remember row locking type (X or S) inside LOCK TABLES, also over plain consistent read SELECTs.
- InnoDB: Fixed a bug introduced in 4.0.21. An assertion failed if one used **mysqldump** with the option `-l` or `--opt`, or if one used `LOCK TABLES ... LOCAL`. (Workaround in 4.0.21: use `--quick` and `--single-transaction`. (Bug #5538 [<http://bugs.mysql.com/5538>])
- InnoDB: Having a column prefix index in the primary key, and the same column fully in a secondary key could cause an assertion failure in `row_build_row_ref()`. (Bug #5180 [<http://bugs.mysql.com/5180>])
- Fixed a bug which resulted in an erroneously calculated number of examined rows in UNIONS. This value is printed in the slow query log. (Bug #5879 [<http://bugs.mysql.com/5879>])
- Fixed bug with crash of server on some values of `read_rnd_buffer_size` (Bug #5492 [<http://bugs.mysql.com/5492>])
- Fixed bug which caused truncation of values read from or into `TIMESTAMP` fields if `--new-mode` was enabled. (Bug #4131 [<http://bugs.mysql.com/4131>])
- **mysqladmin** now returns a status of 0 even when the server denies access; such an error means the server is running. (Bug #3120 [<http://bugs.mysql.com/3120>])
- Fixed that if the slave SQL thread found a syntax error in a query (which should be rare, as the master parsed it successfully), it stops. (Bug #5711 [<http://bugs.mysql.com/5711>])
- Fixed that if a write to a MyISAM table fails because of a full disk or an exceeded disk quota, it prints a message to the error log every 10 minutes, and waits until disk becomes free. (Bug #3248 [<http://bugs.mysql.com/3248>])
- Fixed problem with symlinked databases on Windows being shown with `SHOW DATABASES` even if the database name doesn't match the given wildcard (Bug #5539 [<http://bugs.mysql.com/5539>])

D.3.5. Changes in release 4.0.21 (06 Sep 2004)

Functionality added or changed:

- Print `version_comment` (from `./configure --comment` during compilation) when starting the server. E.g.: `Version: '4.0.21-debug' socket: '/tmp/mysql.sock' port: 0 Official MySQL Binary`
- Made the MySQL server not react to signals `SIGHUP` and `SIGQUIT` on Mac OS X 10.3. This is needed because under this OS, the MySQL server receives lots of these signals (reported as Bug #2030 [<http://bugs.mysql.com/2030>]).
- On Windows, the **mysqld-nt** and **mysqld-max-nt** servers now write error messages to the Windows event log in addition to the MySQL error log.

Bugs fixed:

- Fixed an old bug in concurrent accesses to MERGE tables (even one MERGE table and MyISAM tables), that could've resulted in a crash or hang of the server. (Bug #2408 [<http://bugs.mysql.com/2408>], CAN-2004-0837 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0837>])
- Fixed a bug that caused incorrect results from GROUP BY queries with expression in HAVING clause that refers to a BLOB (TEXT, TINYBLOB, etc) fields. (Bug #4358 [<http://bugs.mysql.com/4358>])
- Fixed a bug when memory was not released when HEAP table is dropped. It could only happen on Windows when a symlink file (.sym) is used and if that symlink file contained double backslashes (\\). (Bug #4973 [<http://bugs.mysql.com/4973>])
- Fixed a bug which prevented TIMESTAMP(19) fields from being created. (Bug #4491 [<http://bugs.mysql.com/4491>])
- Fixed a bug that caused wrong results in queries that were using index to search for NULL values in BLOB (TINYBLOB, TEXT, TINYTEXT, etc) columns of MyISAM tables. (Bug #4816 [<http://bugs.mysql.com/4816>])
- Fixed a bug in the function ROUND() reporting incorrect metadata (number of digits after the decimal point). It can be seen, for example, in CREATE TABLE t1 SELECT ROUND(1, 34) . (Bug #4393 [<http://bugs.mysql.com/4393>])
- Fixed precision loss bug in some mathematical functions such as SQRT() and LOG() . (Bug #4356 [<http://bugs.mysql.com/4356>])
- Fixed a long-standing problem with LOAD DATA with the LOCAL option. The problem occurs when an error happens during the LOAD DATA operation. Previously, the connection was broken. Now the error message is returned and connection stays open.
- Optimizer now treats col IN (val) the same way it does for col = val.
- Fixed a problem with net_buffer_length when building the DBD:mysql Perl module. (Bug #4206 [<http://bugs.mysql.com/4206>])
- lower_case_table_names=2 (keep case for table names) was not honored with ALTER TABLE and CREATE/DROP INDEX. (Bug #3109 [<http://bugs.mysql.com/3109>])
- Fixed a crash on declaration of DECIMAL(0,...) column. (Bug #4046 [<http://bugs.mysql.com/4046>])
- Fixed a bug in IF() function incorrectly determining the result type if aggregate functions were involved. (Bug #3987 [<http://bugs.mysql.com/3987>])
- Fixed bug in privilege checking where, under some conditions, one was able to grant privileges on the database, he has no privileges on. (Bug #3933 [<http://bugs.mysql.com/3933>])
- Fixed crash in MATCH ... AGAINST() on a phrase search operator with a missing closing double quote. (Bug #3870 [<http://bugs.mysql.com/3870>], CAN-2004-0956 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0956>])
- Fixed a bug with truncation of big values (> 4294967295) of 64-bit system variables. (Bug #3754 [<http://bugs.mysql.com/3754>])
- If server-id was not set using startup options but with SET GLOBAL, the replication slave still complained that it was not set. (Bug #3829 [<http://bugs.mysql.com/3829>])
- Fixed potential memory overrun in mysql_real_connect() (which required a compromised DNS server and certain operating systems). (Bug #4017 [<http://bugs.mysql.com/4017>], CAN-2004-0836 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0836>])
- During the installation process of the server RPM on Linux, **mysqld** was run as the root system user, and if you had --log-bin=<somewhere_out_of_var_lib_mysql> it cre-

ated binary log files owned by `root` in this directory, which remained owned by `root` after the installation. This is now fixed by starting `mysqld` as the `mysql` system user instead. (Bug #4038 [<http://bugs.mysql.com/4038>])

- Made `DROP DATABASE` honor the value of `lower_case_table_names`. (Bug #4066 [<http://bugs.mysql.com/4066>])
- The slave SQL thread refused to replicate `INSERT ... SELECT` if it examined more than 4 billion rows. (Bug #3871 [<http://bugs.mysql.com/3871>])
- Fixed incorrect destruction of expression which led to crash of server on complex `AND/OR` expressions if query was ignored (either by a replication server because of `-replicate-*-table` rules, or by any MySQL server because of a syntax error). (Bug #3969 [<http://bugs.mysql.com/3969>], Bug #4494 [<http://bugs.mysql.com/4494>])
- Fixed that `mysqlbinlog --position --read-from-remote-server` had wrong `#` at lines. (Bug #4506 [<http://bugs.mysql.com/4506>])
- If `CREATE TEMPORARY TABLE t SELECT` failed while loading the data, the temporary table was not dropped. (Bug #4551 [<http://bugs.mysql.com/4551>])
- Fixed that when a multiple-table `DROP TABLE` failed to drop a table on the master server, the error code was not written to the binary log. (Bug #4553 [<http://bugs.mysql.com/4553>])
- When the slave SQL thread was replicating a `LOAD DATA INFILE` statement, it didn't show the statement in the output of `SHOW PROCESSLIST`. (Bug #4326 [<http://bugs.mysql.com/4326>])
- Fixed that `CREATE TABLE ... TYPE=HEAP ... AS SELECT...` caused replication slave to stop. (Bug #4971 [<http://bugs.mysql.com/4971>])
- Fixed that `disable-local-infile` option had no effect if client read it from a configuration file using `mysql_options(...,MYSQL_READ_DEFAULT,...)`. (Bug #5073 [<http://bugs.mysql.com/5073>])
- Fixed that `mysql-test-run` failed on the `rpl_trunc_binlog` test if running test from the installed (the target of 'make install') directory. (Bug #5050)
- Fixed an unlikely deadlock which could happen when using `KILL`. (Bug #4810)
- Fixed a crash when one connection got `KILLED` while it was doing `START SLAVE`. (Bug #4827 [<http://bugs.mysql.com/4827>])
- Made `FLUSH TABLES WITH READ LOCK` block `COMMIT` if server is running with binary logging; this ensures that the binary log position is trustable when doing a full backup of tables and the binary log. (Bug #4953 [<http://bugs.mysql.com/4953>])
- Fixed that the counter of an `auto_increment` column was not reset by `TRUNCATE TABLE` is the table was a temporary one. (Bug #5033 [<http://bugs.mysql.com/5033>])
- Made database names to compare case-insensitively in fully qualified column names (`database.table.column`) when `lower_case_table_names=1`. (Bug #4792 [<http://bugs.mysql.com/4792>])
- Fixed that `SET CHARACTER SET` was not replicated correctly. MySQL 4.1 does not have that bug. (Bug #4500 [<http://bugs.mysql.com/4500>])

D.3.6. Changes in release 4.0.20 (17 May 2004)

Note: The windows packages had to be repackaged and re-released several times to resolve packaging issues (such as missing files). This did not affect the binaries included (they have not been recompiled), therefore the installation packages are of version 4.0.20d, while the binaries included still

identify themselves as version 4.0.20b.

Functionality added or changed:

- From the Windows distribution, predefined accounts without passwords for remote users ("root@", "@%") were removed (other distributions never had them).
- Phrase search in `MATCH ... AGAINST (... IN BOOLEAN MODE)` no longer matches partial words.

Bugs fixed:

- A crashing bug (race condition) was fixed in InnoDB diagnostic logging. It was introduced in 4.0.19. (Bug #3596 [<http://bugs.mysql.com/3596>])
- Fixed a bug in division / reporting incorrect metadata (number of digits after the decimal point). It can be seen, for example, in `CREATE TABLE t1 SELECT "0.01"/"3"`. (Bug #3612 [<http://bugs.mysql.com/3612>])
- Fixed a problem with non-working `DROP DATABASE` on some configurations (in particular, Linux 2.6.5 with ext3 are known to expose this bug). (Bug #3594 [<http://bugs.mysql.com/3594>])
- Fixed a symlink vulnerability in the `mysqlhotcopy` script. (CAN-2004-0457 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0457>])
- Fixed that in some replication error messages, a very long query caused the rest of the message to be invisible (truncated), by putting the query last in the message. (Bug #3357 [<http://bugs.mysql.com/3357>])

D.3.7. Changes in release 4.0.19 (04 May 2004)

Note: The MySQL 4.0.19 binaries were uploaded to the download mirrors on May, 10th. However, a potential crashing bug was found just before the 4.0.19 release was publicly announced and published from the 4.0 download pages at <http://dev.mysql.com/>.

A fix for the bug was pushed into the MySQL source tree shortly after it could be reproduced and is included in MySQL 4.0.20. Users upgrading from MySQL 4.0.18 should upgrade directly to MySQL 4.0.20 or later.

See (Bug #3596 [<http://bugs.mysql.com/3596>]) for details (it was reported against MySQL-4.1, but was confirmed to affect 4.0.19 as well).

Functionality added or changed:

- If length of a timestamp field is defined as 19, the timestamp is displayed as "YYYY-MM-DD HH:MM:SS". This is done to make it easier to use tables created in MySQL 4.1 to be used in MySQL 4.0.
- If you use `RAID_CHUNKS` with a value > 255 it is set to 255. This was made to ensure that all raid directories are always 2 hex bytes. (Bug #3182 [<http://bugs.mysql.com/3182>])
- Changed that the optimizer now considers the index specified in `FORCE INDEX` clause as a candidate to resolve `ORDER BY` as well.
- The `--log-warnings` server option now is enabled by default. Disable with `--skip-log-warnings`.
- Until now, in `SELECT ... UNION SELECT ... ORDER BY ...`, it was possible to qualify a column name in the `ORDER BY` clause with a table name. This is no longer possible.

Column names in `ORDER BY` should refer to names established in the first `SELECT` of the `UNION`. (Bug #3064 [<http://bugs.mysql.com/3064>])

- Added `max_insert_delayed_threads` system variable as a synonym for `max_delayed_threads`.
- Added `query_cache_wlock_invalidate` system variable. It allows emulation of MyISAM table write-locking behavior, even for queries in the query cache. (Bug #2693 [<http://bugs.mysql.com/2693>])
- The keyword `MASTER_SERVER_ID` is not reserved anymore.
- The following is relevant mainly for Mac OS X users who use a case-insensitive filesystem. This is not relevant for Windows users as InnoDB in this case always stores filenames in lower case:

You can now force `lower_case_table_names` to 0 from the command line or a configuration file. This is useful with case-insensitive filesystems when you have previously not used `lower_case_table_names=1` or `lower_case_table_names=2` and you have created InnoDB tables. With `lower_case_table_names=0`, InnoDB tables were stored in mixed case while setting `lower_case_table_names` to a non-zero value now forces it to lower case (to make the table names case insensitive).

Because it's possible to crash MyISAM tables by referring to them with different case on a case-insensitive filesystem, we recommend that you use `lower_case_table_names` or `lower_case_table_names=2` on such filesystems.

The easiest way to convert to use `lower_case_table_names=2` is to dump all your InnoDB tables with **mysqldump**, drop them and then restore them.

- Changed that the relay log is flushed to disk by the slave I/O thread every time it reads a relay log event. This reduces the risk of losing some part of the relay log in case of brutal crash.
- When a session having open temporary tables terminates, the statement automatically written to the binary log is now `DROP TEMPORARY TABLE IF EXISTS` instead of `DROP TEMPORARY TABLE`, for more robustness.
- Added option `--replicate-same-server-id`.

Bugs fixed:

- Added missing full-text variable `ft_stopword_file` to **myisamchk**.
- Don't allow stray `' , '` at the end of field specifications. (Bug #3481 [<http://bugs.mysql.com/3481>])
- `INTERVAL` now can handle big values for seconds, minutes and hours. (Bug #3498 [<http://bugs.mysql.com/3498>])
- Blank hostname did not work as documented for table and column privileges. Now it works the same way as `' % '`. (Bug #3473 [<http://bugs.mysql.com/3473>])
- Fixed a harmless buffer overflow in `replace` utility. (Bug# 3541)
- Fixed `SOUNDEX()` to ignore non-alphabetic characters also in the beginning of the string. (Bug #3556 [<http://bugs.mysql.com/3556>])
- Fixed a bug in `MATCH ... AGAINST()` searches when another thread was doing concurrent inserts into the MyISAM table in question. The first --- full-text search --- query could return incorrect results in this case (for example, ``phantom" rows or not all matching rows, even an empty result set). The easiest way to check whether you are affected is to start **mysqld** with `--skip-concurrent-insert` switch and see if it helps.

- Fixed bug when doing `DROP DATABASE` on a directory containing non-MySQL files. Now a proper error message is returned.
- Fixed bug in `ANALYZE TABLE` on a BDB table inside a transaction that hangs server thread. (Bug #2342 [<http://bugs.mysql.com/2342>])
- Fixed a symlink vulnerability in the `mysqlbug` script. (Bug #3284 [<http://bugs.mysql.com/3284>], CAN-2004-0381 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0381>])
- Fixed core dump bug in `SELECT DISTINCT` where all selected parts were constants and there were hidden columns in the created temporary table. (Bug #3203 [<http://bugs.mysql.com/3203>])
- Fixed core dump bug in `COUNT(DISTINCT)` when there was a lot of values and one had a big value for `max_heap_table_size`.
- Fixed problem with multiple-table-update and BDB tables. (Bug: #3098)
- Fixed memory leak when dropping database with RAID tables. (Bug #2882 [<http://bugs.mysql.com/2882>])
- Fixed core dump crash in replication during relay-log switch when the relay log went over `max_relay_log_size` and the slave thread did a `flush_io_cache()` at the same time.
- Fixed hangup bug when issuing multiple `SLAVE START` from different threads at the same time. (Bug #2921 [<http://bugs.mysql.com/2921>])
- Fixed bug when using `DROP DATABASE` with `lower_case_table_names=2`.
- Fixed wrong result in `UNION` when using `lower_case_table_names=2`. (Bug #2858 [<http://bugs.mysql.com/2858>])
- One can now kill threads that is 'stuck' in the join optimizer (can happen when there is MANY tables in the join in which case the optimizer can take really long time). (Bug #2825 [<http://bugs.mysql.com/2825>])
- Rollback `DELETE` and `UPDATE` statements if thread is killed. (Bug #2422 [<http://bugs.mysql.com/2422>])
- Ensure that all rows in an `INSERT DELAYED` statement is written at once if binary logging is enabled. (Bug #2491 [<http://bugs.mysql.com/2491>]).
- Fixed bug in query cache statistic, more accurate formula linked statistic variables mentioned in the manual.
- Fixed a bug in parallel repair (**myisamchk -p**, `myisam_repair_threads`) - sometimes repair process failed to repair a table. (Bug #1334 [<http://bugs.mysql.com/1334>])
- Fixed bugs with names of tables, databases and columns that end to space (Bug #2985 [<http://bugs.mysql.com/2985>])
- Fixed a bug in multiple-table `UPDATE` statements involving at least one constant table. Bug was exhibited in allowing non matching row to be updated. (Bug #2996 [<http://bugs.mysql.com/2996>]).
- Fixed all bugs in scripts for creating/upgrading system database (Bug #2874 [<http://bugs.mysql.com/2874>]) Added tests which guarantee against such bugs in the future.
- Fixed bug in `mysql` command-line client in interpreting quotes within comments. (Bug #539 [<http://bugs.mysql.com/539>])
- `--set-character-set` and `--character-sets-dir` options in **myisamchk** now work.

- Fixed a bug in **mysqlbinlog** that caused one pointer to be free'd twice in some cases.
- Fixed a bug in boolean full-text search, that sometimes could lead to false matches in queries with several levels of subexpressions using + operator (for example, `MATCH ... AGAINST('+(+(word1 word2)) +word3*' IN BOOLEAN MODE)`).
- Fixed Windows-specific portability bugs in `myisam_ftdump`.
- Fixed a bug in multiple-table DELETE that was caused by foreign key constraints. If the order of the tables established by MySQL optimizer did not match parent-child order, no rows were deleted and no error message was provided. (Bug #2799 [<http://bugs.mysql.com/2799>])
- Fixed a few years old bug in the range optimizer that caused a segmentation fault on some very rare queries. (Bug #2698 [<http://bugs.mysql.com/2698>])
- Replication: If a client connects to a slave server and issues an administrative statement for a table (for example, `OPTIMIZE TABLE` or `REPAIR TABLE`), this could sometimes stop the slave SQL thread. This does not lead to any corruption, but you must use `START SLAVE` to get replication going again. (Bug #1858 [<http://bugs.mysql.com/1858>]) The bug was accidentally not fixed in 4.0.17 as it was unfortunately earlier said.
- Fixed that when a Rotate event is found by the slave SQL thread in the middle of a transaction, the value of `Relay_Log_Pos` in `SHOW SLAVE STATUS` remains correct. (Bug #3017 [<http://bugs.mysql.com/3017>])
- Corrected the master's binary log position that InnoDB reports when it is doing a crash recovery on a slave server. (Bug #3015 [<http://bugs.mysql.com/3015>])
- Changed that when a `DROP TEMPORARY TABLE` statement is automatically written to the binary log when a session ends, the statement is recorded with an error code of value zero (this ensures that killing a `SELECT` on the master does not result in a superfluous error on the slave). (Bug #3063 [<http://bugs.mysql.com/3063>])
- Changed that when a thread handling `INSERT DELAYED` (also known as a `delayed_insert` thread) is killed, its statements are recorded with an error code of value zero (killing such a thread does not endanger replication, so we thus avoid a superfluous error on the slave). (Bug #3081 [<http://bugs.mysql.com/3081>])
- Fixed deadlock when two `START SLAVE` commands were run at the same time. (Bug #2921 [<http://bugs.mysql.com/2921>])
- Fixed that a statement never triggers a superfluous error on the slave, if it must be excluded given the `--replicate-*` options. The bug was that if the statement had been killed on the master, the slave would stop. (Bug #2983 [<http://bugs.mysql.com/2983>])
- The `--local-load` option of **mysqlbinlog** now requires an argument.
- Fixed a segmentation fault when running `LOAD DATA FROM MASTER` after `RESET SLAVE`. (Bug #2922 [<http://bugs.mysql.com/2922>])
- Fixed a rare error condition that caused the slave SQL thread spuriously to print the message `Binlog has bad magic number` and stop when it was not necessary to do so. (Bug #3401 [<http://bugs.mysql.com/3401>])
- Fixed bug in privilege checking of `ALTER TABLE RENAME`. (Bug #3270 [<http://bugs.mysql.com/3270>], CAN-2004-0835 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0835>])
- Fixed the column `Exec_master_log_pos` (and its disk image in the `relay-log.info` file) to be correct if the master had version 3.23 (it was too big by 6 bytes). This bug does not exist in the 5.0 version. (Bug #3400 [<http://bugs.mysql.com/3400>])
- Fixed that **mysqlbinlog** does not forget to print a `USE` command under rare circumstances where

the binary log contained a `LOAD DATA INFILE` command. (Bug #3415 [<http://bugs.mysql.com/3415>])

- Fixed a memory corruption when replicating a `LOAD DATA INFILE` when the master had version 3.23. Some smaller problems remain in this setup, See Section 6.7, “Replication Features and Known Problems”. (Bug #3422 [<http://bugs.mysql.com/3422>])
- Multiple-table `DELETE` statements were always replicated by the slave if there were some `--replicate-*-ignore-table` options and no `--replicate-*-do-table` options. (Bug #3461 [<http://bugs.mysql.com/3461>])
- Fixed a crash of the MySQL slave server when it was built with `--with-debug` and replicating itself. (Bug #3568 [<http://bugs.mysql.com/3568>])

D.3.8. Changes in release 4.0.18 (12 Feb 2004)

Functionality added or changed:

- Fixed processing of `LOAD DATA` by `mysqlbinlog` in remote mode. (Bug #1378 [<http://bugs.mysql.com/1378>])
- The `ft_dump` utility program was renamed to `myisam_ftdump`, and is included in binary distributions.
- `ENGINE` is now a synonym for the `TYPE` option for `CREATE TABLE` and `ALTER TABLE`.
- `lower_case_table_names` system variable now can take a value of 2, to store table names in mixed case on case-insensitive filesystems. It's forced to 2 if the database directory is located on a case-insensitive filesystem.
- For replication of `MEMORY (HEAP)` tables: Made the master automatically write a `DELETE FROM` statement to its binary log when a `MEMORY` table is opened for the first time since master's startup. This is for the case where the slave has replicated a non-empty `MEMORY` table, then the master is shut down and restarted: the table is now empty on master; the `DELETE FROM` empties it on slave too. Note that even with this fix, between the master's restart and the first use of the table on master, the slave still has out-of-date data in the table. But if you use the `init-file` option to populate the `MEMORY` table on the master at startup, it ensures that the failing time interval is zero. (Bug #2477 [<http://bugs.mysql.com/2477>])
- Optimizer is now better tuned for the case where the first used key part (of many) is a constant. (Bug #1679 [<http://bugs.mysql.com/1679>])
- Removed old non-working `--old-rpl-compat` server option, which was a holdover from the very first 4.0.x versions. (Bug #2428 [<http://bugs.mysql.com/2428>])
- Added option `--sync_frm`. It's on by default, to instruct MySQL to sync to disk each time `.frm` file is created. Use `--disable-sync_frm` to disable.

Bugs fixed:

- `mysqlhotcopy` now works on NetWare.
- `DROP DATABASE` could not drop databases with `RAID` tables that had more than nine `RAID_CHUNKS`. (Bug #2627 [<http://bugs.mysql.com/2627>])
- Fixed bug in range optimizer when using overlapping ranges. (Bug #2448 [<http://bugs.mysql.com/2448>])
- Limit `wait_timeout` to 2147483 on Windows (OS limit). (Bug #2400

[<http://bugs.mysql.com/2400>)]

- Fixed bug when `--init-file` crashes MySQL if it contains a large `SELECT`. (Bug #2526 [<http://bugs.mysql.com/2526>])
- `SHOW KEYS` now shows `NULL` in the `Sub_part` column for `FULLTEXT` indexes.
- The signal thread's stack size was increased to enable **mysqld** to run on Debian/IA-64 with a TLS-enabled `glibc`. (Bug #2599 [<http://bugs.mysql.com/2599>])
- Now only the `SELECT` privilege is needed for tables that are only read in multiple-table `UPDATE` statements. (Bug #2377 [<http://bugs.mysql.com/2377>])
- Give proper error message if one uses `LOCK TABLES ... ; INSERT ... SELECT` and one used the same table in the `INSERT` and `SELECT` part. (Bug #2296 [<http://bugs.mysql.com/2296>])
- `SELECT INTO ... DUMPFILE` now deletes the generated file on error.
- Fixed foreign key reference handling to allow references to column names that contain spaces. (Bug #1725 [<http://bugs.mysql.com/1725>])
- Fixed problem with index reads on character columns with BDB tables. The symptom was that data could be returned in the wrong lettercase. (Bug #2509 [<http://bugs.mysql.com/2509>])
- Fixed a spurious table corruption problem that could sometimes appear on tables with indexed `TEXT` columns if these columns happened to contain values having trailing spaces. This bug was introduced in 4.0.17.
- Fixed a problem where some queries could hang if a condition like `indexed_TEXT_column = expr` was present and the column contained values having trailing spaces. This bug was introduced in 4.0.17.
- Fixed a bug that could cause incorrect results from a query that involved range conditions on indexed `TEXT` columns that happened to contain values having trailing spaces. This bug was introduced in 4.0.17. (Bug #2295 [<http://bugs.mysql.com/2295>])
- Fixed incorrect path names in some of the manual pages. (Bug #2270 [<http://bugs.mysql.com/2270>])
- Fixed spurious ```table corrupted``` errors in parallel repair operations. See Section 5.3.3, "Server System Variables".
- Fixed a crashing bug in parallel repair operations. See Section 5.3.3, "Server System Variables".
- Fixed bug in updating MyISAM tables for BLOB values longer than 16MB. (Bug #2159 [<http://bugs.mysql.com/2159>])
- Fixed bug in **mysqld_safe** when running multiple instances of MySQL. (Bug #2114 [<http://bugs.mysql.com/2114>])
- Fixed a bug in using `HANDLER` statement with tables not from a current database. (Bug #2304 [<http://bugs.mysql.com/2304>])
- Fixed a crashing bug that occurred due to the fact that multiple-table `UPDATE` statements did not check that there was only one table to be updated. (Bug #2103 [<http://bugs.mysql.com/2103>])
- Fixed a crashing bug that occurred due to BLOB column type index size being calculated incorrectly in `MIN()` and `MAX()` optimizations. (Bug #2189 [<http://bugs.mysql.com/2189>])
- Fixed a bug with incorrect syntax for `LOCK TABLES` in **mysqldump**. (Bug #2242 [<http://bugs.mysql.com/2242>])
- Fixed a bug in **mysqld_safe** that caused **mysqld** to generate a warning about duplicate

xxx options if this option was specified in the [mysqld] or [server] sections of my.cnf. (Bug #2163 [<http://bugs.mysql.com/2163>])

- INSERT DELAYED . . . SELECT . . . could cause table corruption because tables were not locked properly. This is now fixed by ignoring DELAYED in this context. (Bug #1983 [<http://bugs.mysql.com/1983>])
- Replication: Sometimes the master gets a non-fatal error during the execution of a statement that does not immediately succeed. (For example, a write to a MyISAM table may first receive "no space left on device," but later complete when disk space becomes available. See Section A.4.3, "How MySQL Handles a Full Disk".) The bug was that the master forgot to reset the error code to 0 after success, so the error code got into its binary log, thus causing the slave to issue false alarms such as "did not get the same error as on master." (Bug #2083 [<http://bugs.mysql.com/2083>])
- Removed a misleading "check permissions on master.info" from a replication error message, because the cause of the problem could be something other than permissions. (Bug #2121 [<http://bugs.mysql.com/2121>])
- Fixed a crash when the replication slave was unable to create the first relay log. (Bug #2145 [<http://bugs.mysql.com/2145>])
- Replication of LOAD DATA INFILE for an empty file from a 3.23 master to a 4.0 slave caused the slave to print an error. (Bug #2452 [<http://bugs.mysql.com/2452>])
- When automatically forcing lower_case_table_names to 1 if the file system was case insensitive, **mysqld** could crash. This bug existed only in MySQL 4.0.17. (Bug #2481 [<http://bugs.mysql.com/2481>])
- Restored ability to specify default values for TIMESTAMP columns that was erroneously disabled in previous release. (Bug #2539 [<http://bugs.mysql.com/2539>]) Fixed SHOW CREATE TABLE to reflect these values. (Bug #1885 [<http://bugs.mysql.com/1885>]) Note that because of the auto-update feature for the first TIMESTAMP column in a table, it makes no sense to specify a default value for the column. Any such default is silently ignored (unless another TIMESTAMP column is added before this one). Also fixed the meaning of the DEFAULT keyword when it is used to specify the value to be inserted into a TIMESTAMP column other than the first. (Bug #2464 [<http://bugs.mysql.com/2464>])
- Fixed bug for out-of-range arguments on QNX platform that caused UNIX_TIMESTAMP() to produce incorrect results or that caused non-zero values to be inserted into TIMESTAMP columns. (Bug #2523 [<http://bugs.mysql.com/2523>]) Also, current time zone now is taken into account when checking if datetime values satisfy both range boundaries for TIMESTAMP columns. The range allowed for a TIMESTAMP column is time zone-dependent and equivalent to a range of 1970-01-01 00:00:01 UTC to 2037-12-31 23:59:59 UTC.
- Multiple-table DELETE statements were never replicated by the slave if there were any --replicate-*-table options. (Bug #2527 [<http://bugs.mysql.com/2527>])
- Changes to session counterparts of variables query_prealloc_size, query_alloc_block_size, trans_prealloc_size, trans_alloc_block_size now have an effect. (Bug #1948 [<http://bugs.mysql.com/1948>])
- Fixed bug in ALTER TABLE RENAME, when rename to the table with the same name in another database silently dropped destination table if it existed. (Bug #2628 [<http://bugs.mysql.com/2628>])

D.3.9. Changes in release 4.0.17 (14 Dec 2003)

Functionality added or changed:

- **mysqldump** no longer dumps data for MERGE tables. (Bug #1846

)

- `lower_case_table_names` is now forced to 1 if the database directory is located on a case-insensitive filesystem. (Bug #1812 [<http://bugs.mysql.com/1812>])
- Symlink creation is now disabled on systems where `realpath()` doesn't work. (Before one could use `CREATE TABLE .. DATA DIRECTORY=..` even if `HAVE_BROKEN_REALPATH` was defined. This is now disabled to avoid problems when running `ALTER TABLE`).
- Inserting a negative `AUTO_INCREMENT` value in a MyISAM table no longer updates the `AUTO_INCREMENT` counter to a big unsigned value. (Bug #1366 [<http://bugs.mysql.com/1366>])
- Added four new modes to `WEEK(..., mode)` function. See `WEEK(date: (mode))`. (Bug #1178 [<http://bugs.mysql.com/1178>])
- Allow `UNION DISTINCT` syntax.
- MySQL now syncs to disk each time `.frm` file is created.
- `mysql_server_init()` now returns 1 if it can't initialize the environment. (Previously `mysql_server_init()` called `exit(1)` if it could not create a key with `pthread_key_create()`. (Bug #2062 [<http://bugs.mysql.com/2062>])
- Allow spaces in Windows service names.
- Changed the default Windows service name for **mysqld** from `MySql` to `MySQL`. This should not affect usage, because service names are not case sensitive.
- When you install **mysqld** as a service on Windows systems, **mysqld** reads startup options in option files from the option group with the same name as the service name. (Except when the service name is `MySQL`).

Bugs fixed:

- Sending `SIGHUP` to **mysqld** crashed the server if it was running with `--log-bin`. (Bug #2045 [<http://bugs.mysql.com/2045>])
- One can now configure MySQL as a Windows service as a normal user. (Bug #1802 [<http://bugs.mysql.com/1802>]). Thanks to Richard Hansen for fixing this.
- Database names are now compared in lowercase in `ON` clauses when `lower_case_table_names` is set. (Bug #1736 [<http://bugs.mysql.com/1736>])
- `IGNORE ... LINES` option to `LOAD DATA INFILE` didn't work when used with fixed length rows. (Bug #1704 [<http://bugs.mysql.com/1704>])
- Fixed problem with `UNIX_TIMESTAMP()` for timestamps close to 0. (Bug #1998 [<http://bugs.mysql.com/1998>])
- Fixed problem with character values greater than 128 in the `QUOTE()` function. (Bug #1868 [<http://bugs.mysql.com/1868>])
- Fixed searching of `TEXT` with `endspace`. (Bug #1651 [<http://bugs.mysql.com/1651>])
- Fixed caching bug in multiple-table updates where same table was used twice. (Bug #1711 [<http://bugs.mysql.com/1711>])
- Fixed directory permissions for the MySQL-server RPM documentation directory. (Bug #1672 [<http://bugs.mysql.com/1672>])

- Fixed server crash when updating an ENUM column that is set to the empty string (for example, with REPLACE ()). (Bug #2023 [<http://bugs.mysql.com/2023>])
- **mysql** client program now correctly prints connection identifier returned by mysql_thread_id() as unsigned integer rather than as signed integer. (Bug #1951 [<http://bugs.mysql.com/1951>])
- FOUND_ROWS() could return incorrect number of rows after a query with an impossible WHERE condition. (Bug #1468 [<http://bugs.mysql.com/1468>])
- SHOW DATABASES no longer shows .sym files (on Windows) that do not point to a valid directory. (Bug #1385 [<http://bugs.mysql.com/1385>])
- Fixed a possible memory leak on Mac OS X when using the shared libmysql.so library. (from pthread_key_create()). (Bug #2061 [<http://bugs.mysql.com/2061>])
- Fixed bug in UNION statement with alias *. (Bug #1249 [<http://bugs.mysql.com/1249>])
- Fixed a bug in DELETE ... ORDER BY ... LIMIT where the rows were not deleted in the proper order. (Bug #1024 [<http://bugs.mysql.com/1024>], Bug #1697 [<http://bugs.mysql.com/1697>]).
- Fixed serious problem with multi-threaded programs on Windows that used the embedded MySQL libraries. (Locks of tables were not handled correctly between different threads).
- Code cleanup: Fixed a few code defects (potential memory leaks, null pointer dereferences, uninitialized variables). Thanks to Reasoning Inc. for informing us about these findings.
- Fixed a buffer overflow error that occurred with prepended '0' characters in some columns of type DECIMAL. (Bug #2128 [<http://bugs.mysql.com/2128>])
- Filesort was never shown in EXPLAIN if query contained an ORDER BY NULL clause. (Bug #1335 [<http://bugs.mysql.com/1335>])
- Fixed invalidation of whole query cache on DROP DATABASE. (Bug #1898 [<http://bugs.mysql.com/1898>])
- Fixed bug in range optimizer that caused wrong results for some unlikely AND/OR queries. (Bug #1828 [<http://bugs.mysql.com/1828>])
- Fixed a crash in ORDER BY when ordering by expression and identifier. (Bug #1945 [<http://bugs.mysql.com/1945>])
- Fixed a crash in an open HANDLER when an ALTER TABLE was executed in a different connection. (Bug #1826 [<http://bugs.mysql.com/1826>])
- Fixed a bug in trunc* operator of full-text search which sometimes caused MySQL not to find all matched rows.
- Fixed bug in prepending '0' characters to DECIMAL column values.
- Fixed optimizer bug, introduced in 4.0.16, when REF access plan was preferred to more efficient RANGE on another column.
- Fixed problem when installing a MySQL server as a Windows service using a command of the form **mysqld --install mysql --defaults-file=***path-to-file*. (Bug #1643 [<http://bugs.mysql.com/1643>])
- Fixed an incorrect result from a query that uses only const tables (such as one-row tables) and non-constant expression (such as RAND()). (Bug #1271 [<http://bugs.mysql.com/1271>])
- Fixed bug when the optimizer did not take SQL_CALC_FOUND_ROWS into account if LIMIT clause was present. (Bug #1274 [<http://bugs.mysql.com/1274>])

- **mysqlbinlog** now asks for a password at the console when the `-p` or `--password` option is used with no argument. This is consistent with the way that other clients such **mysqladmin** and **mysqldump** behave. **Note:** A consequence of this change is that it is no longer possible to invoke **mysqlbinlog** as **mysqlbinlog -p pass_val** (with a space between the `-p` option and the following password value). (Bug #1595 [<http://bugs.mysql.com/1595>])
- Fixed bug accidentally introduced in 4.0.16 where the slave SQL thread deleted its replicated temporary tables when `STOP SLAVE` was issued.
- In a ``chain" replication setup A->B->C, if 2 sessions on A updated temporary tables of the same name at the same time, the binary log of B became incorrect, resulting in C becoming confused. (Bug #1686 [<http://bugs.mysql.com/1686>])
- In a ``chain" replication setup A->B->C, if `STOP SLAVE` was issued on B while it was replicating a temporary table from A, then when `START SLAVE` was issued on B, the binary log of B became incorrect, resulting in C becoming confused. (Bug #1240 [<http://bugs.mysql.com/1240>])
- When `MASTER_LOG_FILE` and `MASTER_LOG_POS` were not specified, `CHANGE MASTER` used the coordinates of the slave I/O thread to set up replication, which broke replication if the slave SQL thread lagged behind the slave I/O thread. This caused the slave SQL thread to lose some events. The new behavior is to use the coordinates of the slave SQL thread instead. See Section 13.6.2.1, "CHANGE MASTER TO Syntax". (Bug #1870 [<http://bugs.mysql.com/1870>])
- Now if integer is stored or converted to `TIMESTAMP` or `DATETIME` value checks of year, month, day, hour, minute and second ranges are performed and numbers representing illegal timestamps are converted to 0 value. This behavior is consistent with manual and with behavior of string to `TIMESTAMP/DATETIME` conversion. (Bug #1448 [<http://bugs.mysql.com/1448>])
- Fixed bug when `BIT_AND()` and `BIT_OR()` group functions returned incorrect value if `SELECT` used a temporary table and no rows were found. (Bug #1790 [<http://bugs.mysql.com/1790>]).
- `BIT_AND()` is now unsigned in all contexts. This means that it now returns 18446744073709551615 (= 0xffffffffffffffff) instead of -1 if there were no rows in the result.
- Fixed bug with `BIT_AND()` still returning signed value for an empty set in some cases. (Bug #1972 [<http://bugs.mysql.com/1972>])
- Fixed bug with `^ (XOR)` and `>>` (bit shift) still returning signed value in some cases. (Bug #1993 [<http://bugs.mysql.com/1993>])
- Replication: a rare race condition in the slave SQL thread, which could lead to a wrong complain that the relay log is corrupted. (Bug #2011 [<http://bugs.mysql.com/2011>])
- Replication: in the slave SQL thread, a multiple-table `UPDATE` could produce a wrong complain that some record was not found in one table, if the `UPDATE` was preceded by a `INSERT . . . SELECT`. (Bug #1701 [<http://bugs.mysql.com/1701>])
- Fixed deficiency in MySQL code which is responsible for scanning directories. This deficiency caused `SHOW TABLE STATUS` to be very slow when a database contained a large number of tables, even if a single particular table were specified. (Bug #1952 [<http://bugs.mysql.com/1952>])

D.3.10. Changes in release 4.0.16 (17 Oct 2003)

Functionality added or changed:

- Option values in option files now may be quoted. This is useful for values that contain whitespace or comment characters.
- Write memory allocation information to error log when doing **mysqladmin debug**. This works

only on systems that support the `mallinfo()` call (like newer Linux systems).

- Added the following new system variables to allow more precise memory allocation: `range_alloc_block_size`, `query_alloc_block_size`, `query_prealloc_size`, `transaction_alloc_block_size`, and `transaction_prealloc_size`.
- **mysqlbinlog** now reads option files. To make this work, you must now specify `--read-from-remote-server` when reading binary logs from a MySQL server. (Note that using a remote server is deprecated and may disappear in future **mysqlbinlog** versions).
- Block SIGPIPE signals also for non-threaded programs. The blocking is moved from `mysql_init()` to `mysql_server_init()`, which is automatically called on the first call to `mysql_init()`.
- Added `--libs_r` and `--include` options to **mysql_config**.
- New ``>` prompt for **mysql**. This prompt is similar to the `'>` and `">` prompts, but indicates that an identifier quoted with backticks was begun on an earlier line and the closing backtick has not yet been seen.
- Updated **mysql_install_db** to be able to use the local machine's IP address instead of the host-name when building the initial grant tables if `skip-name-resolve` has been specified. This option can be helpful on FreeBSD to avoid thread-safety problems with the FreeBSD resolver libraries. (Thanks to Jeremy Zawodny for the patch.)
- A documentation change: Added a note that when backing up a slave, it is necessary also to back up the `master.info` and `relay-log.info` files, as well as any `SQL_LOAD-*` files located in the directory specified by the `--slave-load-tmpdir` option. All these files are needed when the slave resumes replication after you restore the slave's data.

Bugs fixed:

- Fixed a spurious error `ERROR 14: Can't change size of file (Errcode: 2)` on Windows in `DELETE FROM tbl_name` without a `WHERE` clause or `TRUNCATE TABLE tbl_name`, when `tbl_name` is a MyISAM table. (Bug #1397 [<http://bugs.mysql.com/1397>])
- Fixed a bug that resulted in `thr_alarm queue is full` warnings after increasing the `max_connections` variable with `SET GLOBAL`. (Bug #1435 [<http://bugs.mysql.com/1435>])
- Made `LOCK TABLES` to work when `Lock_tables_priv` is granted on the database level and `Select_priv` is granted on the table level.
- Fixed crash of `FLUSH QUERY CACHE` on queries that use same table several times (Bug #988 [<http://bugs.mysql.com/988>]).
- Fixed core dump bug when setting an enum system variable (such as `SQL_WARNINGS`) to `NULL`.
- Extended the default timeout value for Windows clients from 30 seconds to 1 year. (The timeout that was added in MySQL 4.0.15 was way too short). This fixes a bug that caused `ERROR 2013: Lost connection to MySQL server during query` for queries that lasted longer than 30 seconds, if the client didn't specify a limit with `mysql_options()`. Users of 4.0.15 on Windows should upgrade to avoid this problem.
- More "out of memory" checking in range optimizer.
- Fixed and documented a problem when setting and using a user variable within the same `SELECT` statement. (Bug #1194 [<http://bugs.mysql.com/1194>]).
- Fixed bug in overrun check for BLOB values with compressed tables. This was a bug introduced in 4.0.14. It caused MySQL to regard some correct tables containing BLOB values as corrupted.

(Bug #770 [<http://bugs.mysql.com/770>], Bug #1304 [<http://bugs.mysql.com/1304>], and maybe Bug #1295 [<http://bugs.mysql.com/1295>])

- SHOW GRANTS showed USAGE instead of the real column-level privileges when no table-level privileges were given.
- When copying a database from the master, LOAD DATA FROM MASTER dropped the corresponding database on the slave, thus erroneously dropping tables that had no counterpart on the master and tables that may have been excluded from replication using --replicate-*-table rules. Now LOAD DATA FROM MASTER no longer drops the database. Instead, it drops only the tables that have a counterpart on the master and that match the --replicate-*-table rules. --replicate-*-db rules can still be used to include or exclude a database as a whole from LOAD DATA FROM MASTER. A database also is included or excluded as a whole if there are some rules like --replicate-wild-do-table=db1.% or --replicate-wild-ignore-table=db1.%, as is the case for CREATE DATABASE and DROP DATABASE in replication. (Bug #1248)
- Fixed a bug where **mysqlbinlog** crashed with a segmentation fault when used with the -h or --host option. (Bug #1258 [<http://bugs.mysql.com/1258>])
- Fixed a bug where **mysqlbinlog** crashed with a segmentation fault when used on a binary log containing only final events for LOAD DATA. (Bug #1340 [<http://bugs.mysql.com/1340>])
- **mysqlbinlog** does not reuse temporary filenames from previous runs. Previously **mysqlbinlog** failed if was used several times on the same binary log file that contained a LOAD DATA command.
- Fixed compilation problem when compiling with OpenSSL 0.9.7 with disabled old DES support (If OPENSSSL_DISABLE_OLD_DES_SUPPORT option was enabled).
- Fixed a bug when two (or more) MySQL servers were running on the same machine, and they were both slaves, and at least one of them was replicating some LOAD DATA INFILE command from its master. The bug was that one slave MySQL server sometimes deleted the SQL_LOAD-* files (used for replication of LOAD DATA INFILE and located in the slave-load-tmpdir directory, which defaults to tmpdir) belonging to the other slave MySQL server of this machine, if these slaves had the same slave-load-tmpdir directory. When that happened, the other slave could not replicate LOAD DATA INFILE and complained about not being able to open some SQL_LOAD-* file. (Bug #1357 [<http://bugs.mysql.com/1357>])
- If LOAD DATA INFILE failed for a small file, the master forgot to write a marker (a Delete_file event) in its binary log, so the slave could not delete 2 files (SQL_LOAD-*.info and SQL_LOAD-*.data from its tmpdir. (Bug #1391 [<http://bugs.mysql.com/1391>])
- On Windows, the slave forgot to delete a SQL_LOAD-*.info file from tmpdir after successfully replicating a LOAD DATA INFILE command. (Bug #1392 [<http://bugs.mysql.com/1392>])
- When a connection terminates, MySQL writes DROP TEMPORARY TABLE statements to the binary log for all temporary tables which the connection had not explicitly dropped. MySQL forgot to use backticks to quote the database and table names in the statement. (Bug #1345 [<http://bugs.mysql.com/1345>])
- On some 64-bit machines (some HP-UX and Solaris machines), a slave installed with the 64-bit MySQL binary could not connect to its master (it connected to itself instead). (Bug #1256 [<http://bugs.mysql.com/1256>], Bug #1381 [<http://bugs.mysql.com/1381>])
- Code was introduced in MySQL 4.0.15 for the slave to detect that the master had died while writing a transaction to its binary log. This code reported an error in a legal situation: When the slave I/O thread was stopped while copying a transaction to the relay log, the slave SQL thread would later pretend that it found an unfinished transaction. (Bug #1475 [<http://bugs.mysql.com/1475>])

D.3.11. Changes in release 4.0.15 (03 Sep 2003)

IMPORTANT:

If you are using this release on Windows, you should upgrade at least your clients (any program that uses `libmysql.lib`) to 4.0.16 or above. This is because the 4.0.15 release had a bug in the Windows client library that causes Windows clients using the library to die with a `Lost connection to MySQL server during query` error for queries that take more than 30 seconds. This problem is specific to Windows; clients on other platforms are unaffected.

Functionality added or changed:

- **mysqldump** now correctly quotes all identifiers when communicating with the server. This assures that during the dump process, **mysqldump** never sends queries to the server that result in a syntax error. This problem is **not** related to the **mysqldump** program's output, which was not changed. (Bug #1148 [<http://bugs.mysql.com/1148>])
- Change result set metadata information so that `MIN()` and `MAX()` report that they can return `NULL` (this is true because an empty set returns `NULL`). (Bug #324 [<http://bugs.mysql.com/324>])
- Produce an error message on Windows if a second **mysqld** server is started on the same TCP/IP port as a running **mysqld** server.
- The **mysqld** system variables `wait_timeout`, `net_read_timeout`, and `net_write_timeout` now work on Windows. One can now also set timeouts for read and writes in Windows clients with `mysql_options()`.
- Added option `--sql-mode=NO_DIR_IN_CREATE` to make it possible for slaves to ignore `INDEX DIRECTORY` and `DATA DIRECTORY` options given to `CREATE TABLE`. When this is mode is on, `SHOW CREATE TABLE` does not show the given directories.
- `SHOW CREATE TABLE` now shows the `INDEX DIRECTORY` and `DATA DIRECTORY` options, if they were specified when the table was created.
- The `open_files_limit` system variable now shows the real open files limit.
- `MATCH ... AGAINST()` in natural language mode now treats words that are present in more than 2,000,000 rows as stopwords.
- The Mac OS X installation disk images now include an additional `MySQLStartupItem.pkg` package that enables the automatic startup of MySQL on system startup. See Section 2.5, "Installing MySQL on Mac OS X".
- Most of the documentation included in the binary tarball distributions (`.tar.gz`) has been moved into a subdirectory `docs`. See Section 2.1.5, "Installation Layouts".
- The manual is now included as an additional `info` file in the binary distributions. (Bug #1019 [<http://bugs.mysql.com/1019>])
- The binary distributions now include the embedded server library (`libmysqld.a`) by default. Due to a linking problem with non-gcc compilers, it was not included in all packages of the initial 4.0.15 release. The affected packages were rebuilt and released as 4.0.15a. See Section 1.5.1.2, "The Embedded MySQL Server".
- MySQL can now use range optimization for `BETWEEN` with non-constant limits. (Bug #991 [<http://bugs.mysql.com/991>])
- Replication error messages now include the default database, so that users can check which database the failing query was run for.
- A documentation change: Added a paragraph about how the `binlog-do-db` and `binlog-ignore-db` options are tested against the database on the master (see Section 5.10.4, "The Binary Log"), and a paragraph about how `--replicate-do-db`, `-`

`-replicate-do-table` and analogous options are tested against the database and tables on the slave (see Section 6.8, “Replication Startup Options”).

- Now the slave does not replicate `SET PASSWORD` if it is configured to exclude the `mysql` database from replication (using for example `-replicate-wild-ignore-table=mysql.*`). This was the case for `GRANT` and `REVOKE` since version 4.0.13 (although there was Bug #980 [<http://bugs.mysql.com/980>] in 4.0.13 & 4.0.14, which has been fixed in 4.0.15).
- Rewrote the information shown in the `State` column of `SHOW PROCESSLIST` for replication threads and for `MASTER_POS_WAIT()` and added the most common states for these threads to the documentation, see Section 6.3, “Replication Implementation Details”.
- Added a test in replication to detect the case where the master died in the middle of writing a transaction to the binary log; such unfinished transactions now trigger an error message on the slave.
- A `GRANT` command that creates an anonymous user (that is, an account with an empty username) no longer requires `FLUSH PRIVILEGES` for the account to be recognized by the server. (Bug #473 [<http://bugs.mysql.com/473>])
- `CHANGE MASTER` now flushes `relay-log.info`. Previously this was deferred to the next run of `START SLAVE`, so if **mysqld** was shutdown on the slave after `CHANGE MASTER` without having run `START SLAVE`, the relay log's name and position were lost. At restart they were reloaded from `relay-log.info`, thus reverting to their old (incorrect) values from before `CHANGE MASTER` and leading to error messages (as the old relay log did not exist any more) and the slave threads refusing to start. (Bug #858 [<http://bugs.mysql.com/858>])

Bugs fixed:

- Fixed buffer overflow in password handling which could potentially be exploited by MySQL users with `ALTER` privilege on the `mysql.user` table to execute random code or to gain shell access with the UID of the **mysqld** process (thanks to Jedi/Sector One for spotting and reporting this bug).
- Fixed server crash on `FORCE INDEX` in a query that contained "Range checked for each record" in the `EXPLAIN` output. (Bug #1172 [<http://bugs.mysql.com/1172>])
- Fixed table/column grant handling: The proper sort order (from most specific to less specific, see Section 5.6.6, “Access Control, Stage 2: Request Verification”) was not honored. (Bug #928 [<http://bugs.mysql.com/928>])
- Fixed rare bug in MyISAM introduced in 4.0.3 where the index file header was not updated directly after an `UPDATE` of split dynamic rows. The symptom was that the table had a corrupted delete-link if **mysqld** was shut down or the table was checked directly after the update.
- Fixed Can't unlock file error when running `myisamchk --sort-index` on Windows. (Bug #1119 [<http://bugs.mysql.com/1119>])
- Fixed possible deadlock when changing `key_buffer_size` while the key cache was actively used. (Bug #1088 [<http://bugs.mysql.com/1088>])
- Fixed overflow bug in MyISAM and ISAM when a row is updated in a table with a large number of columns and at least one `BLOB/TEXT` column.
- Fixed incorrect result when doing `UNION` and `LIMIT #, #` when braces were not used around the `SELECT` parts.
- Fixed incorrect result when doing `UNION` and `ORDER BY .. LIMIT #` when one didn't use braces around the `SELECT` parts.
- Fixed problem with `SELECT SQL_CALC_FOUND_ROWS ... UNION ALL ... LIMIT`

where FOUND_ROWS () returned incorrect number of rows.

- Fixed unlikely stack bug when having a BIG expression of type 1+1-1+1-1... in certain combinations. (Bug #871 [<http://bugs.mysql.com/871>])
- Fixed the bug that sometimes prevented a table with a FULLTEXT index from being marked as "analyzed".
- Fixed MySQL so that the column length (in C API) for the second column in SHOW CREATE TABLE is always larger than the data length. The only known application that was affected by the old behavior was Borland dbExpress, which truncated the output from the command. (Bug #1064 [<http://bugs.mysql.com/1064>])
- Fixed crash in comparisons of strings using the tis620 character set. (Bug #1116 [<http://bugs.mysql.com/1116>])
- Fixed ISAM bug in MAX () optimization.
- **myisamchk --sort-records=N** no longer marks table as crashed if sorting failed because of an inappropriate key. (Bug #892 [<http://bugs.mysql.com/892>])
- Fixed a minor bug in MyISAM compressed table handling that sometimes made it impossible to repair compressed table in "Repair by sort" mode. "Repair with keycache" (**myisamchk -safe-recover**) worked, though. (Bug #1015 [<http://bugs.mysql.com/1015>])
- Fixed bug in propagating the version number to the manual included in the distribution files. (Bug #1020 [<http://bugs.mysql.com/1020>])
- Fixed key sorting problem (a PRIMARY key declared for a column that is not explicitly marked NOT NULL was sorted after a UNIQUE key for a NOT NULL column).
- Fixed the result of INTERVAL when applied to a DATE value. (Bug #792 [<http://bugs.mysql.com/792>])
- Fixed compiling of the embedded server library in the RPM spec file. (Bug #959 [<http://bugs.mysql.com/959>])
- Added some missing files to the RPM spec file and fixed some RPM building errors that occurred on Red Hat Linux 9. (Bug #998 [<http://bugs.mysql.com/998>])
- Fixed incorrect XOR evaluation in WHERE clause. (Bug #992 [<http://bugs.mysql.com/992>])
- Fixed bug with processing in query cache merged tables constructed from more than 255 tables. (Bug #930 [<http://bugs.mysql.com/930>])
- Fixed incorrect results from outer join query (for example, LEFT JOIN) when ON condition is always false, and range search is used. (Bug #926 [<http://bugs.mysql.com/926>])
- Fixed a bug causing incorrect results from MATCH ... AGAINST () in some joins. (Bug #942 [<http://bugs.mysql.com/942>])
- MERGE tables do not ignore Using index (from EXPLAIN output) anymore.
- Fixed a bug that prevented an empty table from being marked as "analyzed". (Bug #937 [<http://bugs.mysql.com/937>])
- Fixed **myisamchk --sort-records** crash when used on compressed table.
- Fixed slow (as compared to 3.23) ALTER TABLE and related commands such as CREATE INDEX. (Bug #712 [<http://bugs.mysql.com/712>])
- Fixed segmentation fault resulting from LOAD DATA FROM MASTER when the master was running without the --log-bin option. (Bug #934 [<http://bugs.mysql.com/934>])

- Fixed a security bug: A server compiled without SSL support still allowed connections by users who had the `REQUIRE SSL` option specified for their accounts.
- Fixed a random bug: Sometimes the slave would replicate `GRANT` or `REVOKE` queries even if it was configured to exclude the `mysql` database from replication (for example, using `--replicate-wild-ignore-table=mysql.%`). (Bug #980 [<http://bugs.mysql.com/980>])
- The `Last_Errno` and `Last_Error` fields in the output of `SHOW SLAVE STATUS` are now cleared by `CHANGE MASTER` and when the slave SQL thread starts. (Bug #986 [<http://bugs.mysql.com/986>])
- A documentation mistake: It said that `RESET SLAVE` does not change connection information (master host, port, user, and password), whereas it does. The statement resets these to the startup options (master-host etc) if there were some. (Bug #985 [<http://bugs.mysql.com/985>])
- `SHOW SLAVE STATUS` now shows correct information (master host, port, user, and password) after `RESET SLAVE` (that is, it shows the new values, which are copied from the startup options if there were some). (Bug #985 [<http://bugs.mysql.com/985>])
- Disabled propagation of the original master's log position for events because this caused unexpected values for `Exec_Master_Log_Pos` and problems with `MASTER_POS_WAIT()` in A->B->C replication setup. (Bug #1086 [<http://bugs.mysql.com/1086>])
- Fixed a segfault in `mysqlbinlog` when `--position=x` was used with `x` being between a `Create_file` event and its fellow `Append_block`, `Exec_load` or `Delete_file` events. (Bug #1091 [<http://bugs.mysql.com/1091>])
- `mysqlbinlog` printed superfluous warnings when using `--database`, which caused syntax errors when piped to `mysql`. (Bug #1092 [<http://bugs.mysql.com/1092>])
- Made `mysqlbinlog --database` filter `LOAD DATA INFILE` too (previously, it filtered all queries except `LOAD DATA INFILE`). (Bug #1093 [<http://bugs.mysql.com/1093>])
- `mysqlbinlog` in some cases forgot to put a leading '#' in front of the original `LOAD DATA INFILE` (this command is displayed only for information, not to be run; it is later reworked to `LOAD DATA LOCAL` with a different filename, for execution by `mysql`). (Bug #1096 [<http://bugs.mysql.com/1096>])
- `binlog-do-db` and `binlog-ignore-db` incorrectly filtered `LOAD DATA INFILE` (it was half-written to the binary log). This resulted in a corrupted binary log, which could cause the slave to stop with an error. (Bug #1100 [<http://bugs.mysql.com/1100>])
- When, in a transaction, a transactional table (such as an InnoDB table) was updated, and later in the same transaction a non-transactional table (such as a MyISAM table) was updated using the updated content of the transactional table (with `INSERT ... SELECT` for example), the queries were written to the binary log in an incorrect order. (Bug #873 [<http://bugs.mysql.com/873>])
- When, in a transaction, `INSERT ... SELECT` updated a non-transactional table, and `ROLLBACK` was issued, no error was returned to the client. Now the client is warned that some changes could not be rolled back, as this was the case for normal `INSERT`. (Bug #1113 [<http://bugs.mysql.com/1113>])
- Fixed a potential bug: When `STOP SLAVE` was run while the slave SQL thread was in the middle of a transaction, and then `CHANGE MASTER` was used to point the slave to some non-transactional statement, the slave SQL thread could get confused (because it would still think, from the past, that it was in a transaction).

D.3.12. Changes in release 4.0.14 (18 Jul 2003)

Functionality added or changed:

- Added `default_week_format` system variable. The value is used as the default mode for the `WEEK()` function.
- **mysqld** now reads an additional option file group having a name corresponding to the server's release series: `[mysqld-4.0]` for 4.0.x servers, `[mysqld-4.1]` for 4.1.x servers, and so forth. This allows options to be specified on a series-specific basis.
- The `CONCAT_WS()` function no longer skips empty strings. (Bug #586 [<http://bugs.mysql.com/586>]).
- InnoDB now supports indexing a prefix of a column. This means, in particular, that BLOB and TEXT columns can be indexed in InnoDB tables, which was not possible before.
- A documentation change: Function `INTERVAL(NULL, ...)` returns `-1`.
- Enabled `INSERT` from `SELECT` when the table into which the records are inserted is also a table listed in the `SELECT`.
- Allow `CREATE TABLE` and `INSERT` from any `UNION`.
- The `SQL_CALC_FOUND_ROWS` option now always returns the total number of rows for any `UNION`.
- Removed `--table` option from **mysqlbinlog** to avoid repeating **mysqldump** functionality.
- Comment lines in option files can now start from the middle of a line, too (like `basedir=c:\mysql # installation directory`).
- Changed optimizer slightly to prefer index lookups over full table scans in some boundary cases.
- Added thread-specific `max_seeks_for_key` variable that can be used to force the optimizer to use keys instead of table scans even if the cardinality of the index is low.
- Added optimization that converts `LEFT JOIN` to normal join in some cases.
- A documentation change: added a paragraph about failover in replication (how to use a surviving slave as the new master, how to resume to the original setup). See Section 6.9, "Replication FAQ".
- A documentation change: added warning notes about safe use of the `CHANGE MASTER` command. See Section 13.6.2.1, "CHANGE MASTER TO Syntax".
- MySQL now issues a warning (not an error, as in 4.0.13) when it opens a table that was created with MySQL 4.1.
- Added `--nice` option to **mysqld_safe** to allow setting the niceness of the **mysqld** process. (Thanks to Christian Hammers for providing the initial patch.) (Bug #627 [<http://bugs.mysql.com/627>])
- Added `--read-only` option to cause **mysqld** to allow no updates except from slave threads or from users with the `SUPER` privilege. (Original patch from Markus Benning).
- `SHOW BINLOG EVENTS FROM x` where `x` is less than 4 now silently converts `x` to 4 instead of printing an error. The same change was done for `CHANGE MASTER TO MASTER_LOG_POS=x` and `CHANGE MASTER TO RELAY_LOG_POS=x`.
- **mysqld** now only adds an interrupt handler for the `SIGINT` signal if you start it with the new `-gdb` option. This is because some MySQL users encountered strange problems when they accidentally sent `SIGINT` to **mysqld** threads.
- `RESET SLAVE` now clears the `Last_Errno` and `Last_Error` fields in the output of `SHOW SLAVE STATUS`.
- Added `max_relay_log_size` variable; the relay log is rotated automatically when its size

exceeds `max_relay_log_size`. But if `max_relay_log_size` is 0 (the default), `max_binlog_size` is used (as in older versions). `max_binlog_size` still applies to binary logs in any case.

- `FLUSH LOGS` now rotates relay logs in addition to the other types of logs it rotates.

Bugs fixed:

- Comparison/sorting for `latin1_de` character set was rewritten. The old algorithm could not handle cases like `"sä" > "sa"`. See Section 5.9.1.1, "Using the German Character Set". In rare cases it resulted in table corruption.
- Fixed a problem with the password prompt on Windows. (Bug #683 [<http://bugs.mysql.com/683>])
- `ALTER TABLE ... UNION=(...)` for MERGE table is now allowed even if some underlying MyISAM tables are read-only. (Bug #702 [<http://bugs.mysql.com/702>])
- Fixed a problem with `CREATE TABLE t1 SELECT x'41'`. (Bug #801 [<http://bugs.mysql.com/801>])
- Removed some incorrect lock warnings from the error log.
- Fixed memory overrun when doing `REPAIR TABLE` on a table with a multiple-part `auto_increment` key where one part was a packed CHAR.
- Fixed a probable race condition in the replication code that could potentially lead to INSERT statements not being replicated in the event of a `FLUSH LOGS` command or when the binary log exceeds `max_binlog_size`. (Bug #791 [<http://bugs.mysql.com/791>])
- Fixed a crashing bug in `INTERVAL` and `GROUP BY` or `DISTINCT`. (Bug #807 [<http://bugs.mysql.com/807>])
- Fixed bug in **mysqlhotcopy** so it actually aborts for unsuccessful table copying operations. Fixed another bug so that it succeeds when there are thousands of tables to copy. (Bug #812 [<http://bugs.mysql.com/812>])
- Fixed problem with **mysqlhotcopy** failing to read options from option files. (Bug #808 [<http://bugs.mysql.com/808>])
- Fixed bugs in optimizer that sometimes prevented MySQL from using FULLTEXT indexes even though it was possible (for example, in `SELECT * FROM t1 WHERE MATCH a,b AGAINST("index") > 0`).
- Fixed a bug with `"table is full"` in UNION operations.
- Fixed a security problem that enabled users with no privileges to obtain information on the list of existing databases by using `SHOW TABLES` and similar commands.
- Fixed a stack problem on UnixWare/OpenUnix.
- Fixed a configuration problem on UnixWare/OpenUNIX and OpenServer.
- Fixed a stack overflow problem in password verification. (CAN-2003-0780 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2003-0780>])
- Fixed a problem with `max_user_connections`.
- `HANDLER` without an index now works properly when a table has deleted rows. (Bug #787 [<http://bugs.mysql.com/787>])
- Fixed a bug with `LOAD DATA` in **mysqlbinlog**. (Bug #670 [<http://bugs.mysql.com/670>])

- Fixed that `SET CHARACTER SET DEFAULT` works. (Bug #462 [<http://bugs.mysql.com/462>])
- Fixed `MERGE` table behavior in `ORDER BY ... DESC` queries. (Bug #515 [<http://bugs.mysql.com/515>])
- Fixed server crash on `PURGE MASTER LOGS` or `SHOW MASTER LOGS` when the binary log is off. (Bug #733 [<http://bugs.mysql.com/733>])
- Fixed password-checking problem on Windows. (Bug #464 [<http://bugs.mysql.com/464>])
- Fixed the bug in comparison of a `DATETIME` column and an integer constant. (Bug #504 [<http://bugs.mysql.com/504>])
- Fixed remote mode of **mysqlbinlog**. (Bug #672 [<http://bugs.mysql.com/672>])
- Fixed `ERROR 1105: Unknown error` that occurred for some `SELECT` queries, where a column that was declared as `NOT NULL` was compared with an expression that took `NULL` value.
- Changed timeout in `mysql_real_connect()` to use `poll()` instead of `select()` to work around problem with many open files in the client.
- Fixed incorrect results from `MATCH ... AGAINST` used with a `LEFT JOIN` query.
- Fixed a bug that limited the maximum value for **mysqld** variables to 4294967295 when they are specified on the command line.
- Fixed a bug that sometimes caused spurious "Access denied" errors in `HANDLER ... READ` statements, when a table is referenced via an alias.
- Fixed portability problem with `safe_malloc`, which caused MySQL to give "Freeing wrong aligned pointer" errors on SCO 3.2.
- `ALTER TABLE ... ENABLE/DISABLE KEYS` could cause a core dump when done after an `INSERT DELAYED` statement on the same table.
- Fixed problem with conversion of localtime to GMT where some times resulted in different (but correct) timestamps. Now MySQL should use the smallest possible timestamp value in this case. (Bug #316 [<http://bugs.mysql.com/316>])
- Very small query cache sizes could crash **mysqld**. (Bug #549 [<http://bugs.mysql.com/549>])
- Fixed a bug (accidentally introduced by us but present only in version 4.0.13) that made `INSERT ... SELECT` into an `AUTO_INCREMENT` column not replicate well. This bug is in the master, not in the slave. (Bug #490 [<http://bugs.mysql.com/490>])
- Fixed a bug: When an `INSERT ... SELECT` statement inserted rows into a non-transactional table, but failed at some point (for example, due to a "Duplicate key" error), the query was not written to the binary log. Now it is written to the binary log, with its error code, as all other queries are. About the `slave-skip-errors` option for how to handle partially completed queries in the slave, see Section 6.8, "Replication Startup Options". (Bug #491 [<http://bugs.mysql.com/491>])
- `SET FOREIGN_KEY_CHECKS=0` was not replicated properly. The fix probably will not be backported to 3.23.
- On a slave, `LOAD DATA INFILE` which had no `IGNORE` or `REPLACE` clause on the master, was replicated with `IGNORE`. While this is not a problem if the master and slave data are identical (a `LOAD` that produces no duplicate conflicts on the master produces none on the slave anyway), which is true in normal operation, it is better for debugging not to silently add the `IGNORE`. That way, you can get an error message on the slave and discover that for some reason, the data on master and slave are different and investigate why. (Bug #571 [<http://bugs.mysql.com/571>])

- On a slave, `LOAD DATA INFILE` printed an incomplete ```Duplicate entry '%-.64s' for key %d''` message (the key name and value were not mentioned) in case of duplicate conflict (which does not happen in normal operation). (Bug #573 [<http://bugs.mysql.com/573>])
- When using a slave compiled with `--debug`, `CHANGE MASTER TO RELAY_LOG_POS` could cause a debug assertion failure. (Bug #576 [<http://bugs.mysql.com/576>])
- When doing a `LOCK TABLES WRITE` on an InnoDB table, commit could not happen, if the query was not written to the binary log (for example, if `--log-bin` was not used, or `bin-log-ignore-db` was used). (Bug #578 [<http://bugs.mysql.com/578>])
- If a 3.23 master had open temporary tables that had been replicated to a 4.0 slave, and the binary log got rotated, these temporary tables were immediately dropped by the slave (which caused problems if the master used them subsequently). This bug had been fixed in 4.0.13, but in a manner which caused an unlikely inconvenience: If the 3.23 master died brutally (power failure), without having enough time to automatically write `DROP TABLE` statements to its binary log, then the 4.0.13 slave would not notice the temporary tables have to be dropped, until the slave **mysqld** server is restarted. This minor inconvenience is fixed in 3.23.57 and 4.0.14 (meaning the master must be upgraded to 3.23.57 and the slave to 4.0.14 to remove the inconvenience). (Bug #254 [<http://bugs.mysql.com/254>])
- If `MASTER_POS_WAIT()` was waiting, and the slave was idle, and the slave SQL thread terminated, `MASTER_POS_WAIT()` would wait forever. Now when the slave SQL thread terminates, `MASTER_POS_WAIT()` immediately returns `NULL` (```slave stopped''`). (Bug #651 [<http://bugs.mysql.com/651>])
- After `RESET SLAVE; START SLAVE;`, the `Relay_Log_Space` value displayed by `SHOW SLAVE STATUS` was too big by four bytes. (Bug #763 [<http://bugs.mysql.com/763>])
- If a query was ignored on the slave (because of `--replicate-ignore-table` and other similar rules), the slave still checked if the query got the same error code (0, no error) as on the master. So if the master had an error on the query (for example, ```Duplicate entry''` in a multiple-row insert), then the slave stopped and warned that the error codes didn't match. (Bug #797 [<http://bugs.mysql.com/797>])

D.3.13. Changes in release 4.0.13 (16 May 2003)

Functionality added or changed:

- `PRIMARY KEY` now implies `NOT NULL`. (Bug #390 [<http://bugs.mysql.com/390>])
- The Windows binary packages are now compiled with `--enable-local-infile` to match the Unix build configuration.
- Removed timing of tests from **mysql-test-run**. `time` does not accept all required parameters on many platforms (for example, QNX) and timing the tests is not really required (it's not a benchmark anyway).
- `SHOW MASTER STATUS` and `SHOW SLAVE STATUS` required the `SUPER` privilege; now they accept `REPLICATION CLIENT` as well. (Bug #343 [<http://bugs.mysql.com/343>])
- Added multi-threaded MyISAM repair optimization and `myisam_repair_threads` variable to enable it. See Section 5.3.3, "Server System Variables".
- Added `innodb_max_dirty_pages_pct` variable which controls amount of dirty pages allowed in InnoDB buffer pool.
- `CURRENT_USER()` and `Access denied` error messages now report the hostname exactly as it was specified in the `GRANT` command.
- Removed benchmark results from the source and binary distributions. They are still available in

the BK source tree, though.

- InnoDB tables now support `ANALYZE TABLE`.
- MySQL now issues an error when it opens a table that was created with MySQL 4.1.
- Option `--new` now changes binary items (0xFFDF) to be treated as binary strings instead of numbers by default. This fixes some problems with character sets where it's convenient to input the string as a binary item. After this change you have to convert the binary string to `INTEGER` with a `CAST` if you want to compare two binary items with each other and know which one is bigger than the other. `SELECT CAST(0xfeff AS UNSIGNED) < CAST(0xff AS UNSIGNED)`. This is the default behavior in MySQL 4.1. (Bug #152 [<http://bugs.mysql.com/152>])
- Enabled `delayed_insert_timeout` on Linux (most modern `glibc` libraries have a fixed `pthread_cond_timedwait()`). (Bug #211 [<http://bugs.mysql.com/211>])
- Don't create more insert delayed threads than given by `max_delayed_threads`. (Bug #211 [<http://bugs.mysql.com/211>])
- Changed `UPDATE ... LIMIT` to apply the limit to rows that were matched, whether or not they actually were changed. Previously the limit was applied as a restriction on the number of rows changed.
- Tuned optimizer to favor clustered index over table scan.
- `BIT_AND()` and `BIT_OR()` now return an unsigned 64-bit value.
- Added warnings to error log of why a secure connection failed (when running with `--log-warnings`).
- Deprecated options `--skip-symlink` and `--use-symbolic-links` and replaced these with `--symbolic-links`.
- The default option for `innodb_flush_log_at_trx_commit` was changed from 0 to 1 to make InnoDB tables ACID by default. See Section 15.5, "InnoDB Startup Options".
- Added a feature to `SHOW KEYS` to display keys that are disabled by `ALTER TABLE DISABLE KEYS` command.
- When using a non-existing table type with `CREATE TABLE`, first try if the default table type exists before falling back to `MyISAM`.
- Added `MEMORY` as an alias for `HEAP`.
- Renamed function `rnd` to `my_rnd` as the name was too generic and is an exported symbol in `libmysqlclient` (thanks to Dennis Haney for the initial patch).
- Portability fix: renamed `include/dbug.h` to `include/my_dbug.h`.
- **mysqldump** no longer silently deletes the binary logs when invoked with the `--master-data` or `--first-slave` option; while this behavior was convenient for some users, others may suffer from it. Now you must explicitly ask for binary logs to be deleted by using the new `--delete-master-logs` option.
- If the slave is configured (using for example `--replicate-wild-ignore-table=mysql.%`) to exclude `mysql.user`, `mysql.host`, `mysql.db`, `mysql.tables_priv` and `mysql.columns_priv` from replication, then `GRANT` and `REVOKE` are not replicated.

Bugs fixed:

- Logged `Access denied` error message had incorrect `Using password` value. (Bug #398)

[<http://bugs.mysql.com/398>])

- Fixed bug with `NATURAL LEFT JOIN`, `NATURAL RIGHT JOIN` and `RIGHT JOIN` when using many joined tables. The problem was that the `JOIN` method was not always associated with the tables surrounding the `JOIN` method. If you have a query that uses many `RIGHT JOIN` or `NATURAL ... JOINS` you should verify that they work as you expected after upgrading MySQL to this version. (Bug #291 [<http://bugs.mysql.com/291>])
- Fixed **mysql** parser not to erroneously interpret `'` or `"` characters within `/* ... */` comment as beginning a quoted string.
- **mysql** command-line client no longer looks for `*` commands inside backtick-quoted strings.
- Fixed `Unknown error` when using `UPDATE ... LIMIT`. (Bug #373 [<http://bugs.mysql.com/373>])
- Fixed problem with `ANSI mode` and `GROUP BY` with constants. (Bug #387 [<http://bugs.mysql.com/387>])
- Fixed bug with `UNION` and `OUTER JOIN`. (Bug #386 [<http://bugs.mysql.com/386>])
- Fixed bug if one used a multiple-table `UPDATE` and the query required a temporary table bigger than `tmp_table_size`. (Bug #286 [<http://bugs.mysql.com/286>])
- Run **mysql_install_db** with the `-IN-RPM` option for the Mac OS X installation to not fail on systems with improperly configured hostname configurations.
- `LOAD DATA INFILE` now reads `000000` as a zero date instead of `"2000-00-00"`.
- Fixed bug that caused `DELETE FROM table WHERE const_expression` always to delete the whole table (even if expression result was false). (Bug #355 [<http://bugs.mysql.com/355>])
- Fixed core dump bug when using `FORMAT('nan',#)`. (Bug #284 [<http://bugs.mysql.com/284>])
- Fixed name resolution bug with `HAVING ... COUNT(DISTINCT ...)`.
- Fixed incorrect result from truncation operator (`*`) in `MATCH ... AGAINST()` in some complex joins.
- Fixed a crash in `REPAIR ... USE_FRM` command, when used on read-only, non-existing table or a table with a crashed index file.
- Fixed a crashing bug in **mysql** monitor program. It occurred if program was started with `--no-defaults`, with a prompt that contained the hostname and a connection to a non-existent database was requested.
- Fixed problem when comparing a key for a multi-byte character set. (Bug #152 [<http://bugs.mysql.com/152>])
- Fixed bug in `LEFT`, `RIGHT` and `MID` when used with multi-byte character sets and some `GROUP BY` queries. (Bug #314 [<http://bugs.mysql.com/314>])
- Fix problem with `ORDER BY` being discarded for some `DISTINCT` queries. (Bug #275 [<http://bugs.mysql.com/275>])
- Fixed that `SET SQL_BIG_SELECTS=1` works as documented (This corrects a new bug introduced in 4.0)
- Fixed some serious bugs in `UPDATE ... ORDER BY`. (Bug #241 [<http://bugs.mysql.com/241>])
- Fixed unlikely problem in optimizing `WHERE` clause with constant expression like in `WHERE 1`

AND (a=1 AND b=1).

- Fixed that SET SQL_BIG_SELECTS=1 works again.
- Introduced proper backtick quoting for db.table in SHOW GRANTS.
- FULLTEXT index stopped working after ALTER TABLE that converts TEXT column to CHAR. (Bug #283 [<http://bugs.mysql.com/283>])
- Fixed a security problem with SELECT and wildcard select list, when user only had partial column SELECT privileges on the table.
- Mark a MyISAM table as "analyzed" only when all the keys are indeed analyzed.
- Only ignore world-writable my.cnf files that are regular files (and not, for example, named pipes or character devices).
- Fixed few smaller issues with SET PASSWORD.
- Fixed error message which contained deprecated text.
- Fixed a bug with two NATURAL JOINS in the query.
- SUM() didn't return NULL when there was no rows in result or when all values was NULL.
- On Unix, symbolic link handling was not enabled by default and there was no way to turn this on.
- Added missing dashes to parameter --open-files-limit in **mysqld_safe**. (Bug #264 [<http://bugs.mysql.com/264>])
- Fixed incorrect hostname for TCP/IP connections displayed in SHOW PROCESSLIST.
- Fixed a bug with NAN in FORMAT(. . .) function ...
- Fixed a bug with improperly cached database privileges.
- Fixed a bug in ALTER TABLE ENABLE / DISABLE KEYS which failed to force a refresh of table data in the cache.
- Fixed bugs in replication of LOAD DATA INFILE for custom parameters (ENCLOSED, TERMINATED and so on) and temporary tables. (Bug #183 [<http://bugs.mysql.com/183>], Bug #222 [<http://bugs.mysql.com/222>])
- Fixed a replication bug when the master is 3.23 and the slave 4.0: the slave lost the replicated temporary tables if FLUSH LOGS was issued on the master. (Bug #254 [<http://bugs.mysql.com/254>])
- Fixed a bug when doing LOAD DATA INFILE IGNORE: When reading the binary log, **mysqlbinlog** and the replication code read REPLACE instead of IGNORE. This could make the slave's table become different from the master's table. (Bug #218 [<http://bugs.mysql.com/218>])
- Fixed a deadlock when relay_log_space_limit was set to a too small value. (Bug #79 [<http://bugs.mysql.com/79>])
- Fixed a bug in HAVING clause when an alias is used from the **select list**.
- Fixed overflow bug in MyISAM when a row is inserted into a table with a large number of columns and at least one BLOB/TEXT column. Bug was caused by incorrect calculation of the needed buffer to pack data.
- Fixed a bug when SELECT @**nonexistent_variable** caused the error in client - server protocol due to net_printf() being sent to the client twice.

- Fixed a bug in setting `SQL_BIG_SELECTS` option.
- Fixed a bug in `SHOW PROCESSLIST` which only displayed a localhost in the "Host" column. This was caused by a glitch that used only current thread information instead of information from the linked list of threads.
- Removed unnecessary Mac OS X helper files from server RPM. (Bug #144 [<http://bugs.mysql.com/144>])
- Allow optimization of multiple-table update for InnoDB tables as well.
- Fixed a bug in multiple-table updates that caused some rows to be updated several times.
- Fixed a bug in `mysqldump` when it was called with `--master-data`: the `CHANGE MASTER TO` commands appended to the SQL dump had incorrect coordinates. (Bug #159 [<http://bugs.mysql.com/159>])
- Fixed a bug when an updating query using `USER()` was replicated on the slave; this caused seg-fault on the slave. (Bug #178 [<http://bugs.mysql.com/178>]). `USER()` is still badly replicated on the slave (it is replicated to " ").

D.3.14. Changes in release 4.0.12 (15 Mar 2003: Production)

Functionality added or changed:

- `mysqld` no longer reads options from world-writable config files. (CAN-2003-0150 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2003-0150>])
- Integer values between 9223372036854775807 and 999999999999999999 are now regarded as unsigned longlongs, not as floats. This makes these values work similar to values between 1000000000000000000 and 18446744073709551615.
- `SHOW PROCESSLIST` now includes the client TCP port after the hostname to make it easier to know from which client the request originated.
- The `--new` option can be used to make a 4.0 server return `TIMESTAMP` as a string in 'YYYY-MM-DD HH:MM:SS' format, the way that 4.1 servers do. This is also a new system variable that can be set for the same effect. See Section 11.3.1.1, "TIMESTAMP Properties Prior to MySQL 4.1".

Bugs fixed:

- Fixed `mysqld` crash on extremely small values of `sort_buffer` variable.
- `INSERT INTO u SELECT ... FROM t` was written too late to the binary log if `t` was very frequently updated during the execution of this query. This could cause a problem with `mysql-binlog` or replication. The master must be upgraded, not the slave. (Bug #136 [<http://bugs.mysql.com/136>])
- Fixed checking of random part of `WHERE` clause. (Bug #142 [<http://bugs.mysql.com/142>])
- Fixed a bug with multiple-table updates with InnoDB tables. This bug occurred as, in many cases, InnoDB tables cannot be updated "on the fly," but offsets to the records have to be stored in a temporary table.
- Added missing file `mysql_secure_installation` to the server RPM subpackage. (Bug #141 [<http://bugs.mysql.com/141>])

- Fixed MySQL (and **myisamchk**) crash on artificially corrupted .MYI files.
- Don't allow BACKUP TABLE to overwrite existing files.
- Fixed a bug with multiple-table UPDATE statements when user had all privileges on the database where tables are located and there were any entries in tables_priv table, that is, grant_option was true.
- Fixed a bug that allowed a user with table or column grants on some table, TRUNCATE any table in the same database.
- Fixed deadlock when doing LOCK TABLE followed by DROP TABLE in the same thread. In this case one could still kill the thread with KILL.
- LOAD DATA LOCAL INFILE was not properly written to the binary log (hence not properly replicated). (Bug #82 [<http://bugs.mysql.com/82>])
- RAND() entries were not read correctly by **mysqlbinlog** from the binary log which caused problems when restoring a table that was inserted with RAND(). INSERT INTO t1 VALUES (RAND()). In replication this worked okay.
- SET SQL_LOG_BIN=0 was ignored for INSERT DELAYED queries. (Bug #104 [<http://bugs.mysql.com/104>])
- SHOW SLAVE STATUS reported too old positions (columns Relay_Master_Log_File and Exec_Master_Log_Pos) for the last executed statement from the master, if this statement was the COMMIT of a transaction. The master must be upgraded for that, not the slave. (Bug #52 [<http://bugs.mysql.com/52>])
- LOAD DATA INFILE was not replicated by the slave if replicate_*_table was set on the slave. (Bug #86 [<http://bugs.mysql.com/86>])
- After RESET SLAVE, the coordinates displayed by SHOW SLAVE STATUS looked un-reset (although they were, but only internally). (Bug #70 [<http://bugs.mysql.com/70>])
- Fixed query cache invalidation on LOAD DATA.
- Fixed memory leak on ANALYZE procedure with error.
- Fixed a bug in handling CHAR(0) columns that could cause incorrect results from the query.
- Fixed rare bug with incorrect initialization of AUTO_INCREMENT column, as a secondary column in a multi-column key (see Section 3.6.9, "Using AUTO_INCREMENT"), when data was inserted with INSERT . . . SELECT or LOAD DATA into an empty table.
- On Windows, STOP SLAVE didn't stop the slave until the slave got one new command from the master (this bug has been fixed for MySQL 4.0.11 by releasing updated 4.0.11a Windows packages, which include this individual fix on top of the 4.0.11 sources). (Bug #69 [<http://bugs.mysql.com/69>])
- Fixed a crash when no database was selected and LOAD DATA command was issued with full table name specified, including database prefix.
- Fixed a crash when shutting down replication on some platforms (for example, Mac OS X).
- Fixed a portability bug with pthread_attr_getstacksize on HP-UX 10.20 (Patch was also included in 4.0.11a sources).
- Fixed the bigint test to not fail on some platforms (for example, HP-UX and Tru64) due to different return values of the atof() function.
- Fixed the rpl_rotate_logs test to not fail on certain platforms (such as Mac OS X) due to a too-long file name (changed slave-master-info.opt to .slave-mi).

D.3.15. Changes in release 4.0.11 (20 Feb 2003)

Functionality added or changed:

- NULL is now sorted **LAST** if you use `ORDER BY . . . DESC` (as it was before MySQL 4.0.2). This change was required to comply with the SQL standard. (The original change was made because we thought that standard SQL required NULL to be always sorted at the same position, but this was incorrect).
- Added `START TRANSACTION` (standard SQL syntax) as alias for `BEGIN`. This is recommended to use instead of `BEGIN` to start a transaction.
- Added `OLD_PASSWORD()` as a synonym for `PASSWORD()`.
- Allow keyword `ALL` in group functions.
- Added support for some new `INNER JOIN` and `JOIN` syntaxes. For example, `SELECT * FROM t1 INNER JOIN t2` didn't work before.
- Novell NetWare 6.0 porting effort completed, Novell patches merged into the main source tree.

Bugs fixed:

- Fixed problem with multiple-table delete and InnoDB tables.
- Fixed a problem with `BLOB NOT NULL` columns used with `IS NULL`.
- Re-added missing pre- and post(un)install scripts to the Linux RPM packages (they were missing after the renaming of the server subpackage).
- Fixed that table locks are not released with multiple-table updates and deletes with InnoDB storage engine.
- Fixed bug in updating BLOB columns with long strings.
- Fixed integer-wraparound when giving big integer (≥ 10 digits) to function that requires an unsigned argument, like `CREATE TABLE (. . .) AUTO_INCREMENT=#`.
- `MIN(key_column)` could in some cases return NULL on a column with NULL and other values.
- `MIN(key_column)` and `MAX(key_column)` could in some cases return incorrect values when used in `OUTER JOIN`.
- `MIN(key_column)` and `MAX(key_column)` could return incorrect values if one of the tables was empty.
- Fixed rare crash in compressed MyISAM tables with blobs.
- Fixed bug in using aggregate functions as argument for `INTERVAL`, `CASE`, `FIELD`, `CONCAT_WS`, `ELT` and `MAKE_SET` functions.
- When running with `--lower-case-table-names` (default on Windows) and you had tables or databases with mixed case on disk, then executing `SHOW TABLE STATUS` followed with `DROP DATABASE` or `DROP TABLE` could fail with `Errcode 13`.

D.3.16. Changes in release 4.0.10 (29 Jan 2003)

Functionality added or changed:

- Added option `--log-error[=file_name]` to **mysqld_safe** and **mysqld**. This option forces all error messages to be put in a log file if the option `--console` is not given. On Windows `--log-error` is enabled as default, with a default name of `host_name.err` if the name is not specified.
- Changed some things from `Warning:` to `Note:` in the log files.
- The **mysqld** server should now compile on NetWare.
- Added optimization that if one does `GROUP BY ... ORDER BY NULL` then result is not sorted.
- New `--ft-stopword-file` command-line option for **mysqld** to replace/disable the built-in stopword list that is used in full-text searches. See Section 5.3.3, “Server System Variables”.
- Changed default stack size from 64KB to 192KB; This fixes a core dump problem on Red Hat 8.0 and other systems with a `glibc` that requires a stack size larger than 128K for `gethostbyaddr()` to resolve a hostname. You can fix this for earlier MySQL versions by starting **mysqld** with `--thread-stack=192K`.
- Added `mysql_waitpid` to the binary distribution and the `MySQL-client` RPM subpackage (required for **mysql-test-run**).
- Renamed the main MySQL RPM package to `MySQL-server`. When updating from an older version, `MySQL-server.rpm` simply replaces `MySQL.rpm`.
- If a slave is configured with `replicate_wild_do_table=db.%` or `replicate_wild_ignore_table=db.%`, these rules are applied to `CREATE/DROP DATABASE`, too.
- Added timeout value for `MASTER_POS_WAIT()`.

Bugs fixed:

- Fixed initialization of the random seed for newly created threads to give a better `rand()` distribution from the first call.
- Fixed a bug that caused **mysqld** to hang when a table was opened with the `HANDLER` command and then dropped without being closed.
- Fixed bug in logging to binary log (which affects replication) a query that inserts a `NULL` in an `AUTO_INCREMENT` column and also uses `LAST_INSERT_ID()`.
- Fixed an unlikely bug that could cause a memory overrun when using `ORDER BY constant_expression`.
- Fixed a table corruption in **myisamchk** parallel repair mode.
- Fixed bug in query cache invalidation on simple table renaming.
- Fixed bug in **mysqladmin --relative**.
- On some 64-bit systems, `show status` reported a strange number for `Open_files` and `Open_streams`.
- Fixed incorrect number of columns in `EXPLAIN` on empty table.
- Fixed bug in `LEFT JOIN` that caused zero rows to be returned in the case the `WHERE` condition was evaluated as `FALSE` after reading `const` tables. (Unlikely condition).
- `FLUSH PRIVILEGES` didn't correctly flush table/column privileges when `mysql.tables_priv` is empty.

- Fixed bug in replication when using `LOAD DATA INFILE` one a file that updated an `AUTO_INCREMENT` column with `NULL` or `0`. This bug only affected MySQL 4.0 masters (not slaves or MySQL 3.23 masters). **Note:** If you have a slave that has replicated a file with generated `AUTO_INCREMENT` columns then the slave data is corrupted and you should reinitialize the affected tables from the master.
- Fixed possible memory overrun when sending a `BLOB` value larger than 16M to the client.
- Fixed incorrect error message when setting a `NOT NULL` column to an expression that returned `NULL`.
- Fixed core dump bug in `str LIKE "%other_str%"` where `str` or `other_str` contained characters ≥ 128 .
- Fixed bug: When executing on master `LOAD DATA` and InnoDB failed with `table full` error the binary log was corrupted.

D.3.17. Changes in release 4.0.9 (09 Jan 2003)

Functionality added or changed:

- `OPTIMIZE TABLE` for MyISAM tables treats all `NULL` values as different when calculating cardinality. This helps in optimizing joins between tables where one of the tables has a lot of `NULL` values in a indexed column:

```
SELECT * from t1, t2 where t1.a=t2.key_with_a_lot_of_null;
```

- Added join operator `FORCE INDEX (key_list)`. This acts likes `USE INDEX (key_list)` but with the addition that a table scan is assumed to be `VERY` expensive. One bad thing with this is that it makes `FORCE` a reserved word.
- Reset internal row buffer in MyISAM after each query. This reduces memory in case you have a lot of big blobs in a table.

Bugs fixed:

- A security patch in 4.0.8 causes the `mysqld` server to die if the remote hostname can't be resolved. This is now fixed.
- Fixed crash when replication big `LOAD DATA INFILE` statement that caused log rotation.

D.3.18. Changes in release 4.0.8 (07 Jan 2003)

Functionality added or changed:

- Default `max_packet_length` for `libmysqld.c` is now `1024*1024*1024`.
- You can now specify `max_allowed_packet` in a file read by `mysql_options(MYSQL_READ_DEFAULT_FILE)`. for clients.
- When sending a too big packet to the server with the not compressed protocol, the client now gets an error message instead of a lost connection.
- We now send big queries/result rows in bigger hunks, which should give a small speed improvement.

- Fixed some bugs with the compressed protocol for rows > 16MB.
- InnoDB tables now also support ON UPDATE CASCADE in FOREIGN KEY constraints. See the InnoDB section in the manual for the InnoDB changelog.

Bugs fixed:

- Fixed bug in ALTER TABLE with BDB tables.
- Fixed core dump bug in QUOTE () function.
- Fixed a bug in handling communication packets bigger than 16MB. Unfortunately this required a protocol change; If you upgrade the server to 4.0.8 and above and have clients that use packets >= 255*255*255 bytes (=16581375) you must also upgrade your clients to at least 4.0.8. If you don't upgrade, the clients hang when sending a big packet.
- Fixed bug when sending blobs longer than 16MB to client.
- Fixed bug in GROUP BY when used on BLOB column with NULL values.
- Fixed a bug in handling NULL values in CASE ... WHEN ...

D.3.19. Changes in release 4.0.7 (20 Dec 2002)

Functionality added or changed:

- **mysqlbug** now also reports the compiler version used for building the binaries (if the compiler supports the option `--version`).

Bugs fixed:

- Fixed compilation problems on OpenUnix and HP-UX 10.20.
- Fixed some optimization problems when compiling MySQL with `-DBIG_TABLES` on a 32-bit system.
- `mysql_drop_db()` didn't check permissions properly so anyone could drop another users database. `DROP DATABASE` is checked properly.

D.3.20. Changes in release 4.0.6 (14 Dec 2002: Gamma)

Functionality added or changed:

- Added syntax support for `CHARACTER SET xxx` and `CHARSET=xxx` table options (to be able to read table dumps from 4.1).
- Fixed replication bug that caused the slave to lose its position in some cases when the replication log was rotated.
- Fixed that a slave restarts from the start of a transaction if it's killed in the middle of one.
- Moved the manual pages from `man` to `man/man1` in the binary distributions.
- The default type returned by `IFNULL(A, B)` is now set to be the more 'general' of the types of A and B. (The order is `STRING`, `REAL` or `INTEGER`).

- Moved the **mysql.server** startup script in the RPM packages from `/etc/rc.d/init.d/mysql` to `/etc/init.d/mysql` (which almost all current Linux distributions support for LSB compliance).
- Added `Qcache_lowmem_prunes` status variable (number of queries that were deleted from the cache because of low memory).
- Fixed **mysqlcheck** so it can deal with table names containing dashes.
- Bulk insert optimization (see Section 5.3.3, “Server System Variables”) is no longer used when inserting small (less than 100) number of rows.
- Optimization added for queries like `SELECT ... FROM merge_table WHERE indexed_column=constant_expr`.
- Added functions `LOCALTIME` and `LOCALTIMESTAMP` as synonyms for `NOW()`.
- `CEIL` is now an alias for `CEILING`.
- The `CURRENT_USER()` function can be used to get a `user@host` value as it was matched in the `GRANT` system. See Section 12.8.3, “Information Functions”.
- Fixed `CHECK` constraints to be compatible with standard SQL. This made `CHECK` a reserved word. (Checking of `CHECK` constraints is still not implemented).
- Added `CAST(... as CHAR)`.
- Added PostgreSQL compatible `LIMIT` syntax: `SELECT ... LIMIT row_count OFFSET offset`
- `mysql_change_user()` now resets the connection to the state of a fresh connect (i.e., `ROLLBACK` any active transaction, close all temporary tables, reset all user variables etc..)
- `CHANGE MASTER` and `RESET SLAVE` now require that slave threads both be stopped; these commands return an error if at least one of these two threads is running.

Bugs fixed:

- Fixed number of found rows returned in `multi table updates`
- Make `--lower-case-table-names` default on Mac OS X as the default filesystem (HFS+) is case insensitive. See Section 9.2.2, “Identifier Case Sensitivity”.
- Transactions in `AUTOCOMMIT=0` mode didn't rotate binary log.
- A fix for the bug in a `SELECT` with joined tables with `ORDER BY` and `LIMIT` clause when `filesort` had to be used. In that case `LIMIT` was applied to `filesort` of one of the tables, although it could not be. This fix also solved problems with `LEFT JOIN`.
- `mysql_server_init()` now makes a copy of all arguments. This fixes a problem when using the embedded server in C# program.
- Fixed buffer overrun in `libmysqlclient` library that allowed a malicious MySQL server to crash the client application. (CAN-2002-1376 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2002-1376>])
- Fixed security-related bug in `mysql_change_user()` handling. All users are strongly recommended to upgrade to version 4.0.6. (CVE-2002-1374 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1374>], CVE-2002-1375 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1375>])
- Fixed bug that prevented `--chroot` command-line option of **mysqld** from working.

- Fixed bug in phrase operator " . . . " in boolean full-text search.
- Fixed bug that caused `OPTIMIZE TABLE` to corrupt the table under some rare circumstances.
- Part rewrite of multiple-table-update to optimize it, make it safer and more bug-free.
- `LOCK TABLES` now works together with multiple-table-update and multiple-table-delete.
- `--replicate-do=xxx` didn't work for `UPDATE` commands. (Bug introduced in 4.0.0)
- Fixed shutdown problem on Mac OS X.
- Major InnoDB bugs in `REPLACE`, `AUTO_INCREMENT`, `INSERT INTO . . . SELECT . . .` were fixed. See the InnoDB changelog in the InnoDB section of the manual.
- `RESET SLAVE` caused a crash if the slave threads were running.

D.3.21. Changes in release 4.0.5 (13 Nov 2002)

Functionality added or changed:

- Port number was added to hostname (if it is known) in `SHOW PROCESSLIST` command
- Changed handling of last argument in `WEEK()` so that you can get week number according to the ISO 8601 specification. (Old code should still work).
- Fixed that `INSERT DELAYED` threads don't hang on `Waiting for INSERT` when one sends a `SIGHUP` to **mysqld**.
- Change that `AND` works according to standard SQL when it comes to `NULL` handling. In practice, this affects only queries where you do something like `WHERE . . . NOT (NULL AND 0)`.
- **mysqld** now resolves `basedir` to its full path (with `realpath()`). This enables one to use relative symlinks to the MySQL installation directory. This however causes `show variables` to report different directories on systems where there is a symbolic link in the path.
- Fixed that MySQL does not use index scan on index disabled with `IGNORE INDEX` or `USE INDEX`. to be ignored.
- Added `--use_frm` option to **mysqlcheck**. When used with `REPAIR TABLE`, it gets the table structure from the `.frm` file, so the table can be repaired even if the `.MYI` header is corrupted.
- Fixed bug in `MAX()` optimization when used with `JOIN` and `ON` expressions.
- Added support for reading of MySQL 4.1 table definition files.
- `BETWEEN` behavior changed (see Section 12.1.3, "Comparison Functions and Operators"). Now `datetime_col BETWEEN timestamp AND timestamp` should work as expected.
- One can create `TEMPORARY MERGE` tables now.
- `DELETE FROM myisam_table` now shrinks not only the `.MYD` file but also the `.MYI` file.
- When one uses the `--open-files-limit=#` option to **mysqld_safe** it's now passed on to **mysqld**.
- Changed output from `EXPLAIN` from `'where used'` to `'Using where'` to make it more in line with other output.
- Removed variable `safe_show_database` as it was no longer used.

- Updated source tree to be built using **automake 1.5** and **libtool 1.4**.
- Fixed an inadvertently changed option (`--ignore-space`) back to the original `-ignore-spaces` in `mysqlclient`. (Both syntaxes work).
- Don't require UPDATE privilege when using REPLACE.
- Added support for `DROP TEMPORARY TABLE . . .`, to be used to make replication safer.
- When transactions are enabled, all commands that update temporary tables inside a BEGIN/COMMIT are now stored in the binary log on COMMIT and not stored if one does ROLLBACK. This fixes some problems with non-transactional temporary tables used inside transactions.
- Allow braces in joins in all positions. Formerly, things like `SELECT * FROM (t2 LEFT JOIN t3 USING (a)), t1` worked, but not `SELECT * FROM t1, (t2 LEFT JOIN t3 USING (a))`. Note that braces are simply removed, they do not change the way the join is executed.
- InnoDB now supports also isolation levels READ UNCOMMITTED and READ COMMITTED. For a detailed InnoDB changelog, see Section D.9, "InnoDB Change History" in this manual.

Bugs fixed:

- Fixed bug in `MAX()` optimization when used with JOIN and ON expressions.
- Fixed that `INSERT DELAY` threads don't hang on `Waiting for INSERT` when one sends a `SIGHUP` to **mysqld**.
- Fixed that MySQL does not use an index scan on an index that has been disabled with `IGNORE INDEX` or `USE INDEX`.
- Corrected test for `root` user in **mysqld_safe**.
- Fixed error message issued when storage engine cannot do `CHECK TABLE` or `REPAIR TABLE`.
- Fixed rare core dump problem in complicated `GROUP BY` queries that didn't return any result.
- Fixed **mysqlshow** to work properly with wildcarded database names and with database names that contain underscores.
- Portability fixes to get MySQL to compile cleanly with Sun Forte 5.0.
- Fixed MyISAM crash when using dynamic-row tables with huge numbers of packed columns.
- Fixed query cache behavior with BDB transactions.
- Fixed possible floating point exception in `MATCH` relevance calculations.
- Fixed bug in full-text search `IN BOOLEAN MODE` that made `MATCH` to return incorrect relevance value in some complex joins.
- Fixed a bug that limited MyISAM key length to a value slightly less than 500. It is exactly 500 now.
- Fixed that `GROUP BY` on columns that may have a NULL value doesn't always use disk based temporary tables.
- The filename argument for the `--des-key-file` argument to **mysqld** is interpreted relative to the data directory if given as a relative pathname.
- Removed a condition that temp table with index on column that can be NULL has to be

. This was okay for 3.23, but not needed in 4.*. This resulted in slowdown in many queries since 4.0.2.

- Small code improvement in multiple-table updates.
- Fixed a newly introduced bug that caused `ORDER BY ... LIMIT row_count` to not return all rows.
- Fixed a bug in multiple-table deletes when outer join is used on an empty table, which gets first to be deleted.
- Fixed a bug in multiple-table updates when a single table is updated.
- Fixed bug that caused `REPAIR TABLE` and **myisamchk** to corrupt FULLTEXT indexes.
- Fixed bug with caching the `mysql` grant table database. Now queries in this database are not cached in the query cache.
- Small fix in **mysqld_safe** for some shells.
- Give error if a MyISAM MERGE table has more than 2^{32} rows and MySQL was not compiled with `-DBIG_TABLES`.
- Fixed some `ORDER BY ... DESC` problems with InnoDB tables.

D.3.22. Changes in release 4.0.4 (29 Sep 2002)

- Fixed bug where `GRANT/REVOKE` failed if hostname was given in non-matching case.
- Don't give warning in `LOAD DATA INFILE` when setting a `timestamp` to a string value of `'0'`.
- Fixed bug in **myisamchk -R** mode.
- Fixed bug that caused **mysqld** to crash on `REVOKE`.
- Fixed bug in `ORDER BY` when there is a constant in the `SELECT` statement.
- One didn't get an error message if **mysqld** couldn't open the privilege tables.
- `SET PASSWORD FOR ...` closed the connection in case of errors (bug from 4.0.3).
- Increased maximum possible `max_allowed_packet` in **mysqld** to 1GB.
- Fixed bug when doing a multiple-row `INSERT` on a table with an `AUTO_INCREMENT` key which was not in the first part of the key.
- Changed `LOAD DATA INFILE` to not re-create index if the table had rows from before.
- Fixed overrun bug when calling `AES_DECRYPT()` with incorrect arguments.
- `--skip-ssl` can now be used to disable SSL in the MySQL clients, even if one is using other SSL options in an option file or previously on the command line.
- Fixed bug in `MATCH ... AGAINST(... IN BOOLEAN MODE)` used with `ORDER BY`.
- Added `LOCK TABLES` and `CREATE TEMPORARY TABLES` privilege on the database level. You must run the **mysql_fix_privilege_tables** script on old installations to activate these.
- In `SHOW TABLE ... STATUS`, compressed tables sometimes showed up as `dynamic`.
- `SELECT @@[global|session].var_name` didn't report `global | session` in the

result column name.

- Fixed problem in replication that `FLUSH LOGS` in a circular replication setup created an infinite number of binary log files. Now a `rotate-binary-log` command in the binary log does not cause slaves to rotate logs.
- Removed `STOP EVENT` from binary log when doing `FLUSH LOGS`.
- Disable the use of `SHOW NEW MASTER FOR SLAVE` as this needs to be completely reworked in a future release.
- Fixed a bug with constant expression (for example, column of a one-row table, or column from a table, referenced by a `UNIQUE` key) appeared in `ORDER BY` part of `SELECT DISTINCT`.
- `--log-binary=a.b.c` now properly strips off `.b.c`.
- `FLUSH LOGS` removed numerical extension for all future update logs.
- `GRANT ... REQUIRE` didn't store the SSL information in the `mysql.user` table if SSL was not enabled in the server.
- `GRANT ... REQUIRE NONE` can now be used to remove SSL information.
- `AND` is now optional between `REQUIRE` options.
- `REQUIRE` option was not properly saved, which could cause strange output in `SHOW GRANTS`.
- Fixed that **mysqld --help** reports correct values for `--datadir` and `--bind-address`.
- Fixed that one can drop UDFs that didn't exist when **mysqld** was started.
- Fixed core dump problem with `SHOW VARIABLES` on some 64-bit systems (like Solaris SPARC).
- Fixed a bug in `my_getopt()`; `--set-variable` syntax didn't work for those options that didn't have a valid variable in the `my_option` struct. This affected at least the `default-table-type` option.
- Fixed a bug from 4.0.2 that caused `REPAIR TABLE` and **myisamchk --recover** to fail on tables with duplicates in a unique key.
- Fixed a bug from 4.0.3 in calculating the default data type for some functions. This affected queries of type `CREATE TABLE tbl_name SELECT expression(),...`
- Fixed bug in queries of type `SELECT * FROM table-list GROUP BY ...` and `SELECT DISTINCT * FROM`
- Fixed bug with the `--slow-log` when logging an administrator command (like `FLUSH TABLES`).
- Fixed a bug that `OPTIMIZE TABLE` of locked and modified table, reported table corruption.
- Fixed a bug in `my_getopt()` in handling of special prefixes (`--skip-`, `--enable-`). `--skip-external-locking` didn't work and the bug may have affected other similar options.
- Fixed bug in checking for output file name of the `tee` option.
- Added some more optimization to use index for `SELECT ... FROM many_tables .. ORDER BY key limit #`
- Fixed problem in `SHOW OPEN TABLES` when a user didn't have access permissions to one of the opened tables.

D.3.23. Changes in release 4.0.3 (26 Aug 2002: Beta)

- Fixed problem with types of user variables. (Bug #551 [<http://bugs.mysql.com/551>])
- Fixed problem with `configure ... --localstatedir=...`
- Cleaned up **mysql.server** script.
- Fixed a bug in **mysqladmin shutdown** when pid file was modified while **mysqladmin** was still waiting for the previous one to disappear. This could happen during a very quick restart and caused **mysqladmin** to hang until `shutdown_timeout` seconds had passed.
- Don't increment warnings when setting `AUTO_INCREMENT` columns to `NULL` in `LOAD DATA INFILE`.
- Fixed all boolean type variables/options to work with the old syntax, for example, all of these work: `--lower-case-table-names`, `--lower-case-table-names=1`, `-O lower-case-table-names=1`, `--set-variable=lower-case-table-names=1`
- Fixed shutdown problem (SIGTERM signal handling) on Solaris. (Bug from 4.0.2).
- `SHOW MASTER STATUS` now returns an empty set if binary log is not enabled.
- `SHOW SLAVE STATUS` now returns an empty set if slave is not initialized.
- Don't update MyISAM index file on update if not strictly necessary.
- Fixed bug in `SELECT DISTINCT ... FROM many_tables ORDER BY not-used-column`.
- Fixed a bug with `BIGINT` values and quoted strings.
- Added `QUOTE()` function that performs SQL quoting to produce values that can be used as data values in queries.
- Changed variable `DELAY_KEY_WRITE` to an enumeration to allow it to be set for all tables without taking down the server.
- Changed behavior of `IF(condition, column, NULL)` so that it returns the value of the column type.
- Made **safe_mysql** a symlink to **mysql_safe** in binary distribution.
- Fixed security bug when having an empty database name in the `user.db` table.
- Fixed some problems with `CREATE TABLE ... SELECT function()`.
- **mysql** now has the option `--temp-pool` enabled by default as this gives better performance with some operating systems.
- Fixed problem with too many allocated alarms on slave when connecting to master many times (normally not a very critical error).
- Fixed hang in `CHANGE MASTER TO` if the slave thread died very quickly.
- Big cleanup in replication code (less logging, better error messages, etc..)
- If the `--code-file` option is specified, the server calls `setrlimit()` to set the maximum allowed core file size to unlimited, so core files can be generated.
- Fixed bug in query cache after temporary table creation.
- Added `--count=N (-c)` option to **mysqladmin**, to make the program do only *N* iterations. To

be used with `--sleep (-i)`. Useful in scripts.

- Fixed bug in multiple-table UPDATE: when updating a table, `do_select()` became confused about reading records from a cache.
- Fixed bug in multiple-table UPDATE when several columns were referenced from a single table
- Fixed bug in truncating non-existing table.
- Fixed bug in REVOKE that caused user resources to be randomly set.
- Fixed bug in GRANT for the new CREATE TEMPORARY TABLE privilege.
- Fixed bug in multiple-table DELETE when tables are re-ordered in the table initialization method and `ref_lengths` are of different sizes.
- Fixed two bugs in SELECT DISTINCT with large tables.
- Fixed bug in query cache initialization with very small query cache size.
- Allow DEFAULT with INSERT statement.
- The startup parameters `myisam_max_sort_file_size` and `myisam_max_extra_sort_file_size` are now given in bytes, not megabytes.
- External system locking of MyISAM/ISAM files is now turned off by default. One can turn this on with `--external-locking`. (For most users this is never needed).
- Fixed core dump bug with `INSERT ... SET db_name.tbl_name.col_name=''`.
- Fixed client hangup bug when using some SQL commands with incorrect syntax.
- Fixed a timing bug in DROP DATABASE
- New SET [GLOBAL | SESSION] syntax to change thread-specific and global system variables at runtime.
- Added variable `slave_compressed_protocol`.
- Renamed variable `query_cache_startup_type` to `query_cache_type`, `myisam_bulk_insert_tree_size` to `bulk_insert_buffer_size`, `record_buffer` to `read_buffer_size` and `record_rnd_buffer` to `read_rnd_buffer_size`.
- Renamed some SQL variables, but old names still work until 5.0. See Section 2.10.3, “Upgrading from Version 3.23 to 4.0”.
- Renamed `--skip-locking` to `--skip-external-locking`.
- Removed unused variable `query_buffer_size`.
- Fixed a bug that made the pager option in the **mysql** client non-functional.
- Added full AUTO_INCREMENT support to MERGE tables.
- Extended LOG() function to accept an optional arbitrary base parameter. See Section 12.4.2, “Mathematical Functions”.
- Added LOG2() function (useful for finding out how many bits a number would require for storage).
- Added LN() natural logarithm function for compatibility with other databases. It is synonymous with LOG(X).

D.3.24. Changes in release 4.0.2 (01 Jul 2002)

- Cleaned up NULL handling for default values in `DESCRIBE tbl_name`.
- Fixed `TRUNCATE()` to round up negative values to the nearest integer.
- Fixed buffer overflow problem if someone specified a too-long `datadir` parameter to `mysqld`. (CVE-2002-0969 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0969>])
- Changed `--chroot=path` option to execute `chroot()` immediately after all options have been parsed.
- Don't allow database names that contain `'\'`.
- `lower_case_table_names` now also applies to database names.
- Added XOR operator (logical and bitwise XOR) with `^` as a synonym for bitwise XOR.
- Added function `IS_FREE_LOCK("lock_name")`. Based on code contributed by Hartmut Holzgraefe <hartmut@six.de>.
- Removed `mysql_ssl_clear()` from C API, as it was not needed.
- `DECIMAL` and `NUMERIC` types can now read exponential numbers.
- Added `SHA1()` function to calculate 160 bit hash value as described in RFC 3174 (Secure Hash Algorithm). This function can be considered a cryptographically more secure equivalent of `MD5()`. See Section 12.8.2, "Encryption Functions".
- Added `AES_ENCRYPT()` and `AES_DECRYPT()` functions to perform encryption according to AES standard (Rijndael). See Section 12.8.2, "Encryption Functions".
- Added `--single-transaction` option to `mysqldump`, allowing a consistent dump of InnoDB tables. See Section 8.8, "The `mysqldump` Database Backup Program".
- Fixed bug in `innodb_log_group_home_dir` in `SHOW VARIABLES`.
- Fixed a bug in optimizer with merge tables when non-unique values are used in summing up (causing crashes).
- Fixed a bug in optimizer when a range specified makes index grouping impossible (causing crashes).
- Fixed a rare bug when `FULLTEXT` index is present and no tables are used.
- Added privileges `CREATE TEMPORARY TABLES`, `EXECUTE`, `LOCK TABLES`, `REPLICATION CLIENT`, `REPLICATION SLAVE`, `SHOW DATABASES` and `SUPER`. To use these, you must have run the `mysql_fix_privilege_tables` script after upgrading.
- Fixed query cache align data bug.
- Fixed mutex bug in replication when reading from master fails.
- Added missing mutex in `TRUNCATE TABLE`. This fixes some core dump/hangup problems when using `TRUNCATE TABLE`.
- Fixed bug in multiple-table `DELETE` when optimizer uses only indexes.
- Fixed that `ALTER TABLE tbl_name RENAME new_tbl_name` is as fast as `RENAME TABLE`.
- Fixed bug in `GROUP BY` with two or more columns, where at least one column can contain NULL values.

- Use Turbo Boyer-Moore algorithm to speed up `LIKE "%keyword%"` searches.
- Fixed bug in `DROP DATABASE` with symlink.
- Fixed crash in `REPAIR ... USE_FRM`.
- Fixed bug in `EXPLAIN` with `LIMIT offset != 0`.
- Fixed bug in phrase operator `"..."` in boolean full-text search.
- Fixed bug that caused duplicated rows when using truncation operator `*` in boolean full-text search.
- Fixed bug in truncation operator of boolean full-text search (incorrect results when there are only `+word*s` in the query).
- Fixed bug in boolean full-text search that caused a crash when an identical `MATCH` expression that did not use an index appeared twice.
- Query cache is now automatically disabled in **mysqldump**.
- Fixed problem on Windows 98 that made sending of results very slow.
- Boolean full-text search weighting scheme changed to something more reasonable.
- Fixed bug in boolean full-text search that caused MySQL to ignore queries of `ft_min_word_len` characters.
- Boolean full-text search now supports ``phrase searches``.
- New configure option `--without-query-cache`.
- Memory allocation strategy for ``root memory`` changed. Block size now grows with number of allocated blocks.
- `INET_NTOA()` now returns `NULL` if you give it an argument that is too large (greater than the value corresponding to `255.255.255.255`).
- Fix `SQL_CALC_FOUND_ROWS` to work with `UNION`. It works only if the first `SELECT` has this option and if there is global `LIMIT` for the entire statement. For the moment, this requires using parentheses for individual `SELECT` queries within the statement.
- Fixed bug in `SQL_CALC_FOUND_ROWS` and `LIMIT`.
- Don't give an error for `CREATE TABLE ... (... VARCHAR(0))`.
- Fixed `SIGINT` and `SIGQUIT` problems in `mysql.cc` on Linux with some `glibc` versions.
- Fixed bug in `convert.cc`, which is caused by having an incorrect `net_store_length()` linked in the `CONVERT::store()` method.
- `DOUBLE` and `FLOAT` columns now honor the `UNSIGNED` flag on storage.
- InnoDB now retains foreign key constraints through `ALTER TABLE` and `CREATE/DROP INDEX`.
- InnoDB now allows foreign key constraints to be added through the `ALTER TABLE` syntax.
- InnoDB tables can now be set to automatically grow in size (autoextend).
- Added `--ignore-lines=n` option to **mysqlimport**. This has the same effect as the `IGNORE n LINES` clause for `LOAD DATA`.
- Fixed bug in `UNION` with last offset being transposed to total result set.

- REPAIR ... USE_FRM added.
- Fixed that DEFAULT_SELECT_LIMIT is always imposed on UNION result set.
- Fixed that some SELECT options can appear only in the first SELECT.
- Fixed bug with LIMIT with UNION, where last select is in the braces.
- Fixed that full-text works fine with UNION operations.
- Fixed bug with indexless boolean full-text search.
- Fixed bug that sometimes appeared when full-text search was used with const tables.
- Fixed incorrect error value when doing a SELECT with an empty HEAP table.
- Use ORDER BY column DESC now sorts NULL values first. (In other words, NULL values sort first in all cases, whether or not DESC is specified.) This is changed back in 4.0.10.
- Fixed bug in WHERE key_name='constant' ORDER BY key_name DESC.
- Fixed bug in SELECT DISTINCT ... ORDER BY DESC optimization.
- Fixed bug in ... HAVING 'GROUP_FUNCTION'(xxx) IS [NOT] NULL.
- Fixed bug in truncation operator for boolean full-text search.
- Allow value of --user=# option for **mysqld** to be specified as a numeric user ID.
- Fixed a bug where SQL_CALC_ROWS returned an incorrect value when used with one table and ORDER BY and with InnoDB tables.
- Fixed that SELECT 0 LIMIT 0 doesn't hang thread.
- Fixed some problems with USE/IGNORE INDEX when using many keys with the same start column.
- Don't use table scan with BerkeleyDB and InnoDB tables when we can use an index that covers the whole row.
- Optimized InnoDB sort-buffer handling to take less memory.
- Fixed bug in multiple-table DELETE and InnoDB tables.
- Fixed problem with TRUNCATE and InnoDB tables that produced the error Can't execute the given command because you have active locked tables or an active transaction.
- Added NO_UNSIGNED_SUBTRACTION to the set of flags that may be specified with the --sql-mode option for **mysqld**. It disables unsigned arithmetic rules when it comes to subtraction. (This makes MySQL 4.0 behave more like 3.23 with UNSIGNED columns).
- The result returned for all bit functions (|, <<, ...) is now of type unsigned integer.
- Added detection of nan values in MyISAM to make it possible to repair tables with nan in float or double columns.
- Fixed new bug in **myisamchk** where it didn't correctly update number of ``parts" in the MyISAM index file.
- Changed to use **autoconf** 2.52 (from **autoconf** 2.13).
- Fixed optimization problem where the MySQL Server was in ``preparing" state for a long time when selecting from an empty table which had contained a lot of rows.

- Fixed bug in complicated join with `const` tables. This fix also improves performance a bit when referring to another table from a `const` table.
 - First pre-version of multiple-table `UPDATE` statement.
 - Fixed bug in multiple-table `DELETE`.
 - Fixed bug in `SELECT CONCAT(argument_list) ... GROUP BY 1`.
 - `INSERT ... SELECT` did a full rollback in case of an error. Fixed so that we only roll back the last statement in the current transaction.
 - Fixed bug with empty expression for boolean full-text search.
 - Fixed core dump bug in updating full-text key from/to `NULL`.
 - ODBC compatibility: Added `BIT_LENGTH()` function.
 - Fixed core dump bug in `GROUP BY BINARY` column.
 - Added support for `NULL` keys in `HEAP` tables.
 - Use index for `ORDER BY` in queries of type: `SELECT * FROM t WHERE key_part1=1 ORDER BY key_part1 DESC, key_part2 DESC`
 - Fixed bug in `FLUSH QUERY CACHE`.
 - Added `CAST()` and `CONVERT()` functions. The `CAST` and `CONVERT` functions are nearly identical and mainly useful when you want to create a column with a specific type in a `CREATE ... SELECT` statement. For more information, read Section 12.7, “Cast Functions and Operators”.
 - `CREATE ... SELECT` on `DATE` and `TIME` functions now create columns of the expected type.
 - Changed order in which keys are created in tables.
 - Added new columns `Null` and `Index_type` to `SHOW INDEX` output.
 - Added `--no-beep` and `--prompt` options to **mysql** command-line client.
 - New feature: management of user resources.
- ```
GRANT ... WITH MAX_QUERIES_PER_HOUR N1
 MAX_UPDATES_PER_HOUR N2
 MAX_CONNECTIONS_PER_HOUR N3;
```
- See Section 5.7.4, “Limiting Account Resources”.
- Added `mysql_secure_installation` to the `scripts/` directory.

## D.3.25. Changes in release 4.0.1 (23 Dec 2001)

- Added `system` command to **mysql**.
- Fixed bug when `HANDLER` was used with some unsupported table type.
- **mysqldump** now puts `ALTER TABLE tbl_name DISABLE KEYS` and `ALTER TABLE tbl_name ENABLE KEYS` in the sql dump.
- Added `mysql_fix_extensions` script.

- Fixed stack overrun problem with `LOAD DATA FROM MASTER` on OSF/1.
- Fixed shutdown problem on HP-UX.
- Added `DES_ENCRYPT()` and `DES_DECRYPT()` functions.
- Added `FLUSH DES_KEY_FILE` statement.
- Added `--des-key-file` option to **mysqld**.
- `HEX(str)` now returns the characters in `str` converted to hexadecimal.
- Fixed problem with `GRANT` when using `lower_case_table_names=1`.
- Changed `SELECT ... IN SHARE MODE` to `SELECT ... LOCK IN SHARE MODE` (as in MySQL 3.23).
- A new query cache to cache results from identical `SELECT` queries.
- Fixed core dump bug on 64-bit machines when it got an incorrect communication packet.
- `MATCH ... AGAINST(... IN BOOLEAN MODE)` can now work without `FULLTEXT` index.
- Fixed slave to replicate from 3.23 master.
- Miscellaneous replication fixes/cleanup.
- Got shutdown to work on Mac OS X.
- Added `myisam/ft_dump` utility for low-level inspection of `FULLTEXT` indexes.
- Fixed bug in `DELETE ... WHERE ... MATCH ...`.
- Added support for `MATCH ... AGAINST(... IN BOOLEAN MODE)`. **Note:** You must rebuild your tables with `ALTER TABLE tbl_name TYPE=MyISAM` to be able to use boolean full-text search.
- `LOCATE()` and `INSTR()` are now case sensitive if either argument is a binary string.
- Changed `RAND()` initialization so that `RAND(N)` and `RAND(N+1)` are more distinct.
- Fixed core dump bug in `UPDATE ... ORDER BY`.
- In 3.23, `INSERT INTO ... SELECT` always had `IGNORE` enabled. Now MySQL stops (and possibly rolls back) by default in case of an error unless you specify `IGNORE`.
- Ignore `DATA DIRECTORY` and `INDEX DIRECTORY` directives on Windows.
- Added boolean full-text search code. It should be considered early alpha.
- Extended `MODIFY` and `CHANGE` in `ALTER TABLE` to accept the `FIRST` and `AFTER` keywords.
- Indexes are now used with `ORDER BY` on a whole InnoDB table.

## D.3.26. Changes in release 4.0.0 (Oct 2001: Alpha)

- Added `--xml` option to **mysql** for producing XML output.
- Added full-text variables `ft_min_word_len`, `ft_max_word_len`, and `ft_max_word_len_for_sort` system variables.

- Added full-text variables `ft_min_word_len`, `ft_max_word_len`, and `ft_max_word_len_for_sort` variables to **myisamchk**.
- Added documentation for `libmysqld`, the embedded MySQL server library. Also added example programs (a **mysql** client and **mysqltest** test program) which use `libmysqld`.
- Removed all Gemini hooks from MySQL server.
- Removed `my_thread_init()` and `my_thread_end()` from `mysql_com.h`, and added `mysql_thread_init()` and `mysql_thread_end()` to `mysql.h`.
- Support for communication packets > 16MB. In 4.0.1 we extended MyISAM to be able to handle these.
- Secure connections (with SSL).
- Unsigned BIGINT constants now work. `MIN()` and `MAX()` now handle signed and unsigned BIGINT numbers correctly.
- New character set `latin1_de` which provides correct German sorting.
- `STRCMP()` now uses the current character set when doing comparisons, which means that the default comparison behavior now is case insensitive.
- `TRUNCATE TABLE` and `DELETE FROM tbl_name` are now separate functions. One bonus is that `DELETE FROM tbl_name` now returns the number of deleted rows, rather than zero.
- `DROP DATABASE` now executes a `DROP TABLE` on all tables in the database, which fixes a problem with InnoDB tables.
- Added support for UNION.
- Added support for multiple-table DELETE operations.
- A new HANDLER interface to MyISAM tables.
- Added support for INSERT on MERGE tables. Patch from Benjamin Pflugmann.
- Changed `WEEK(date, 0)` to match the calendar in the USA.
- `COUNT(DISTINCT)` is about 30% faster.
- Speed up all internal list handling.
- Speed up `IS NULL`, `ISNULL()` and some other internal primitives.
- Full-text index creation now is much faster.
- Tree-like cache to speed up bulk inserts and `myisam_bulk_insert_tree_size` variable.
- Searching on packed (CHAR/VARCHAR) keys is now much faster.
- Optimized queries of type: `SELECT DISTINCT * FROM tbl_name ORDER by key_part1 LIMIT row_count`.
- `SHOW CREATE TABLE` now shows all table attributes.
- `ORDER BY ... DESC` can now use keys.
- `LOAD DATA FROM MASTER` ``automatically" sets up a slave.
- Renamed **safe\_mysqld** to **mysqld\_safe** to make this name more in line with other MySQL scripts/commands.

- Added support for symbolic links to MyISAM tables. Symlink handling is now enabled by default for Windows.
- Added `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()`. This makes it possible to know how many rows a query would have returned without a `LIMIT` clause.
- Changed output format of `SHOW OPEN TABLES`.
- Allow `SELECT expression LIMIT ...`.
- Added the `IDENTITY` variable as a synonym for the `LAST_INSERT_ID` variable (like Sybase).
- Added `ORDER BY` syntax to `UPDATE` and `DELETE`.
- `SHOW INDEXES` is now a synonym for `SHOW INDEX`.
- Added `ALTER TABLE tbl_name DISABLE KEYS` and `ALTER TABLE tbl_name ENABLE KEYS` commands.
- Allow use of `IN` as a synonym for `FROM` in `SHOW` commands.
- Implemented "repair by sort" for `FULLTEXT` indexes. `REPAIR TABLE`, `ALTER TABLE`, and `OPTIMIZE TABLE` for tables with `FULLTEXT` indexes are now up to 100 times faster.
- Allow standard SQL syntax `X'hexadecimal-number'`.
- Cleaned up global lock handling for `FLUSH TABLES WITH READ LOCK`.
- Fixed problem with `DATETIME = constant` in `WHERE` optimization.
- Added `--master-data` and `--no-autocommit` options to **mysqldump**. (Thanks to Brian Aker for this.)
- Added script `mysql_explain_log.sh` to distribution. (Thanks to mobile.de).

## D.4. Changes in release 3.23.x (Recent; still supported)

Please note that since release 4.0 is now production level, only critical fixes are done in the 3.23 release series. You are recommended to upgrade when possible, to take advantage of all speed and feature improvements in 4.0. See Section 2.10.3, "Upgrading from Version 3.23 to 4.0".

The 3.23 release has several major features that are not present in previous versions. We have added three new table types:

- **MyISAM**  
A new `ISAM` library which is tuned for `SQL` and supports large files.
- **InnoDB**  
A transaction-safe storage engine that supports row level locking, and many Oracle-like features.
- **BerkeleyDB or BDB**  
Uses the Berkeley DB library from Sleepycat Software to implement transaction-safe tables.

Note that only `MyISAM` is available in the standard binary distribution.

The 3.23 release also includes support for database replication between a master and many slaves, full-text indexing, and much more.

All new features are being developed in the 4.1.x and 5.0.x versions. Only serious bugfixes are added to 3.23.

## D.4.1. Changes in release 3.23.59 (not released yet)

- Fixed an old bug in concurrent accesses to MERGE tables (even one MERGE table and MyISAM tables), that could've resulted in a crash or hang of the server. (Bug #2408 [<http://bugs.mysql.com/2408>], CAN-2004-0837 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0837>])
- Fixed incorrect destruction of expression which led to crash of server on complex AND/OR expressions if query was ignored (either by a replication server because of `--replicate-*-table` rules, or by any MySQL server because of a syntax error). (Bug #3969 [<http://bugs.mysql.com/3969>], Bug #4494 [<http://bugs.mysql.com/4494>])
- Fixed problem with parsing complex queries on 64-bit architectures. (Bug #4204 [<http://bugs.mysql.com/4204>])
- Fixed a symlink vulnerability in the `mysqlbug` script. (Bug #3284 [<http://bugs.mysql.com/3284>], CAN-2004-0381 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0381>])
- Fixed bug in privilege checking of ALTER TABLE RENAME. (Bug #3270 [<http://bugs.mysql.com/3270>], CAN-2004-0835 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0835>])
- Fixed bugs in ACOS( ), ASIN( ) (Bug #2338 [<http://bugs.mysql.com/2338>]) and in FLOOR( ) (Bug #3051 [<http://bugs.mysql.com/3051>]). The cause of the problem is an overly strong optimization done by `gcc` in this case.
- Fixed bug in INSERT ... SELECT statements where, if a NOT NULL column is assigned a value of NULL, the following columns in the row might be assigned a value of zero. (Bug #2012 [<http://bugs.mysql.com/2012>])
- If a query was ignored on the slave (because of `--replicate-ignore-table` and other similar rules), the slave still checked if the query got the same error code (0, no error) as on the master. So if the master had an error on the query (for example, "Duplicate entry" in a multiple-row insert), then the slave stopped and warned that the error codes didn't match. This is a backport of the fix for MySQL 4.0. (Bug #797 [<http://bugs.mysql.com/797>])
- **mysqlbinlog** now asks for a password at console when the `-p/--password` option is used with no argument. This is how the other clients (**mysqladmin**, **mysqldump**..) behave. Note that one now has to use **mysqlbinlog -p<my\_password>**; **mysqlbinlog -p <my\_password>** does not work anymore (in other words, put no space after `-p`). (Bug #1595 [<http://bugs.mysql.com/1595>])
- On some 64-bit machines (some HP-UX and Solaris machines), a slave installed with the 64-bit MySQL binary could not connect to its master (it connected to itself instead). (Bug #1256 [<http://bugs.mysql.com/1256>], Bug #1381 [<http://bugs.mysql.com/1381>])
- Fixed a Windows-specific bug present since MySQL 3.23.57 and 3.23.58 that caused Windows slaves to crash when they started replication if a `master.info` file existed. (Bug #1720 [<http://bugs.mysql.com/1720>])
- Fixed bug in ALTER TABLE RENAME, when rename to the table with the same name in another database silently dropped destination table if it existed. (Bug #2628 [<http://bugs.mysql.com/2628>])
- Fixed potential memory overrun in `mysql_real_connect()` (which required a comprom-

ised DNS server and certain operating systems). (Bug #4017 [<http://bugs.mysql.com/4017>], CAN-2004-0836 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2004-0836>])

## D.4.2. Changes in release 3.23.58 (11 Sep 2003)

- Fixed buffer overflow in password handling which could potentially be exploited by MySQL users with ALTER privilege on the `mysql.user` table to execute random code or to gain shell access with the UID of the `mysqld` process (thanks to Jedi/Sector One for spotting and reporting this bug).
- **mysqldump** now correctly quotes all identifiers when communicating with the server. This assures that during the dump process, **mysqldump** never sends queries to the server that result in a syntax error. This problem is **not** related to the **mysqldump** program's output, which was not changed. (Bug #1148 [<http://bugs.mysql.com/1148>])
- Fixed table/column grant handling: The proper sort order (from most specific to less specific, see Section 5.6.6, "Access Control, Stage 2: Request Verification") was not honored. (Bug #928 [<http://bugs.mysql.com/928>])
- Fixed overflow bug in MyISAM and ISAM when a row is updated in a table with a large number of columns and at least one BLOB/TEXT column.
- Fixed MySQL so that field length (in C API) for the second column in SHOW CREATE TABLE is always larger than the data length. The only known application that was affected by the old behavior was Borland dbExpress, which truncated the output from the command. (Bug #1064 [<http://bugs.mysql.com/1064>])
- Fixed ISAM bug in MAX( ) optimization.
- Fixed Unknown error when doing ORDER BY on reference table which was used with NULL value on NOT NULL column. (Bug #479 [<http://bugs.mysql.com/479>])

## D.4.3. Changes in release 3.23.57 (06 Jun 2003)

- Fixed problem in alarm handling that could cause problems when getting a packet that is too large.
- Fixed problem when installing MySQL as a service on Windows when two arguments were specified to **mysqld** (option file group name and service name).
- Fixed `kill pid-of-mysqld` to work on Mac OS X.
- SHOW TABLE STATUS displayed incorrect Row\_format value for tables that have been compressed with **myisampack**. (Bug #427 [<http://bugs.mysql.com/427>])
- SHOW VARIABLES LIKE 'innodb\_data\_file\_path' displayed only the name of the first data file. (Bug #468 [<http://bugs.mysql.com/468>])
- Fixed security problem where **mysqld** didn't allow one to UPDATE rows in a table even if one had a global UPDATE privilege and a database SELECT privilege.
- Fixed a security problem with SELECT and wildcarded select list, when user only had partial column SELECT privileges on the table.
- Fixed unlikely problem in optimizing WHERE clause with a constant expression such as in WHERE 1 AND (a=1 AND b=1).
- Fixed problem on IA-64 with timestamps that caused **mysqlbinlog** to fail.

- The default option for `innodb_flush_log_at_trx_commit` was changed from 0 to 1 to make InnoDB tables ACID by default. See Section 15.5, “InnoDB Startup Options”.
- Fixed problem with too many allocated alarms on slave when connecting to master many times (normally not a very critical error).
- Fixed a bug in replication of temporary tables. (Bug #183 [<http://bugs.mysql.com/183>])
- Fixed 64-bit bug that affected at least AMD hammer systems.
- Fixed a bug when doing `LOAD DATA INFILE IGNORE`: When reading the binary log, **mysqlbinlog** and the replication code read `REPLACE` instead of `IGNORE`. This could make the slave's table become different from the master's table. (Bug #218 [<http://bugs.mysql.com/218>])
- Fixed overflow bug in MyISAM when a row is inserted into a table with a large number of columns and at least one BLOB/TEXT column. Bug was caused by incorrect calculation of the needed buffer to pack data.
- The binary log was not locked during `TRUNCATE tbl_name` or `DELETE FROM tbl_name` statements, which could cause an `INSERT` to `tbl_name` to be written to the log before the `TRUNCATE` or `DELETE` statements.
- Fixed rare bug in `UPDATE` of InnoDB tables where one row could be updated multiple times.
- Produce an error for empty table and column names.
- Changed `PROCEDURE ANALYSE ( )` to report `DATE` instead of `NEWDATE`.
- Changed `PROCEDURE ANALYSE ( # )` to restrict the number of values in an ENUM column to # also for string values.
- **mysqldump** no longer silently deletes the binary logs when invoked with the `--master-data` or `--first-slave` option; while this behavior was convenient for some users, others may suffer from it. Now you must explicitly ask for binary logs to be deleted by using the new `--delete-master-logs` option.
- Fixed a bug in **mysqldump** when it was invoked with the `--master-data` option: The `CHANGE MASTER TO` statements that were appended to the SQL dump had incorrect coordinates. (Bug #159 [<http://bugs.mysql.com/159>])

#### D.4.4. Changes in release 3.23.56 (13 Mar 2003)

- Fixed **mysqld** crash on extremely small values of `sort_buffer` variable.
- Fixed a bug in privilege system for `GRANT UPDATE` on the column level.
- Fixed a rare bug when using a date in `HAVING` with `GROUP BY`.
- Fixed checking of random part of `WHERE` clause. (Bug #142 [<http://bugs.mysql.com/142>])
- Fixed MySQL (and **myisamchk**) crash on artificially corrupted `.MYI` files.
- Security enhancement: **mysqld** no longer reads options from world-writable config files. (CAN-2003-0150 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2003-0150>])
- Security enhancement: **mysqld** and **safe\_mysqld** now use only the first `--user` option specified on the command line. Normally this comes from `/etc/my.cnf`. (CAN-2003-0150 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2003-0150>])
- Security enhancement: Don't allow `BACKUP TABLE` to overwrite existing files.

- Fixed unlikely deadlock bug when one thread did a `LOCK TABLE` and another thread did a `DROP TABLE`. In this case one could do a `KILL` on one of the threads to resolve the deadlock.
- `LOAD DATA INFILE` was not replicated by slave if `replicate_*_table` was set on the slave.
- Fixed a bug in handling `CHAR(0)` columns that could cause incorrect results from the query.
- Fixed a bug in `SHOW VARIABLES` on 64-bit platforms. The bug was caused by incorrect declaration of variable `server_id`.
- The `Comment` column in `SHOW TABLE STATUS` now reports that it can contain `NULL` values (which is the case for a crashed `.frm` file).
- Fixed the `rpl_rotate_logs` test to not fail on certain platforms (such as Mac OS X) due to a too-long file name (changed `slave-master-info.opt` to `.slave-mi`).
- Fixed a problem with `BLOB NOT NULL` columns used with `IS NULL`.
- Fixed bug in `MAX()` optimization in `MERGE` tables.
- Better `RAND()` initialization for new connections.
- Fixed bug with connect timeout. This bug was manifested on OS's with `poll()` system call, which resulted in timeout the value specified as it was executed in both `select()` and `poll()`.
- Fixed bug in `SELECT * FROM table WHERE datetime1 IS NULL OR datetime2 IS NULL`.
- Fixed bug in using aggregate functions as argument for `INTERVAL`, `CASE`, `FIELD`, `CONCAT_WS`, `ELT` and `MAKE_SET` functions.
- When running with `--lower-case-table-names=1` (default on Windows) and you had tables or databases with mixed case on disk, then executing `SHOW TABLE STATUS` followed with `DROP DATABASE` or `DROP TABLE` could fail with `Errcode 13`.
- Fixed bug in logging to binary log (which affects replication) a query that inserts a `NULL` in an `auto_increment` field and also uses `LAST_INSERT_ID()`.
- Fixed bug in `mysqladmin --relative`.
- On some 64-bit systems, `show status` reported a strange number for `Open_files` and `Open_streams`.

## D.4.5. Changes in release 3.23.55 (23 Jan 2003)

- Fixed double `free'd` pointer bug in `mysql_change_user()` handling, that enabled a specially hacked version of MySQL client to crash `mysqld`. **Note** that you must log in to the server by using a valid user account to be able to exploit this bug. (CVE-2003-0073 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2003-0073>])
- Fixed bug with the `--slow-log` when logging an administrator command (like `FLUSH TABLES`).
- Fixed bug in `GROUP BY` when used on `BLOB` column with `NULL` values.
- Fixed a bug in handling `NULL` values in `CASE ... WHEN ...`.
- Bugfix for `--chroot` (see Section D.4.6, “Changes in release 3.23.54 (05 Dec 2002)”) is reverted. Unfortunately, there is no way to make it to work, without introducing backward-in-

compatible changes in `my.cnf`. Those who need `--chroot` functionality, should upgrade to MySQL 4.0. (The fix in the 4.0 branch did not break backward-compatibility).

- Make `--lower-case-table-names` default on Mac OS X as the default filesystem (HFS+) is case insensitive.
- Fixed a bug in `scripts/mysqld_safe.sh` in `NOHUP_NICENESS` testing.
- Transactions in `AUTOCOMMIT=0` mode didn't rotate binary log.
- Fixed a bug in `scripts/make_binary_distribution` that resulted in a remaining `@HOSTNAME@` variable instead of replacing it with the correct path to the `hostname` binary.
- Fixed a very unlikely bug that could cause `SHOW PROCESSLIST` to core dump in `pthread_mutex_unlock()` if a new thread was connecting.
- Forbid `SLAVE STOP` if the thread executing the query has locked tables. This removes a possible deadlock situation.

## D.4.6. Changes in release 3.23.54 (05 Dec 2002)

- Fixed a bug, that allowed to crash `mysqld` with a specially crafted packet. (CVE-2002-1373 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1373>])
- Fixed a rare crash (double `free`'d pointer) when altering a temporary table.
- Fixed buffer overrun in `libmysqlclient` library that allowed malicious MySQL server to crash the client application. (CAN-2002-1376 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2002-1376>])
- Fixed security-related bug in `mysql_change_user()` handling. All users are strongly recommended to upgrade to the version 3.23.54. (CVE-2002-1374 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1374>], CVE-2002-1375 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-1375>])
- Fixed bug that prevented `--chroot` command-line option of `mysqld` from working.
- Fixed bug that made `OPTIMIZE TABLE` to corrupt the table under some rare circumstances.
- Fixed `mysqlcheck` so it can deal with table names containing dashes.
- Fixed shutdown problem on Mac OS X.
- Fixed bug with comparing an indexed `NULL` field with `<=> NULL`.
- Fixed bug that caused `IGNORE INDEX` and `USE INDEX` sometimes to be ignored.
- Fixed rare core dump problem in complicated `GROUP BY` queries that didn't return any result.
- Fixed a bug where `MATCH ... AGAINST ( ) >=0` was treated as if it was `>`.
- Fixed core dump in `SHOW PROCESSLIST` when running with an active slave (unlikely timing bug).
- Make it possible to use multiple MySQL servers on Windows (code backported from 4.0.2).
- One can create `TEMPORARY MERGE` tables now.
- Fixed that `--core-file` works on Linux (at least on kernel 2.4.18).
- Fixed a problem with `BDB` and `ALTER TABLE`.

- Fixed reference to freed memory when doing complicated `GROUP BY ... ORDER BY` queries. Symptom was that **mysqld** died in function `send_fields`.
- Allocate heap rows in smaller blocks to get better memory usage.
- Fixed memory allocation bug when storing BLOB values in internal temporary tables used for some (unlikely) `GROUP BY` queries.
- Fixed a bug in key optimizing handling where the expression `WHERE col_name = key_col_name` was calculated as true for NULL values.
- Fixed core dump bug when doing `LEFT JOIN ... WHERE key_column=NULL`.
- Fixed MyISAM crash when using dynamic-row tables with huge numbers of packed fields.
- Updated source tree to be built using **automake** 1.5 and **libtool** 1.4.

## D.4.7. Changes in release 3.23.53 (09 Oct 2002)

- Fixed crash when `SHOW INNODB STATUS` was used and `skip-innodb` was defined.
- Fixed possible memory corruption bug in binary log file handling when slave rotated the logs (only affected 3.23, not 4.0).
- Fixed problem in `LOCK TABLES` on Windows when one connects to a database that contains uppercase letters.
- Fixed that `--skip-show-database` doesn't reset the `--port` option.
- Small fix in **safe\_mysqld** for some shells.
- Fixed that `FLUSH STATUS` doesn't reset `delayed_insert_threads`.
- Fixed core dump bug when using the `BINARY` cast on a NULL value.
- Fixed race condition when someone did a `GRANT` at the same time a new user logged in or did a `USE database`.
- Fixed bug in `ALTER TABLE` and `RENAME TABLE` when running with `-O lower_case_table_names=1` (typically on Windows) when giving the table name in uppercase.
- Fixed that `-O lower_case_table_names=1` also converts database names to lowercase.
- Fixed unlikely core dump with `SELECT ... ORDER BY ... LIMIT`.
- Changed `AND/OR` to report that they can return NULL. This fixes a bug in `GROUP BY` on `AND/OR` expressions that return NULL.
- Fixed a bug that `OPTIMIZE TABLE` of locked and modified MyISAM table, reported table corruption.
- Fixed a BDB-related `ALTER TABLE` bug with dropping a column and shutting down immediately thereafter.
- Fixed problem with `configure ... --localstatedir=...`
- Fixed problem with `UNSIGNED BIGINT` on AIX (again).
- Fixed bug in `pthread_mutex_trylock()` on HP-UX 11.0.
- Multi-threaded stress tests for InnoDB.

## D.4.8. Changes in release 3.23.52 (14 Aug 2002)

- Wrap `BEGIN/COMMIT` around transaction in the binary log. This makes replication honor transactions.
- Fixed security bug when having an empty database name in the user `.db` table.
- Changed initialization of `RAND()` to make it less predicatable.
- Fixed problem with `GROUP BY` on result with expression that created a `BLOB` field.
- Fixed problem with `GROUP BY` on columns that have `NULL` values. To solve this we now create an `MyISAM` temporary table when doing a `GROUP BY` on a possible `NULL` item. From MySQL 4.0.5 we can use in memory `HEAP` tables for this case.
- Fixed problem with privilege tables when downgrading from 4.0.2 to 3.23.
- Fixed thread bug in `SLAVE START`, `SLAVE STOP` and automatic repair of `MyISAM` tables that could cause table cache to be corrupted.
- Fixed possible thread related key-cache-corruption problem with `OPTIMIZE TABLE` and `REPAIR TABLE`.
- Added name of 'administrator command' logs.
- Fixed bug with creating an auto-increment value on second part of a `UNIQUE()` key where first part could contain `NULL` values.
- Don't write slave-timeout reconnects to the error log.
- Fixed bug with slave net read timeouting
- Fixed a core-dump bug with `MERGE` tables and `MAX()` function.
- Fixed bug in `ALTER TABLE` with `BDB` tables.
- Fixed bug when logging `LOAD DATA INFILE` to binary log with no active database.
- Fixed a bug in range optimizer (causing crashes).
- Fixed possible problem in replication when doing `DROP DATABASE` on a database with `InnoDB` tables.
- Fixed `mysql_info()` to return 0 for `Duplicates` value when using `INSERT DELAYED IGNORE`.
- Added `-DHAVE_BROKEN_REALPATH` to the Mac OS X (darwin) compile options in `configure.in` to fix a failure under high load.

## D.4.9. Changes in release 3.23.51 (31 May 2002)

- Fix bug with closing tags missing slash for `mysqldump` XML output.
- Remove endspace from `ENUM` values. (This fixed a problem with `SHOW CREATE TABLE`.)
- Fixed bug in `CONCAT_WS()` that cut the result.
- Changed name of server variables `Com_show_master_stat` to `Com_show_master_status` and `Com_show_slave_stat` to `Com_show_slave_status`.

- Changed handling of `gethostbyname()` to make the client library thread-safe even if `gethostbyname_r` doesn't exist.
- Fixed core-dump problem when giving a wrong password string to `GRANT`.
- Fixed bug in `DROP DATABASE` with symlinked directory.
- Fixed optimization problem with `DATETIME` and value outside `DATETIME` range.
- Removed Sleepycat's BDB doc files from the source tree, as they're not needed (MySQL covers BDB in its own documentation).
- Fixed MIT-pthreads to compile with `glibc 2.2` (needed for **make dist**).
- Fixed the `FLOAT(X+1,X)` is not converted to `FLOAT(X+2,X)`. (This also affected `DECIMAL`, `DOUBLE` and `REAL` types)
- Fixed the result from `IF()` is case in-sensitive if the second and third arguments are case sensitive.
- Fixed core dump problem on OSF/1 in `gethostbyname_r`.
- Fixed that underflowed decimal fields are not zero filled.
- If we get an overflow when inserting `'+11111'` for `DECIMAL(5,0) UNSIGNED` columns, we just drop the sign.
- Fixed optimization bug with `ISNULL(expression_which_cannot_be_null)` and `ISNULL(constant_expression)`.
- Fixed host lookup bug in the `glibc` library that we used with the 3.23.50 Linux-x86 binaries.

## D.4.10. Changes in release 3.23.50 (21 Apr 2002)

- Fixed buffer overflow problem if someone specified a too-long `datadir` parameter to **mysqld**. (CVE-2002-0969 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2002-0969>])
- Add missing `<row>` tags for **mysqldump** XML output.
- Fixed problem with `crash-me` and **gcc** 3.0.4.
- Fixed that `@@unknown_variable` doesn't hang server.
- Added `@@VERSION` as a synonym for `VERSION()`.
- `SHOW VARIABLES LIKE 'xxx'` is now case-insensitive.
- Fixed timeout for `GET_LOCK()` on HP-UX with DCE threads.
- Fixed memory allocation bug in the `glibc` library used to build Linux binaries, which caused **mysqld** to die in `free()`.
- Fixed `SIGINT` and `SIGQUIT` problems in **mysql**.
- Fixed bug in character table converts when used with big (larger than 64KB) strings.
- InnoDB now retains foreign key constraints through `ALTER TABLE` and `CREATE/DROP INDEX`.
- InnoDB now allows foreign key constraints to be added through the `ALTER TABLE` syntax.
- InnoDB tables can now be set to automatically grow in size (`autoextend`).

- Our Linux RPMS and binaries are now compiled with **gcc** 3.0.4, which should make them a bit faster.
- Fixed some buffer overflow problems when reading startup parameters.
- Because of problems on shutdown we have now disabled named pipes on Windows by default. One can enable named pipes by starting **mysqld** with `--enable-named-pipe`.
- Fixed bug when using `WHERE key_column = 'J' or key_column='j'`.
- Fixed core-dump bug when using `--log-bin` with `LOAD DATA INFILE` without an active database.
- Fixed bug in `RENAME TABLE` when used with `lower_case_table_names=1` (default on Windows).
- Fixed unlikely core-dump bug when using `DROP TABLE` on a table that was in use by a thread that also used queries on only temporary tables.
- Fixed problem with `SHOW CREATE TABLE` and `PRIMARY KEY` when using 32 indexes.
- Fixed that one can use `SET PASSWORD` for the anonymous user.
- Fixed core dump bug when reading client groups from option files using `mysql_options()`.
- Memory leak (16 bytes per every **corrupted** table) closed.
- Fixed binary builds to use `--enable-local-infile`.
- Update source to work with new version of **bison**.
- Updated shell scripts to now agree with new POSIX standard.
- Fixed bug where `DATE_FORMAT()` returned empty string when used with `GROUP BY`.

## D.4.11. Changes in release 3.23.49 (14 Feb 2002)

- For a `MERGE` table, `DELETE FROM merge_table` used without a `WHERE` clause no longer clears the mapping for the table by emptying the `.MRG` file. Instead, it deletes records from the mapped tables.
- Don't give warning for a statement that is only a comment; this is needed for **mysqldump -disable-keys** to work.
- Fixed unlikely caching bug when doing a join without keys. In this case, the last used field for a table always returned `NULL`.
- Added options to make `LOAD DATA LOCAL INFILE` more secure.
- MySQL binary release 3.23.48 for Linux contained a new `glibc` library, which has serious problems under high load and Red Hat 7.2. The 3.23.49 binary release doesn't have this problem.
- Fixed shutdown problem on NT.

## D.4.12. Changes in release 3.23.48 (07 Feb 2002)

- Added `--xml` option to **mysqldump** for producing XML output.

- Changed to use **autoconf** 2.52 (from **autoconf** 2.13)
- Fixed bug in complicated join with `const` tables.
- Added internal safety checks for InnoDB.
- Some InnoDB variables were always shown in `SHOW VARIABLES` as `OFF` on high-byte-first systems (like SPARC).
- Fixed problem with one thread using an InnoDB table and another thread doing an `ALTER TABLE` on the same table. Before that, **mysqld** could crash with an assertion failure in `row0row.c`, line 474.
- Tuned the InnoDB SQL optimizer to favor index searches more often over table scans.
- Fixed a performance problem with InnoDB tables when several large `SELECT` queries are run concurrently on a multiprocessor Linux computer. Large CPU-bound `SELECT` queries now also generally run faster on all platforms.
- If MySQL binary logging is used, InnoDB now prints after crash recovery the latest MySQL binary log name and the offset InnoDB was able to recover to. This is useful, for example, when resynchronizing a master and a slave database in replication.
- Added better error messages to help in installation problems of InnoDB tables.
- It is now possible to recover MySQL temporary tables that have become orphaned inside the InnoDB tablespace.
- InnoDB now prevents a `FOREIGN KEY` declaration where the signedness is not the same in the referencing and referenced integer columns.
- Calling `SHOW CREATE TABLE` or `SHOW TABLE STATUS` could cause memory corruption and make **mysqld** crash. Especially at risk was **mysqldump**, because it frequently calls `SHOW CREATE TABLE`.
- If inserts to several tables containing an `AUTO_INCREMENT` column were wrapped inside one `LOCK TABLES`, InnoDB asserted in `lock0lock.c`.
- In 3.23.47 we allowed several `NULL` values in a `UNIQUE` secondary index for an InnoDB table. But `CHECK TABLE` was not relaxed: it reports the table as corrupt. `CHECK TABLE` no longer complains in this situation.
- `SHOW GRANTS` now shows `REFERENCES` instead of `REFERENCE`.

## D.4.13. Changes in release 3.23.47 (27 Dec 2001)

- Fixed bug when using the following construct: `SELECT ... WHERE key=@var_name OR key=@var_name2`
- Restrict InnoDB keys to 500 bytes.
- InnoDB now supports `NULL` in keys.
- Fixed shutdown problem on HP-UX. (Introduced in 3.23.46)
- Fixed core dump bug in replication when using `SELECT RELEASE_LOCK()`.
- Added new statement: `DO expr[,expr]...`
- Added `slave-skip-errors` option.

- Added statistics variables for all MySQL commands. (`SHOW STATUS` is now much longer.)
- Fixed default values for InnoDB tables.
- Fixed that `GROUP BY expr DESC` works.
- Fixed bug when using `t1 LEFT JOIN t2 ON t2.key=constant`.
- `mysql_config` now also works with binary (relocated) distributions.

## D.4.14. Changes in release 3.23.46 (29 Nov 2001)

- Fixed problem with aliased temporary table replication.
- InnoDB and BDB tables now use index when doing an `ORDER BY` on the whole table.
- Fixed bug where one got an empty set instead of a DEADLOCK error when using BDB tables.
- One can now kill `ANALYZE TABLE`, `REPAIR TABLE`, and `OPTIMIZE TABLE` when the thread is waiting to get a lock on the table.
- Fixed race condition in `ANALYZE TABLE`.
- Fixed bug when joining with caching (unlikely to happen).
- Fixed race condition when using the binary log and `INSERT DELAYED` which could cause the binary log to have rows that were not yet written to MyISAM tables.
- Changed caching of binary log to make replication slightly faster.
- Fixed bug in replication on Mac OS X.

## D.4.15. Changes in release 3.23.45 (22 Nov 2001)

- (`UPDATE|DELETE`) `...WHERE MATCH` bugfix.
- shutdown should now work on Darwin (Mac OS X).
- Fixed core dump when repairing corrupted packed MyISAM files.
- `--core-file` now works on Solaris.
- Fix a bug which could cause InnoDB to complain if it cannot find free blocks from the buffer cache during recovery.
- Fixed bug in InnoDB insert buffer B-tree handling that could cause crashes.
- Fixed bug in InnoDB lock timeout handling.
- Fixed core dump bug in `ALTER TABLE` on a TEMPORARY InnoDB table.
- Fixed bug in `OPTIMIZE TABLE` that reset index cardinality if it was up to date.
- Fixed problem with `t1 LEFT JOIN t2 ... WHERE t2.date_column IS NULL` when `date_column` was declared as `NOT NULL`.
- Fixed bug with BDB tables and keys on BLOB columns.
- Fixed bug in MERGE tables on OS with 32-bit file pointers.

- Fixed bug in `TIME_TO_SEC()` when using negative values.

## D.4.16. Changes in release 3.23.44 (31 Oct 2001)

- Fixed `Rows_examined` count in slow query log.
- Fixed bug when using a reference to an `AVG()` column in `HAVING`.
- Fixed that date functions that require correct dates, like `DAYOFYEAR(column)`, return `NULL` for `0000-00-00` dates.
- Fixed bug in const-propagation when comparing columns of different types. (`SELECT * FROM date_col="2001-01-01" and date_col=time_col`)
- Fixed bug that caused error message `Can't write, because of unique constraint with some GROUP BY queries`.
- Fixed problem with `sjis` character strings used within quoted table names.
- Fixed core dump when using `CREATE ... FULLTEXT` keys with other storage engines than `MyISAM`.
- Don't use `signal()` on Windows because this appears to not be 100% reliable.
- Fixed bug when doing `WHERE col_name=NULL` on an indexed column that had `NULL` values.
- Fixed bug when doing `LEFT JOIN ... ON (col_name = constant) WHERE col_name = constant`.
- When using replications, aborted queries that contained `%` could cause a core dump.
- `TCP_NODELAY` was not used on some systems. (Speed problem.)
- Applied portability fixes for OS/2. (Patch by Yuri Dario.)

The following changes are for `InnoDB` tables:

- Add missing `InnoDB` variables to `SHOW VARIABLES`.
- Foreign key checking is now done for `InnoDB` tables.
- `DROP DATABASE` now works also for `InnoDB` tables.
- `InnoDB` now supports data files and raw disk partitions bigger than 4GB on those operating systems that have big files.
- `InnoDB` calculates better table cardinality estimates for the MySQL optimizer.
- Accent characters in the default character set `latin1` are ordered according to the MySQL ordering.

Note: If you are using `latin1` and have inserted characters whose code is greater than 127 into an indexed `CHAR` column, you should run `CHECK TABLE` on your table when you upgrade to 3.23.44, and drop and reimport the table if `CHECK TABLE` reports an error!

- A new `my.cnf` parameter, `innodb_thread_concurrency`, helps in performance tuning in heavily concurrent environments.
- A new `my.cnf` parameter, `innodb_fast_shutdown`, speeds up server shutdown.

- A new `my.cnf` parameter, `innodb_force_recovery`, helps to save your data in case the disk image of the database becomes corrupt.
- `innodb_monitor` has been improved and a new `innodb_table_monitor` added.
- Increased maximum key length from 500 to 7000 bytes.
- Fixed a bug in replication of `AUTO_INCREMENT` columns with multiple-line inserts.
- Fixed a bug when the case of letters changes in an update of an indexed secondary column.
- Fixed a hang when there are more than 24 data files.
- Fixed a crash when `MAX(col)` is selected from an empty table, and `col` is not the first column in a multi-column index.
- Fixed a bug in purge which could cause crashes.

## D.4.17. Changes in release 3.23.43 (04 Oct 2001)

- Fixed a bug in `INSERT DELAYED` and `FLUSH TABLES` introduced in 3.23.42.
- Fixed unlikely bug, which returned non-matching rows, in `SELECT` with many tables and multi-column indexes and 'range' type.
- Fixed an unlikely core dump bug when doing `EXPLAIN SELECT` when using many tables and `ORDER BY`.
- Fixed bug in `LOAD DATA FROM MASTER` when using table with `CHECKSUM=1`.
- Added unique error message when a `DEADLOCK` occurs during a transaction with BDB tables.
- Fixed problem with BDB tables and `UNIQUE` columns defined as `NULL`.
- Fixed problem with **myisampack** when using pre-space filled `CHAR` columns.
- Applied patch from Yuri Dario for OS/2.
- Fixed bug in `--safe-user-create`.

## D.4.18. Changes in release 3.23.42 (08 Sep 2001)

- Fixed problem when using `LOCK TABLES` and BDB tables.
- Fixed problem with `REPAIR TABLE` on MyISAM tables with row lengths in the range from 65517 to 65520 bytes.
- Fixed rare hang when doing **mysqladmin shutdown** when there was a lot of activity in other threads.
- Fixed problem with `INSERT DELAYED` where delayed thread could be hanging on upgrading locks for no apparent reason.
- Fixed problem with **myisampack** and `BLOB`.
- Fixed problem when one edited `.MRG` tables by hand. (Patch from Benjamin Pflugmann).
- Enforce that all tables in a `MERGE` table come from the same database.

- Fixed bug with `LOAD DATA INFILE` and transactional tables.
- Fix bug when using `INSERT DELAYED` with wrong column definition.
- Fixed core dump during `REPAIR TABLE` of some particularly broken tables.
- Fixed bug in InnoDB and `AUTO_INCREMENT` columns.
- Fixed bug in InnoDB and `RENAME TABLE` columns.
- Fixed critical bug in InnoDB and BLOB columns. If you have used BLOB columns larger than 8000 bytes in an InnoDB table, it is necessary to dump the table with **mysqldump**, drop it and restore it from the dump.
- Applied large patch for OS/2 from Yuri Dario.
- Fixed problem with InnoDB when one could get the error `Can't execute the given command . . . even when no transaction was active`.
- Applied some minor fixes that concern Gemini.
- Use real arithmetic operations even in integer context if not all arguments are integers. (Fixes uncommon bug in some integer contexts).
- Don't force everything to lowercase on Windows. (To fix problem with Windows and `ALTER TABLE`.) Now `--lower_case_table_names` also works on Unix.
- Fixed that automatic rollback is done when thread end doesn't lock other threads.

## D.4.19. Changes in release 3.23.41 (11 Aug 2001)

- Added `--sql-mode=value[,value[,value]]` option to **mysqld**. See Section 5.3.1, “**mysqld** Command-Line Options”.
- Fixed possible problem with shutdown on Solaris where the `.pid` file wasn't deleted.
- InnoDB now supports < 4GB rows. The former limit was 8000 bytes.
- The `doublewrite` file flush method is used in InnoDB. It reduces the need for Unix `fsync()` calls to a fraction and improves performance on most Unix flavors.
- You can now use the InnoDB Monitor to print a lot of InnoDB state information, including locks, to the standard output. This is useful in performance tuning.
- Several bugs which could cause hangs in InnoDB have been fixed.
- Split `record_buffer` to `record_buffer` and `record_rnd_buffer`. To make things compatible to previous MySQL versions, if `record_rnd_buffer` is not set, then it takes the value of `record_buffer`.
- Fixed optimizing bug in `ORDER BY` where some `ORDER BY` parts were wrongly removed.
- Fixed overflow bug with `ALTER TABLE` and `MERGE` tables.
- Added prototypes for `my_thread_init()` and `my_thread_end()` to `mysql_com.h`
- Added `--safe-user-create` option to **mysqld**.
- Fixed bug in `SELECT DISTINCT . . . HAVING` that caused error message `Can't find record in #...`

## D.4.20. Changes in release 3.23.40 (18 Jul 2001)

- Fixed problem with `--low-priority-updates` and `INSERT` statements.
- Fixed bug in slave thread when under some rare circumstances it could get 22 bytes ahead on the offset in the master.
- Added `slave_net_timeout` for replication.
- Fixed problem with `UPDATE` and BDB tables.
- Fixed hard bug in BDB tables when using key parts.
- Fixed problem when using `GRANT FILE ON database.* ...`; previously we added the `DROP` privilege for the database.
- Fixed `DELETE FROM tbl_name ... LIMIT 0` and `UPDATE FROM tbl_name ... LIMIT 0`, which acted as though the `LIMIT` clause was not present (they deleted or updated all selected rows).
- `CHECK TABLE` now checks whether an `AUTO_INCREMENT` column contains the value 0.
- Sending a `SIGHUP` to **mysqld** now only flushes the logs, but does not reset the replication.
- Fixed parser to allow floats of type `1.0e1` (no sign after `e`).
- Option `--force` to **myisamchk** now also updates states.
- Added option `--warnings` to **mysqld**. Now **mysqld** prints the error `Aborted connection` only if this option is used.
- Fixed problem with `SHOW CREATE TABLE` when you didn't have a `PRIMARY KEY`.
- Properly fixed the rename of `innodb_unix_file_flush_method` variable to `innodb_flush_method`.
- Fixed bug when converting `BIGINT UNSIGNED` to `DOUBLE`. This caused a problem when doing comparisons with `BIGINT` values outside of the signed range.
- Fixed bug in BDB tables when querying empty tables.
- Fixed a bug when using `COUNT(DISTINCT)` with `LEFT JOIN` and there weren't any matching rows.
- Removed all documentation referring to the `GEMINI` table type. `GEMINI` is not released under an Open Source license.

## D.4.21. Changes in release 3.23.39 (12 Jun 2001)

- The `AUTO_INCREMENT` sequence wasn't reset when dropping and adding an `AUTO_INCREMENT` column.
- `CREATE ... SELECT` now creates non-unique indexes delayed.
- Fixed problem where `LOCK TABLES tbl_name READ` followed by `FLUSH TABLES` put an exclusive lock on the table.
- `REAL @variable` values were represented with only 2 digits when converted to strings.
- Fixed problem that client ``hung" when `LOAD TABLE FROM MASTER` failed.

- **myisamchk --fast --force** no longer repairs tables that only had the open count wrong.
- Added functions to handle symbolic links to make life easier in 4.0.
- We are now using the `-lcma` thread library on HP-UX 10.20 so that MySQL is more stable on HP-UX.
- Fixed problem with `IF( )` and number of decimals in the result.
- Fixed date-part extraction functions to work with dates where day and/or month is 0.
- Extended argument length in option files from 256 to 512 chars.
- Fixed problem with shutdown when `INSERT DELAYED` was waiting for a `LOCK TABLE`.
- Fixed core dump bug in InnoDB when tablespace was full.
- Fixed problem with `MERGE` tables and big tables (larger than 4GB) when using `ORDER BY`.

## D.4.22. Changes in release 3.23.38 (09 May 2001)

- Fixed a bug when `SELECT` from `MERGE` table sometimes results in incorrectly ordered rows.
- Fixed a bug in `REPLACE( )` when using the `ujis` character set.
- Applied Sleepycat BDB patches 3.2.9.1 and 3.2.9.2.
- Added `--skip-stack-trace` option to **mysqld**.
- `CREATE TEMPORARY` now works with InnoDB tables.
- InnoDB now promotes sub keys to whole keys.
- Added option `CONCURRENT` to `LOAD DATA`.
- Better error message when slave `max_allowed_packet` is too low to read a very long log event from the master.
- Fixed bug when too many rows were removed when using `SELECT DISTINCT ... HAVING`.
- `SHOW CREATE TABLE` now returns `TEMPORARY` for temporary tables.
- Added `Rows_examined` to slow query log.
- Fixed problems with function returning empty string when used together with a group function and a `WHERE` that didn't match any rows.
- New program **mysqlcheck**.
- Added database name to output for administrative commands like `CHECK TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`.
- Lots of portability fixes for InnoDB.
- Changed optimizer so that queries like `SELECT * FROM tbl_name, tbl_name2 ... ORDER BY key_part1 LIMIT row_count` use an index on `key_part1` instead of filesort.
- Fixed bug when doing `LOCK TABLE to_table WRITE,...; INSERT INTO to_table... SELECT ...` when `to_table` was empty.

- Fixed bug with `LOCK TABLE` and BDB tables.

## D.4.23. Changes in release 3.23.37 (17 Apr 2001)

- Fixed a bug when using `MATCH( )` in `HAVING` clause.
- Fixed a bug when using `HEAP` tables with `LIKE`.
- Added `--mysql-version` option to `safe_mysqld`
- Changed `INNOBASE` to `InnoDB` (because the `INNOBASE` name was in use). All **configure** options and **mysqld** start options now use `innodb` instead of `innobase`. This means that before upgrading to this version, you have to change any configuration files where you have used `innobase` options!
- Fixed bug when using indexes on `CHAR( 255 ) NULL` columns.
- Slave threads now start even if `master-host` is not set, as long as `server-id` is set and valid `master.info` is present.
- Partial updates (terminated with `kill`) are now logged with a special error code to the binary log. Slave refuses to execute them if the error code indicates the update was terminated abnormally, and has to be recovered with `SET SQL_SLAVE_SKIP_COUNTER=1; SLAVE START` after a manual sanity check/correction of data integrity.
- Fixed bug that erroneously logged a drop of internal temporary table on thread termination to the binary log --- this bug affected replication.
- Fixed a bug in `REGEXP` on 64-bit machines.
- `UPDATE` and `DELETE` with `WHERE unique_key_part IS NULL` didn't update/delete all rows.
- Disabled `INSERT DELAYED` for tables that support transactions.
- Fixed bug when using date functions on `TEXT/BLOB` column with wrong date format.
- UDFs now also work on Windows. (Patch by Ralph Mason.)
- Fixed bug in `ALTER TABLE` and `LOAD DATA INFILE` that disabled key-sorting. These commands should now be faster in most cases.
- Fixed performance bug where reopened tables (tables that had been waiting for `FLUSH` or `REPAIR TABLE`) would not use indexes for the next query.
- Fixed problem with `ALTER TABLE` to `InnoDB` tables on `FreeBSD`.
- Added **mysqld** variables `myisam_max_sort_file_size` and `myisam_max_extra_sort_file_size`.
- Initialize signals early to avoid problem with signals in `InnoDB`.
- Applied patch for the `tis620` character set to make comparisons case-independent and to fix a bug in `LIKE` for this character set. **Note:** All tables that use the `tis620` character set must be fixed with `myisamchk -r` or `REPAIR TABLE!`
- Added `--skip-safemalloc` option to **mysqld**.

## D.4.24. Changes in release 3.23.36 (27 Mar 2001)

- Fixed a bug that allowed use of database names containing a '.' character. This fixes a serious security issue when **mysqld** is run as root. (CVE-2001-0407 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2001-0407>])
- Fixed bug when thread creation failed (could happen when doing a **lot** of connections in a short time).
- Fixed some problems with `FLUSH TABLES` and `TEMPORARY` tables. (Problem with freeing the key cache and error `Can't reopen table...`)
- Fixed a problem in InnoDB with other character sets than `latin1` and another problem when using many columns.
- Fixed bug that caused a core dump when using a very complex query involving `DISTINCT` and summary functions.
- Added `SET TRANSACTION ISOLATION LEVEL ...`
- Added `SELECT ... FOR UPDATE`.
- Fixed bug where the number of affected rows was not returned when MySQL was compiled without transaction support.
- Fixed a bug in `UPDATE` where keys weren't always used to find the rows to be updated.
- Fixed a bug in `CONCAT_WS( )` where it returned incorrect results.
- Changed `CREATE ... SELECT` and `INSERT ... SELECT` to not allow concurrent inserts as this could make the binary log hard to repeat. (Concurrent inserts are enabled if you are not using the binary or update log.)
- Changed some macros to be able to use fast mutex with `glibc 2.2`.

### D.4.25. Changes in release 3.23.35 (15 Mar 2001)

- Fixed newly introduced bug in `ORDER BY`.
- Fixed wrong define `CLIENT_TRANSACTIONS`.
- Fixed bug in `SHOW VARIABLES` when using `INNOBASE` tables.
- Setting and using user variables in `SELECT DISTINCT` didn't work.
- Tuned `SHOW ANALYZE` for small tables.
- Fixed handling of arguments in the benchmark script `run-all-tests`.

### D.4.26. Changes in release 3.23.34a (11 Mar 2001)

- Added extra files to the distribution to allow `INNOBASE` support to be compiled.

### D.4.27. Changes in release 3.23.34 (10 Mar 2001)

- Added the `INNOBASE` storage engine and the `BDB` storage engine to the MySQL source distribution.

- Updated the documentation about GEMINI tables.
- Fixed a bug in `INSERT DELAYED` that caused threads to hang when inserting `NULL` into an `AUTO_INCREMENT` column.
- Fixed a bug in `CHECK TABLE / REPAIR TABLE` that could cause a thread to hang.
- Fixed problem that `REPLACE` would not replace a row that conflicts with an `AUTO_INCREMENT` generated key.
- **mysqld** now only sets `CLIENT_TRANSACTIONS` in `mysql->server_capabilities` if the server supports a transaction-safe storage engine.
- Fixed `LOAD DATA INFILE` to allow numeric values to be read into `ENUM` and `SET` columns.
- Improved error diagnostic for slave thread exit.
- Fixed bug in `ALTER TABLE ... ORDER BY`.
- Added `max_user_connections` variable to **mysqld**.
- Limit query length for replication by `max_allowed_packet`, not the arbitrary limit of 4MB.
- Allow space around `=` in argument to `--set-variable`.
- Fixed problem in automatic repair that could leave some threads in state `Waiting for table`.
- `SHOW CREATE TABLE` now displays the `UNION= ( )` for `MERGE` tables.
- `ALTER TABLE` now remembers the old `UNION= ( )` definition.
- Fixed bug when replicating timestamps.
- Fixed bug in bidirectional replication.
- Fixed bug in the `BDB` storage engine that occurred when using an index on multiple-part key where a key part may be `NULL`.
- Fixed `MAX ( )` optimization on sub-key for `BDB` tables.
- Fixed problem where garbage results were returned when using `BDB` tables and `BLOB` or `TEXT` fields when joining many tables.
- Fixed a problem with `BDB` tables and `TEXT` columns.
- Fixed bug when using a `BLOB` key where a const row wasn't found.
- Fixed that **mysqlbinlog** writes the timestamp value for each query. This ensures that one gets same values for date functions like `NOW ( )` when using **mysqlbinlog** to pipe the queries to another server.
- Allow `--skip-gemini`, `--skip-bdb`, and `--skip-innodb` options to be specified when invoking **mysqld**, even if these storage engines are not compiled in to **mysqld**.
- You can now use `ASC` and `DESC` with `GROUP BY` columns to specify a sort order.
- Fixed a deadlock in the `SET` code, when one ran `SET @foo=bar`, where `bar` is a column reference, an error was not properly generated.

## D.4.28. Changes in release 3.23.33 (09 Feb 2001)

- Fixed DNS lookups not to use the same mutex as the hostname cache. This enables known hosts to be quickly resolved even if a DNS lookup takes a long time.
- Added `--character-sets-dir` option to **mysampack**.
- Removed warnings when running `REPAIR TABLE ... EXTENDED`.
- Fixed a bug that caused a core dump when using `GROUP BY` on an alias, where the alias was the same as an existing column name.
- Added `SEQUENCE()` as an example user-defined function.
- Changed **mysql\_install\_db** to use `BINARY` for `CHAR` columns in the privilege tables.
- Changed `TRUNCATE tbl_name` to `TRUNCATE TABLE tbl_name` to use the same syntax as Oracle. Until 4.0 we also allow `TRUNCATE tbl_name` to not crash old code.
- Fixed "no found rows" bug in MyISAM tables when a BLOB was first part of a multiple-part key.
- Fixed bug where `CASE` didn't work with `GROUP BY`.
- Added `--sort-recover` option to **myisamchk**.
- **myisamchk -S** and `OPTIMIZE TABLE` now work on Windows.
- Fixed bug when using `DISTINCT` on results from functions that referred to a group function, like:  

```
SELECT a, DISTINCT SEC_TO_TIME(SUM(a))
FROM tbl_name GROUP BY a, b;
```
- Fixed buffer overrun in `libmysqlclient` library. Fixed bug in handling `STOP` event after `ROTATE` event in replication.
- Fixed another buffer overrun in `DROP DATABASE`.
- Added `Table_locks_immediate` and `Table_locks_waited` status variables.
- Fixed bug in replication that broke slave server start with existing `master.info`. This fixes a bug introduced in 3.23.32.
- Added `SET SQL_SLAVE_SKIP_COUNTER=n` command to recover from replication glitches without a full database copy.
- Added `max_binlog_size` variable; the binary log is rotated automatically when the size crosses the limit.
- Added `Last_Error`, `Last_Errno`, and `Slave_skip_counter` variables to `SHOW SLAVE STATUS`.
- Fixed bug in `MASTER_POS_WAIT()` function.
- Execute core dump handler on `SIGILL`, and `SIGBUS` in addition to `SIGSEGV`.
- On x86 Linux, print the current query and thread (connection) id, if available, in the core dump handler.
- Fixed several timing bugs in the test suite.
- Extended **mysqltest** to take care of the timing issues in the test suite.
- `ALTER TABLE` can now be used to change the definition for a `MERGE` table.

- Fixed creation of MERGE tables on Windows.
- Portability fixes for OpenBSD and OS/2.
- Added `--temp-pool` option to **mysqld**. Using this option causes most temporary files created to use a small set of names, rather than a unique name for each new file. This is to work around a problem in the Linux kernel dealing with creating a bunch of new files with different names. With the old behavior, Linux seems to "leak" memory, as it's being allocated to the directory entry cache instead of the disk cache.

## D.4.29. Changes in release 3.23.32 (22 Jan 2001)

- Changed code to get around compiler bug in Compaq C++ on OSF/1, that broke `BACKUP TABLE`, `RESTORE TABLE`, `CHECK TABLE`, `REPAIR TABLE`, and `ANALYZE TABLE`.
- Added option `FULL` to `SHOW COLUMNS`. Now we show the privilege list for the columns only if this option is given.
- Fixed bug in `SHOW LOGS` when there weren't any BDB logs.
- Fixed a timing problem in replication that could delay sending an update to the client until a new update was done.
- Don't convert field names when using `mysql_list_fields()`. This is to keep this code compatible with `SHOW FIELDS`.
- MERGE tables didn't work on Windows.
- Fixed problem with `SET PASSWORD=...` on Windows.
- Added missing `my_config.h` to RPM distribution.
- `TRIM("foo" from "foo")` didn't return an empty string.
- Added `--with-version-suffix` option to **configure**.
- Fixed core dump when client aborted connection without `mysql_close()`.
- Fixed a bug in `RESTORE TABLE` when trying to restore from a non-existent directory.
- Fixed a bug which caused a core dump on the slave when replicating `SET PASSWORD`.
- Added `MASTER_POS_WAIT()` function.

## D.4.30. Changes in release 3.23.31 (17 Jan 2001: Production)

- The test suite now tests all reachable BDB interface code. During testing we found and fixed many errors in the interface code.
- Using `HAVING` on an empty table could produce one result row when it shouldn't.
- Fixed the MySQL RPM so it no longer depends on Perl5.
- Fixed some problems with `HEAP` tables on Windows.
- `SHOW TABLE STATUS` didn't show correct average row length for tables larger than 4GB.

- CHECK TABLE ... EXTENDED didn't check row links for fixed size tables.
- Added option MEDIUM to CHECK TABLE.
- Fixed problem when using DECIMAL( ) keys on negative numbers.
- HOUR( ) (and some other TIME functions) on a CHAR column always returned NULL.
- Fixed security bug in SHOW GRANT (please upgrade if you are using an earlier MySQL 3.23 version). (CAN-2001-1275 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2001-1275>])
- Fixed buffer overflow bug when writing a certain error message. (CAN-2001-1274 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CAN-2001-1274>])
- Added usage of setrlimit( ) on Linux to get -O --open\_files\_limit=# to work on Linux.
- Added bdb\_version variable to **mysqld**.
- Fixed bug when using expression of type:  

```
SELECT ... FROM t1 LEFT JOIN t2 ON (t1.a=t2.a) WHERE t1.a=t2.a
```

In this case the test in the WHERE clause was wrongly optimized away.
- Fixed bug in MyISAM when deleting keys with possible NULL values, but the first key-column was not a prefix-compressed text column.
- Fixed **mysql.server** to read the [mysql.server] option file group rather than the [mysql\_server] group.
- Fixed **safe\_mysqld** and **mysql.server** to also read the server option section.
- Added Threads\_created status variable to **mysqld**.

## D.4.31. Changes in release 3.23.30 (04 Jan 2001)

- Added SHOW OPEN TABLES command.
- Fixed that myisamdump works against old **mysqld** servers.
- Fixed **myisamchk -k#** so that it works again.
- Fixed a problem with replication when the binary log file went over 2G on 32-bit systems.
- LOCK TABLES now automatically starts a new transaction.
- Changed BDB tables to not use internal subtransactions and reuse open files to get more speed.
- Added --mysqld=# option to **safe\_mysqld**.
- Allow hex constants in the --fields-\*-by and --lines-terminated-by options to **mysqldump** and **mysqlimport**. By Paul DuBois.
- Added --safe-show-database option to **mysqld**.
- Added have\_bdb, have\_gemini, have\_innobase, have\_raid and have\_openssl to SHOW VARIABLES to make it easy to test for supported extensions.
- Added --open-files-limit option to **mysqld**.
- Changed --open-files option to --open-files-limit in **safe\_mysqld**.

- Fixed a bug where some rows were not found with HEAP tables that had many keys.
- Fixed that `--bdb-no-sync` works.
- Changed `--bdb-recover` to `--bdb-no-recover` as recover should be on by default.
- Changed the default number of BDB locks to 10000.
- Fixed a bug from 3.23.29 when allocating the shared structure needed for BDB tables.
- Changed `mysqld_multi.sh` to use configure variables. Patch by Christopher McCrory.
- Added fixing of include files for Solaris 2.8.
- Fixed bug with `--skip-networking` on Debian Linux.
- Fixed problem that some temporary files were reported as having the name UNOPENED in error messages.
- Fixed bug when running two simultaneous `SHOW LOGS` queries.

## D.4.32. Changes in release 3.23.29 (16 Dec 2000)

- Configure updates for Tru64, large file support, and better TCP wrapper support. By Albert Chin-A-Young.
- Fixed bug in `<=>` operator.
- Fixed bug in `REPLACE` with BDB tables.
- `LPAD( )` and `RPAD( )` shortens the result string if it's longer than the length argument.
- Added `SHOW LOGS` command.
- Remove unused BDB logs on shutdown.
- When creating a table, put `PRIMARY` keys first, followed by `UNIQUE` keys.
- Fixed a bug in `UPDATE` involving multiple-part keys where you specified all key parts both in the update and the `WHERE` part. In this case MySQL could try to update a record that didn't match the whole `WHERE` part.
- Changed drop table to first drop the tables and then the `.frm` file.
- Fixed a bug in the hostname cache which caused `mysqld` to report the hostname as `' '` in some error messages.
- Fixed a bug with HEAP type tables; the variable `max_heap_table_size` wasn't used. Now either `MAX_ROWS` or `max_heap_table_size` can be used to limit the size of a HEAP type table.
- Changed the default `server-id` value to 1 for masters and 2 for slaves to make it easier to use the binary log.
- Renamed `bdb_lock_max` variable to `bdb_max_lock`.
- Added support for `AUTO_INCREMENT` on sub-fields for BDB tables.
- Added `ANALYZE TABLE` of BDB tables.
- In BDB tables, we now store the number of rows; this helps to optimize queries when we need an approximation of the number of rows.

- If we get an error in a multiple-row statement, we now only roll back the last statement, not the entire transaction.
- If you do a ROLLBACK when you have updated a non-transactional table you get an error as a warning.
- Added `--bdb-shared-data` option to **mysqld**.
- Added `Slave_open_temp_tables` status variable to **mysqld**
- Added `binlog_cache_size` and `max_binlog_cache_size` variables to **mysqld**.
- `DROP TABLE`, `RENAME TABLE`, `CREATE INDEX` and `DROP INDEX` are now transaction endpoints.
- If you do a `DROP DATABASE` on a symbolically linked database, both the link and the original database are deleted.
- Fixed `DROP DATABASE` to work on OS/2.
- Fixed bug when doing a `SELECT DISTINCT ... table1 LEFT JOIN table2 ...` when `table2` was empty.
- Added `--abort-slave-event-count` and `--disconnect-slave-event-count` options to **mysqld** for debugging and testing of replication.
- Fixed replication of temporary tables. Handles everything except slave server restart.
- `SHOW KEYS` now shows whether key is `FULLTEXT`.
- New script **mysqld\_multi**. See Section 5.1.5, “The **mysqld\_multi** Program for Managing Multiple MySQL Servers”.
- Added new script, `mysql-multi.server.sh`. Thanks to Tim Bunce <Tim.Bunce@ig.co.uk> for modifying **mysql.server** to easily handle hosts running many **mysqld** processes.
- **safe\_mysqld**, **mysql.server**, and **mysql\_install\_db** have been modified to use `mysql_print_defaults` instead of various hacks to read the `my.cnf` files. In addition, the handling of various paths has been made more consistent with how **mysqld** handles them by default.
- Automatically remove Berkeley DB transaction logs that no longer are in use.
- Fixed bug with several `FULLTEXT` indexes in one table.
- Added a warning if number of rows changes on `REPAIR TABLE/OPTIMIZE TABLE`.
- Applied patches for OS/2 by Yuri Dario.
- `FLUSH TABLES tbl_name` didn't always flush the index tree to disk properly.
- `--bootstrap` is now run in a separate thread. This fixes a problem that caused **mysql\_install\_db** to core dump on some Linux machines.
- Changed `mi_create()` to use less stack space.
- Fixed bug with optimizer trying to over-optimize `MATCH()` when used with `UNIQUE` key.
- Changed `crash-me` and the MySQL benchmarks to also work with FrontBase.
- Allow `RESTRICT` and `CASCADE` after `DROP TABLE` to make porting easier.
- Reset status variable which could cause problem if one used `--slow-log`.

- Added `connect_timeout` variable to **mysql** and **mysqladmin**.
- Added `connect-timeout` as an alias for `timeout` for option files read by `mysql_options()`.

### D.4.33. Changes in release 3.23.28 (22 Nov 2000: Gamma)

- Added new options `--pager[=...]`, `--no-pager`, `--tee=...` and `--no-tee` to the **mysql** client. The new corresponding interactive commands are `pager`, `nopager`, `tee` and `notee`. See Section 8.3, “**mysql**, the Command-Line Tool”, **mysql --help** and the interactive help for more information.
- Fixed crash when automatic repair of MyISAM table failed.
- Fixed a major performance bug in the table locking code when a lot of `SELECT`, `UPDATE` and `INSERT` statements constantly were running. The symptom was that the `UPDATE` and `INSERT` queries were locked for a long time while new `SELECT` statements were executed before the updates.
- When reading `options_files` with `mysql_options()` the `return-found-rows` option was ignored.
- You can now specify `interactive-timeout` in the option file that is read by `mysql_options()`. This makes it possible to force programs that run for a long time (like **mysqlhotcopy**) to use the `interactive_timeout` time instead of the `wait_timeout` time.
- Added to the slow query log the time and the username for each logged query. If you are using `--log-long-format` then also queries that do not use an index are logged, even if the query takes less than `long_query_time` seconds.
- Fixed a problem in `LEFT JOIN` which caused all columns in a reference table to be `NULL`.
- Fixed a problem when using `NATURAL JOIN` without keys.
- Fixed a bug when using a multiple-part keys where the first part was of type `TEXT` or `BLOB`.
- `DROP` of temporary tables wasn't stored in the update/binary log.
- Fixed a bug where `SELECT DISTINCT * ... LIMIT row_count` only returned one row.
- Fixed a bug in the assembler code in `strstr()` for `SPARC` and cleaned up the `global.h` header file to avoid a problem with bad aliasing with the compiler submitted with Red Hat 7.0. (Reported by Trond Eivind Glomsrød)
- The `--skip-networking` option now works properly on NT.
- Fixed a long outstanding bug in the `ISAM` tables when a row with a length of more than 65KB was shortened by a single byte.
- Fixed a bug in MyISAM when running multiple updating processes on the same table.
- Allow one to use `FLUSH TABLE tbl_name`.
- Added `--replicate-ignore-table`, `--replicate-do-table`, `--replicate-wild-ignore-table`, and `--replicate-wild-do-table` options to **mysqld**.

- Changed all log files to use our own `IO_CACHE` mechanism instead of `FILE` to avoid OS problems when there are many files open.
- Added `--open-files` and `--timezone` options to **safe\_mysqld**.
- Fixed a fatal bug in `CREATE TEMPORARY TABLE ... SELECT ...`.
- Fixed a problem with `CREATE TABLE ... SELECT NULL`.
- Added variables `large_file_support`, `net_read_timeout`, `net_write_timeout` and `query_buffer_size` to `SHOW VARIABLES`.
- Added status variables `Created_tmp_files` and `Sort_merge_passes` to `SHOW STATUS`.
- Fixed a bug where we didn't allow an index name after the `FOREIGN KEY` definition.
- Added `TRUNCATE tbl_name` as a synonym for `DELETE FROM tbl_name`.
- Fixed a bug in a BDB key compare function when comparing part keys.
- Added `bdb_lock_max` variable to **mysqld**.
- Added more tests to the benchmark suite.
- Fixed an overflow bug in the client code when using overly long database names.
- `mysql_connect()` now aborts on Linux if the server doesn't answer in `timeout` seconds.
- `SLAVE START` did not work if you started with `--skip-slave-start` and had not explicitly run `CHANGE MASTER TO`.
- Fixed the output of `SHOW MASTER STATUS` to be consistent with `SHOW SLAVE STATUS`. (It now has no directory in the log name.)
- Added `PURGE MASTER LOGS TO`.
- Added `SHOW MASTER LOGS` statement to display a list of binary log files.
- Added `--safemalloc-mem-limit` option to **mysqld** to simulate memory shortage when compiled with the `--with-debug=full` option.
- Fixed several core dumps in out-of-memory conditions.
- `SHOW SLAVE STATUS` was using an uninitialized mutex if the slave had not been started yet.
- Fixed bug in `ELT()` and `MAKE_SET()` when the query used a temporary table.
- `CHANGE MASTER TO` without specifying `MASTER_LOG_POS` would set it to 0 instead of 4 and hit the magic number in the master binary log.
- `ALTER TABLE ... ORDER BY ...` syntax added. This creates the new table with the rows in a specific order.

## D.4.34. Changes in release 3.23.27 (24 Oct 2000)

- Fixed a bug where the automatic repair of MyISAM tables sometimes failed when the data file was corrupt.
- Fixed a bug in `SHOW CREATE` when using `AUTO_INCREMENT` columns.
- Changed BDB tables to use new compare function in Berkeley DB 3.2.3.

- You can now use Unix socket files with MIT-pthreads.
- Added the `latin5` (turkish) character set.
- Small portability fixes.

## D.4.35. Changes in release 3.23.26 (18 Oct 2000)

- Renamed `FLUSH MASTER` and `FLUSH SLAVE` to `RESET MASTER` and `RESET SLAVE`.
- Fixed `<>` to work properly with `NULL`.
- Fixed a problem with `SUBSTRING_INDEX()` and `REPLACE()`. (Patch by Alexander Igonitchev)
- Fix `CREATE TEMPORARY TABLE IF NOT EXISTS` not to produce an error if the table exists.
- If you don't create a `PRIMARY KEY` in a BDB table, a hidden `PRIMARY KEY` is created.
- Added read-only-key optimization to BDB tables.
- `LEFT JOIN` in some cases preferred a full table scan when there was no `WHERE` clause.
- When using `--log-slow-queries`, don't count the time waiting for a lock.
- Fixed bug in lock code on Windows which could cause the key cache to report that the key file was crashed even if it was okay.
- Automatic repair of MyISAM tables if you start **mysqld** with `--myisam-recover`.
- Removed the `TYPE=` keyword from `CHECK TABLE` and `REPAIR TABLE`. Allow `CHECK TABLE` options to be combined. (You can still use `TYPE=`, but this usage is deprecated.)
- Fixed mutex bug in the binary replication log --- long update queries could be read only in part by the slave if it did it at the wrong time, which was not fatal, but resulted in a performance-degrading reconnect and a scary message in the error log.
- Changed the format of the binary log --- added magic number, server version, binary log version. Added the server ID and query error code for each query event.
- Replication thread from the slave now kills all the stale threads from the same server.
- Long replication usernames were not being handled properly.
- Added `--replicate-rewrite-db` option to **mysqld**.
- Added `--skip-slave-start` option to **mysqld**.
- Updates that generated an error code (such as `INSERT INTO foo(some_key) values (1), (1)`) erroneously terminated the slave thread.
- Added optimization of queries where `DISTINCT` is used only on columns from some of the tables.
- Allow floating-point numbers where there is no sign after the exponent (like `1e1`).
- `SHOW GRANTS` didn't always show all column grants.
- Added `--default-extra-file=#` option to all MySQL clients.
- Columns referenced in `INSERT` statements now are initialized properly.

- UPDATE didn't always work when used with a range on a timestamp that was part of the key that was used to find rows.
- Fixed a bug in FULLTEXT index when inserting a NULL column.
- Changed to use `mkstemp()` instead of `tempnam()`. Based on a patch from John Jones.

## D.4.36. Changes in release 3.23.25 (29 Sep 2000)

- Fixed that `databasename` works as second argument to `mysqlhotcopy`.
- The values for the `UMASK` and `UMASK_DIR` environment variables now can be specified in octal by beginning the value with a zero.
- Added `RIGHT JOIN`. This makes `RIGHT` a reserved word.
- Added `@@IDENTITY` as a synonym for `LAST_INSERT_ID()`. (This is for MSSQL compatibility.)
- Fixed a bug in `myisamchk` and `REPAIR TABLE` when using FULLTEXT index.
- `LOAD DATA INFILE` now works with FIFOs. (Patch by Toni L. Harbaugh-Blackford.)
- `FLUSH LOGS` broke replication if you specified a log name with an explicit extension as the value of the `log-bin` option.
- Fixed a bug in MyISAM with packed multiple-part keys.
- Fixed crash when using `CHECK TABLE` on Windows.
- Fixed a bug where FULLTEXT index always used the `koi8_ukr` character set.
- Fixed privilege checking for `CHECK TABLE`.
- The MyISAM repair/reindex code didn't use the `--tmpdir` option for its temporary files.
- Added `BACKUP TABLE` and `RESTORE TABLE`.
- Fixed core dump on `CHANGE MASTER TO` when the slave did not have the master to start with.
- Fixed incorrect Time in the processlist for `Connect` of the slave thread.
- The slave now logs when it connects to the master.
- Fixed a core dump bug when doing `FLUSH MASTER` if you didn't specify a filename argument to `--log-bin`.
- Added missing `ha_berkeley.x` files to the MySQL Windows distribution.
- Fixed some mutex bugs in the log code that could cause thread blocks if new log files couldn't be created.
- Added lock time and number of selected processed rows to slow query log.
- Added `--memlock` option to `mysqld` to lock `mysqld` in memory on systems with the `mlock-all()` call (as in Solaris).
- HEAP tables didn't use keys properly. (Bug from 3.23.23.)
- Added better support for MERGE tables (keys, mapping, creation, documentation...). See Section 14.2, "The MERGE Storage Engine".

- Fixed bug in **mysqldump** from 3.23 which caused some CHAR columns not to be quoted.
- Merged `analyze`, `check`, `optimize` and `repair` code.
- `OPTIMIZE TABLE` is now mapped to `REPAIR TABLE` with statistics and sorting of the index tree. This means that for the moment it only works on MyISAM tables.
- Added a pre-allocated block to `root_malloc` to get fewer mallocs.
- Added a lot of new statistics variables.
- Fixed `ORDER BY` bug with BDB tables.
- Removed warning that **mysqld** couldn't remove the `.pid` file under Windows.
- Changed `--log-isam` to log MyISAM tables instead of isam tables.
- Fixed `CHECK TABLE` to work on Windows.
- Added file mutexes to make `pwrite()` safe on Windows.

### D.4.37. Changes in release 3.23.24 (08 Sep 2000)

- Added `Created_tmp_disk_tables` variable to **mysqld**.
- To make it possible to reliably dump and restore tables with `TIMESTAMP(X)` columns, MySQL now reports columns with `X` other than 14 or 8 to be strings.
- Changed sort order for `latin1` as it was before MySQL 3.23.23. Any table that was created or modified with 3.23.22 must be repaired if it has CHAR columns that may contain characters with ASCII values greater than 128!
- Fixed small memory leak introduced from 3.23.22 when creating a temporary table.
- Fixed problem with BDB tables and reading on a unique (not primary) key.
- Restored the `win1251` character set (it's now only marked deprecated).

### D.4.38. Changes in release 3.23.23 (01 Sep 2000)

- Changed sort order for 'German'; all tables created with 'German' sortorder must be repaired with `REPAIR TABLE` or **myisamchk** before use!
- Added `--core-file` option to **mysqld** to get a core file on Linux if **mysqld** dies on the SIGSEGV signal.
- MySQL client **mysql** now starts with option `--no-named-commands` (`-g`) by default. This option can be disabled with `--enable-named-commands` (`-G`). This may cause incompatibility problems in some cases, for example, in SQL scripts that use named commands without a semicolon, etc.! Long format commands still work from the first line.
- Fixed a problem when using many pending `DROP TABLE` statements at the same time.
- Optimizer didn't use keys properly when using `LEFT JOIN` on an empty table.
- Added shorter help text when invoking **mysqld** with incorrect options.
- Fixed non-fatal `free()` bug in **mysqlimport**.

- Fixed bug in MyISAM index handling of DECIMAL/NUMERIC keys.
- Fixed a bug in concurrent insert in MyISAM tables. In some contexts, usage of `MIN(key_part)` or `MAX(key_part)` returned an empty set.
- Updated **mysqldhotcopy** to use the new `FLUSH TABLES table_list` syntax. Only tables which are being backed up are flushed now.
- Changed behavior of `--enable-thread-safe-client` so that both non-threaded (`-lmysqlclient`) and threaded (`-lmysqlclient_r`) libraries are built. Users who linked against a threaded `-lmysqlclient` need to link against `-lmysqlclient_r` now.
- Added atomic `RENAME TABLE` command.
- Don't count NULL values in `COUNT(DISTINCT ...)`.
- Changed `ALTER TABLE`, `LOAD DATA INFILE` on empty tables and `INSERT ... SELECT ...` on empty tables to create non-unique indexes in a separate batch with sorting. This makes these statements much faster when you have many indexes.
- `ALTER TABLE` now logs the first used `insert_id` correctly.
- Fixed crash when adding a default value to a BLOB column.
- Fixed a bug with `DATE_ADD/DATE_SUB` where it returned a datetime instead of a date.
- Fixed a problem with the thread cache which made some threads show up as `***DEAD***` in `SHOW PROCESSLIST`.
- Fixed a lock in our `thr_rwlock` code, which could make selects that run at the same time as concurrent inserts crash. This affects only systems that don't have the `pthread_rwlock_rdlock` code.
- When deleting rows with a non-unique key in a HEAP table, all rows weren't always deleted.
- Fixed bug in range optimizer for HEAP tables for searches on a part index.
- Fixed `SELECT` on part keys to work with BDB tables.
- Fixed `INSERT INTO bdb_table ... SELECT` to work with BDB tables.
- `CHECK TABLE` now updates key statistics for the table.
- `ANALYZE TABLE` now only updates tables that have been changed since the last `ANALYZE TABLE`. Note that this is a new feature and tables are not marked to be analyzed until they are updated in any way with 3.23.23 or newer. For older tables, you have to do `CHECK TABLE` to update the key distribution.
- Fixed some minor privilege problems with `CHECK TABLE`, `ANALYZE TABLE`, `REPAIR TABLE` and `SHOW CREATE` commands.
- Added `CHANGE MASTER TO` statement.
- Added `FAST`, `QUICK` `EXTENDED` check types to `CHECK TABLES`.
- Changed **mysamchk** so that `--fast` and `--check-only-changed` are also honored with `--sort-index` and `--analyze`.
- Fixed fatal bug in `LOAD TABLE FROM MASTER` that did not lock the table during index rebuild.
- `LOAD DATA INFILE` broke replication if the database was excluded from replication.
- More variables in `SHOW SLAVE STATUS` and `SHOW MASTER STATUS`.

- `SLAVE STOP` now does not return until the slave thread actually exits.
- Full-text search via the `MATCH ( )` function and `FULLTEXT` index type (for MyISAM files). This makes `FULLTEXT` a reserved word.

### D.4.39. Changes in release 3.23.22 (31 Jul 2000)

- Fixed that `lex_hash.h` is created properly for each MySQL distribution.
- Fixed that `MASTER` and `COLLECTION` are not reserved words.
- The log generated by `--slow-query-log` didn't contain the whole queries.
- Fixed that open transactions in BDB tables are rolled back if the connection is closed unexpectedly.
- Added workaround for a bug in `gcc 2.96 (intel)` and `gcc 2.9 (IA-64)` in `gen_lex_hash.c`.
- Fixed memory leak in the client library when using `host=` in the `my.cnf` file.
- Optimized functions that manipulate the hours/minutes/seconds.
- Fixed bug when comparing the result of `DATE_ADD ( )/DATE_SUB ( )` against a number.
- Changed the meaning of `-F`, `--fast` for `myisamchk`. Added `-C`, `--check-only-changed` option to `myisamchk`.
- Added `ANALYZE tbl_name` to update key statistics for tables.
- Changed binary items `0x. . .` to be regarded as integers by default.
- Fix for `SCO` and `SHOW PROCESSLIST`.
- Added `auto-rehash` on reconnect for the `mysql` client.
- Fixed a newly introduced bug in MyISAM, where the index file couldn't get bigger than 64MB.
- Added `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`.

### D.4.40. Changes in release 3.23.21 (04 Jul 2000)

- Added `mysql_character_set_name ( )` function to the MySQL C API.
- Made the update log ASCII 0 safe.
- Added the `mysql_config` script.
- Fixed problem when using `<` or `>` with a char column that was only partly indexed.
- One would get a core dump if the log file was not readable by the MySQL user.
- Changed `mysqladmin` to use `CREATE DATABASE` and `DROP DATABASE` statements instead of the old deprecated API calls.
- Fixed chown warning in `safe_mysqld`.
- Fixed a bug in `ORDER BY` that was introduced in 3.23.19.
- Only optimize the `DELETE FROM tbl_name` to do a drop+create of the table if we are in

AUTOCOMMIT mode (needed for BDB tables).

- Added extra checks to avoid index corruption when the ISAM/MyISAM index files get full during an INSERT/UPDATE.
- **myisamchk** didn't correctly update row checksum when used with `-ro` (this only gave a warning in subsequent runs).
- Fixed bug in `REPAIR TABLE` so that it works with tables without indexes.
- Fixed buffer overrun in `DROP DATABASE`.
- `LOAD TABLE FROM MASTER` is sufficiently bug-free to announce it as a feature.
- `MATCH` and `AGAINST` are now reserved words.

## D.4.41. Changes in release 3.23.20 (28 Jun 2000: Beta)

- Fixed bug in 3.23.19; `DELETE FROM tbl_name` removed the `.frm` file.
- Added `SHOW CREATE TABLE`.

## D.4.42. Changes in release 3.23.19

- Changed copyright for all files to GPL for the server code and utilities and to LGPL for the client libraries. See <http://www.fsf.org/licenses/>.
- Fixed bug where all rows matching weren't updated on a MyISAM table when doing update based on key on a table with many keys and some key changed values.
- The Linux MySQL RPMs and binaries are now statically linked with a linuxthread version that has faster mutex handling when used with MySQL.
- `ORDER BY` can now use REF keys to find subsets of the rows that need to be sorted.
- Changed name of **print\_defaults** program to **my\_print\_defaults** to avoid name confusion.
- Fixed `NULLIF ( )` to work as required by standard SQL.
- Added `net_read_timeout` and `net_write_timeout` as startup parameters to **mysqld**.
- Fixed bug that destroyed index when doing **myisamchk --sort-records** on a table with prefix compressed index.
- Added **pack\_isam** and **myisampack** to the standard MySQL distribution.
- Added the syntax `BEGIN WORK` (the same as `BEGIN`).
- Fixed core dump bug when using `ORDER BY` on a `CONV ( )` expression.
- Added `LOAD TABLE FROM MASTER`.
- Added `FLUSH MASTER` and `FLUSH SLAVE`.
- Fixed big/little endian problem in the replication.

## D.4.43. Changes in release 3.23.18 (11 Jun 2000)

- Fixed a problem from 3.23.17 when choosing character set on the client side.
- Added `FLUSH TABLES WITH READ LOCK` to make a global lock suitable for making a copy of MySQL data files.
- `CREATE TABLE ... SELECT ... PROCEDURE` now works.
- Internal temporary tables now use compressed index when using `GROUP BY` on `VARCHAR/CHAR` columns.
- Fixed a problem when locking the same table with both a `READ` and a `WRITE` lock.
- Fixed problem with **myisamchk** and `RAID` tables.

## D.4.44. Changes in release 3.23.17 (07 Jun 2000)

- Fixed a bug in `FIND_IN_SET()` when the first argument was `NULL`.
- Added table locks to Berkeley DB.
- Fixed a bug with `LEFT JOIN` and `ORDER BY` where the first table had only one matching row.
- Added 4 sample `my.cnf` example files in the `support-files` directory.
- Fixed duplicated key problem when doing big `GROUP BY` operations. (This bug was probably introduced in 3.23.15.)
- Changed syntax for `INNER JOIN` to match standard SQL.
- Added `NATURAL JOIN` syntax.
- A lot of fixes in the BDB interface.
- Added handling of `--no-defaults` and `--defaults-file` to **safe\_mysqld.sh** and **mysql\_install\_db.sh**.
- Fixed bug in reading compressed tables with many threads.
- Fixed that `USE INDEX` works with `PRIMARY` keys.
- Added `BEGIN` statement to start a transaction in `AUTOCOMMIT` mode.
- Added support for symbolic links for Windows.
- Changed protocol to let client know if the server is in `AUTOCOMMIT` mode and if there is a pending transaction. If there is a pending transaction, the client library gives an error before re-connecting to the server to let the client know that the server did a rollback. The protocol is still backward-compatible with old clients.
- `KILL` now works on a thread that is locked on a 'write' to a dead client.
- Fixed memory leak in the replication slave thread.
- Added new `log-slave-updates` option to **mysqld**, to allow daisy-chaining the slaves.
- Fixed compile error on FreeBSD and other systems where `pthread_t` is not the same as `int`.
- Fixed master shutdown aborting the slave thread.
- Fixed a race condition in `INSERT DELAYED` code when doing `ALTER TABLE`.
- Added deadlock detection sanity checks to `INSERT DELAYED`.

## D.4.45. Changes in release 3.23.16 (16 May 2000)

- Added `SLAVE START` and `SLAVE STOP` statements.
- Added `TYPE=QUICK` option to `CHECK TABLE` and to `REPAIR TABLE`.
- Fixed bug in `REPAIR TABLE` when the table was in use by other threads.
- Added a thread cache to make it possible to debug MySQL with `gdb` when one does a lot of re-connects. This also improves systems where you can't use persistent connections.
- Lots of fixes in the Berkeley DB interface.
- `UPDATE IGNORE` does not abort if an update results in a `DUPLICATE_KEY` error.
- Put `CREATE TEMPORARY TABLE` commands in the update log.
- Fixed bug in handling of masked IP numbers in the privilege tables.
- Fixed bug with `delay_key_write` tables and `CHECK TABLE`.
- Added `--replicate-do-db` and `--replicate-ignore-db` options to `mysqld`, to restrict which databases get replicated.
- Added `SQL_LOG_BIN` option.

## D.4.46. Changes in release 3.23.15 (08 May 2000)

- To start `mysqld` as `root`, you must now use the `--user=root` option.
- Added interface to Berkeley DB. (This is not yet functional; play with it at your own risk!)
- Replication between master and slaves.
- Fixed bug that other threads could steal a lock when a thread had a lock on a table and did a `FLUSH TABLES` command.
- Added the `slow_launch_time` variable and the `Slow_launch_threads` status variable to `mysqld`. These can be examined with `mysqladmin variables` and `mysqladmin extended-status`.
- Added functions `INET_NTOA()` and `INET_ATON()`.
- The default type of `IF()` now depends on the second and third arguments and not only on the second argument.
- Fixed case when `myisamchk` could go into a loop when trying to repair a crashed table.
- Don't write `INSERT DELAYED` to update log if `SQL_LOG_UPDATE=0`.
- Fixed problem with `REPLACE` on `HEAP` tables.
- Added possible character sets and time zone to `SHOW VARIABLES` output.
- Fixed bug in locking code that could result in locking problems with concurrent inserts under high load.
- Fixed a problem with `DELETE` of many rows on a table with compressed keys where MySQL scanned the index to find the rows.
- Fixed problem with `CHECK TABLE` on table with deleted keyblocks.

- Fixed a bug in reconnect (at the client side) where it didn't free memory properly in some contexts.
- Fixed problems in update log when using `LAST_INSERT_ID()` to update a table with an `AUTO_INCREMENT` key.
- Added `NULLIF()` function.
- Fixed bug when using `LOAD DATA INFILE` on a table with `BLOB/TEXT` columns.
- Optimized `MyISAM` to be faster when inserting keys in sorted order.
- `EXPLAIN SELECT . . .` now also prints out whether MySQL needs to create a temporary table or use file sorting when resolving the `SELECT`.
- Added optimization to skip `ORDER BY` parts where the part is a constant expression in the `WHERE` part. Indexes can now be used even if the `ORDER BY` doesn't match the index exactly, as long as all the unused index parts and all the extra `ORDER BY` columns are constants in the `WHERE` clause. See Section 7.4.5, "How MySQL Uses Indexes".
- `UPDATE` and `DELETE` on a whole unique key in the `WHERE` part are now faster than before.
- Changed `RAID_CHUNKSIZE` to be in 1024-byte increments.
- Fixed core dump in `LOAD_FILE(NULL)`.

## D.4.47. Changes in release 3.23.14 (09 Apr 2000)

- Added `mysqlbinlog` program for displaying binary log files in text format.
- Added `mysql_real_escape_string()` function to the MySQL C API.
- Fixed a bug in `CONCAT()` where one of the arguments was a function that returned a modified argument.
- Fixed a critical bug in `myisamchk`, where it updated the header in the index file when one only checked the table. This confused the `mysqld` daemon if it updated the same table at the same time. Now the status in the index file is only updated if one uses `--update-state`. With older `myisamchk` versions you should use `--read-only` when only checking tables, if there is the slightest chance that the `mysqld` server is working on the table at the same time!
- Fixed that `DROP TABLE` is logged in the update log.
- Fixed problem when searching on `DECIMAL()` key field where the column data contained leading zeros.
- Fix bug in `myisamchk` when the `AUTO_INCREMENT` column isn't the first key.
- Allow `DATETIME` in ISO8601 format: 2000-03-12T12:00:00
- Dynamic character sets. A `mysqld` binary can now handle many different character sets (you can choose which when starting `mysqld`).
- Added `REPAIR TABLE` statement.
- Added `mysql_thread_safe()` function to the MySQL C API.
- Added the `UMASK_DIR` environment variable.
- Added `CONNECTION_ID()` function to return the client connection thread ID.
- When using `=` on `BLOB` or `VARCHAR BINARY` keys, where only a part of the column was in-

dexed, the whole column of the result row wasn't compared.

- Fix for `sjis` character set and `ORDER BY`.
- When running in ANSI mode, don't allow columns to be used that aren't in the `GROUP BY` part.

## D.4.48. Changes in release 3.23.13 (14 Mar 2000)

- Fixed problem when doing locks on the same table more than 2 times in the same `LOCK TABLE` command; this fixed the problem one got when running the test-ATIS test with `--fast` or `--check-only-changed`.
- Added `SQL_BUFFER_RESULT` option to `SELECT`.
- Removed endspace from double/float numbers in results from temporary tables.
- Added `CHECK TABLE` command.
- Added changes for MyISAM in 3.23.12 that didn't get into the source distribution because of CVS problems.
- Fixed bug so that **mysqladmin shutdown** waits for the local server to close down.
- Fixed a possible endless loop when calculating timestamp.
- Added **print\_defaults** program to the `.rpm` files. Removed **mysqlbug** from the client `.rpm` file.

## D.4.49. Changes in release 3.23.12 (07 Mar 2000)

- Fixed bug in MyISAM involving `REPLACE ... SELECT ...` which could give a corrupted table.
- Fixed bug in **myisamchk** where it incorrectly reset the `AUTO_INCREMENT` value.
- LOTS of patches for Linux Alpha. MySQL now appears to be relatively stable on Alpha.
- Changed `DISTINCT` on HEAP temporary tables to use hashed keys to quickly find duplicated rows. This mostly concerns queries of type `SELECT DISTINCT ... GROUP BY ...`. This fixes a problem where not all duplicates were removed in queries of the above type. In addition, the new code is MUCH faster.
- Added patches to make MySQL compile on Mac OS X.
- Added `IF NOT EXISTS` clause to `CREATE DATABASE`.
- Added `--all-databases` and `--databases` options to **mysqldump** to allow dumping of many databases at the same time.
- Fixed bug in compressed `DECIMAL()` index in MyISAM tables.
- Fixed bug when storing 0 into a timestamp.
- When doing **mysqladmin shutdown** on a local connection, **mysqladmin** now waits until the PID file is gone before terminating.
- Fixed core dump with some `COUNT(DISTINCT ...)` queries.
- Fixed that **myisamchk** works properly with RAID tables.

- Fixed problem with `LEFT JOIN` and `key_col IS NULL`.
- Fixed bug in `net_clear()` which could give the error `Aborted connection` in the MySQL clients.
- Added options `USE INDEX (key_list)` and `IGNORE INDEX (key_list)` as parameters in `SELECT`.
- `DELETE` and `RENAME` should now work on RAID tables.

## D.4.50. Changes in release 3.23.11 (16 Feb 2000)

- Added `HIGH_PRIORITY` option to `INSERT`. This overrides the effect of the `--low-priority-updates` server option and does not perform concurrent inserts.
- Allow the `ALTER TABLE tbl_name ADD (field_list)` syntax.
- Fixed problem with optimizer that could sometimes use incorrect keys.
- Fixed that `GRANT/REVOKE ALL PRIVILEGES` doesn't affect `GRANT OPTION`.
- Removed extra `'` from the output of `SHOW GRANTS`.
- Fixed problem when storing numbers in timestamps.
- Fix problem with time zones that have half hour offsets.
- Allow the syntax `UNIQUE INDEX` in `CREATE` statements.
- **mysqlhotcopy** - fast online hot-backup utility for local MySQL databases. By Tim Bunce.
- New more secure **mysqlaccess**. Thanks to Steve Harvey for this.
- Added `--i-am-a-dummy` and `--safe-updates` options to **mysql**.
- Added `select_limit` and `max_join_size` variables to **mysql**.
- Added `SQL_MAX_JOIN_SIZE` and `SQL_SAFE_UPDATES` options.
- Added `READ LOCAL` lock that doesn't lock the table for concurrent inserts. (This is used by **mysqldump**.)
- Changed that `LOCK TABLES ... READ` no longer allows concurrent inserts.
- Added `--skip-delay-key-write` option to **mysqld**.
- Fixed security problem in the protocol regarding password checking.
- `_rowid` can now be used as an alias for an integer type unique indexed column.
- Added back blocking of `SIGPIPE` when compiling with `--thread-safe-clients` to make things safe for old clients.

## D.4.51. Changes in release 3.23.10 (30 Jan 2000)

- Fixed bug in 3.23.9 where memory wasn't properly freed when using `LOCK TABLES`.

## D.4.52. Changes in release 3.23.9 (29 Jan 2000)

- Fixed problem that affected queries that did arithmetic on group functions.
- Fixed problem with timestamps and `INSERT DELAYED`.
- Fixed that `date_col BETWEEN const_date AND const_date` works.
- Fixed problem when only changing a 0 to NULL in a table with BLOB/TEXT columns.
- Fixed bug in range optimizer when using many key parts and or on the middle key parts: `WHERE K1=1 and K3=2 and (K2=2 and K4=4 or K2=3 and K4=5)`
- Added `source` command to **mysql** to allow reading of batch files inside the **mysql** client. Original patch by Matthew Vanecek.
- Fixed critical problem with the `WITH GRANT OPTION` option.
- Don't give an unnecessary GRANT error when using tables from many databases in the same query.
- Added VIO wrapper (needed for SSL support; by Andrei Errapart and Tõnu Samuel).
- Fixed optimizer problem on SELECT when using many overlapping indexes. MySQL should now be able to choose keys even better when there are many keys to choose from.
- Changed optimizer to prefer a range key instead of a ref key when the range key can use more columns than the ref key (which only can use columns with =). For example, the following type of queries should now be faster: `SELECT * from key_part_1=const and key_part_2 > const2`
- Fixed bug that a change of all VARCHAR columns to CHAR columns didn't change row type from dynamic to fixed.
- Disabled floating-point exceptions for FreeBSD to fix core dump when doing `SELECT FLOOR(POW(2,63))`.
- Renamed **mysqld** startup option from `--delay-key-write` to `--delay-key-write-for-all-tables`.
- Added `read-next-on-key` to HEAP tables. This should fix all problems with HEAP tables when using non-UNIQUE keys.
- Added option to print default arguments to all clients.
- Added `--log-slow-queries` option to **mysqld** to log all queries that take a long time to a separate log file with a time indicating how long the query took.
- Fixed core dump when doing `WHERE key_col=RAND(...)`.
- Fixed optimization bug in `SELECT ... LEFT JOIN ... key_col IS NULL`, when `key_col` could contain NULL values.
- Fixed problem with 8-bit characters as separators in `LOAD DATA INFILE`.

## D.4.53. Changes in release 3.23.8 (02 Jan 2000)

- Fixed problem when handling indexfiles larger than 8GB.
- Added latest patches to MIT-pthreads for NetBSD.

- Fixed problem with time zones that are < GMT - 11.
- Fixed a bug when deleting packed keys in NISAM.
- Fixed problem with ISAM when doing some ORDER BY ... DESC queries.
- Fixed bug when doing a join on a text key which didn't cover the whole key.
- Option --delay-key-write didn't enable delayed key writing.
- Fixed update of TEXT column which involved only case changes.
- Fixed that INSERT DELAYED doesn't update timestamps that are given.
- Added function YEARWEEK ( ) and options x, X, v and V to DATE\_FORMAT ( ).
- Fixed problem with MAX ( indexed\_column ) and HEAP tables.
- Fixed problem with BLOB NULL keys and LIKE "prefix%".
- Fixed problem with MyISAM and fixed-length rows < 5 bytes.
- Fixed problem that could cause MySQL to touch freed memory when doing very complicated GROUP BY queries.
- Fixed core dump if you got a crashed table where an ENUM field value was too big.

## D.4.54. Changes in release 3.23.7 (10 Dec 1999)

- Fixed workaround under Linux to avoid problems with pthread\_mutex\_timedwait ( ), which is used with INSERT DELAYED. See Section 2.12.1, "Linux Notes".
- Fixed that one get a 'disk full' error message if one gets disk full when doing sorting (instead of waiting until we got more disk space).
- Fixed a bug in MyISAM with keys > 250 characters.
- In MyISAM one can now do an INSERT at the same time as other threads are reading from the table.
- Added max\_write\_lock\_count variable to **mysqld** to force a READ lock after a certain number of WRITE locks.
- Inverted flag delay\_key\_write on show variables.
- Renamed concurrency variable to thread\_concurrency.
- The following functions are now multi-byte-safe: LOCATE ( substr , str ), POSITION ( substr IN str ), LOCATE ( substr , str , pos ), INSTR ( str , substr ), LEFT ( str , len ), RIGHT ( str , len ), SUBSTRING ( str , pos , len ), SUBSTRING ( str FROM pos FOR len ), MID ( str , pos , len ), SUBSTRING ( str , pos ), SUBSTRING ( str FROM pos ), SUBSTRING\_INDEX ( str , delim , count ), RTRIM ( str ), TRIM ( [ BOTH | TRAILING ] [ remstr ] FROM str ), REPLACE ( str , from\_str , to\_str ), REVERSE ( str ), INSERT ( str , pos , len , newstr ), LCASE ( str ), LOWER ( str ), UCASE ( str ) and UPPER ( str ); patch by Wei He.
- Fix core dump when releasing a lock from a non-existent table.
- Remove locks on tables before starting to remove duplicates.
- Added option FULL to SHOW PROCESSLIST.

- Added option `--verbose` to **mysqladmin**.
- Fixed problem when automatically converting HEAP to MyISAM.
- Fixed bug in HEAP tables when doing insert + delete + insert + scan the table.
- Fixed bugs on Alpha with `REPLACE ( )` and `LOAD DATA INFILE`.
- Added `interactive_timeout` variable to **mysqld**.
- Changed the argument to `mysql_data_seek ( )` from `ulong` to `ulonglong`.

## D.4.55. Changes in release 3.23.6 (15 Nov 1999)

- Added `-O lower_case_table_names={0|1}` option to **mysqld** to allow users to force table names to lowercase.
- Added `SELECT ... INTO DUMPFILE`.
- Added `--ansi` option to **mysqld** to make some functions standard SQL compatible.
- Temporary table names now start with `#sql`.
- Added quoting of identifiers with `` ( " in --ansi mode)`.
- Changed to use `snprintf ( )` when printing floats to avoid some buffer overflows on FreeBSD.
- Made `FLOOR ( )` overflow safe on FreeBSD.
- Added `--quote-names` option to **mysqldump**.
- Fixed bug that one could make a part of a `PRIMARY KEY NOT NULL`.
- Fixed `encrypt ( )` to be thread-safe and not reuse buffer.
- Added `mysql_odbc_escape_string ( )` function to support big5 characters in MyODBC.
- Rewrote the storage engine to use classes. This introduces a lot of new code, but make table handling faster and better.
- Added patch by Sasha for user-defined variables.
- Changed that `FLOAT` and `DOUBLE` (without any length modifiers) no longer are fixed decimal point numbers.
- Changed the meaning of `FLOAT ( X )`: Now this is the same as `FLOAT` if  $X \leq 24$  and a `DOUBLE` if  $24 < X \leq 53$ .
- `DECIMAL ( X )` is now an alias for `DECIMAL ( X , 0 )` and `DECIMAL` is now an alias for `DECIMAL ( 10 , 0 )`. The same goes for `NUMERIC`.
- Added option `ROW_FORMAT={DEFAULT | DYNAMIC | FIXED | COMPRESSED}` to `CREATE_TABLE`.
- `DELETE FROM tbl_name` didn't work on temporary tables.
- Changed function `CHAR_LENGTH ( )` to be multi-byte character safe.
- Added function `ORD ( string )`.

## D.4.56. Changes in release 3.23.5 (20 Oct 1999)

- Fixed some Y2K problems in the new date handling in 3.23.
- Fixed problem with `SELECT DISTINCT ... ORDER BY RAND()`.
- Added patches by Sergei A. Golubchik for text searching on the MyISAM level.
- Fixed cache overflow problem when using full joins without keys.
- Fixed some configure issues.
- Some small changes to make parsing faster.
- Adding a column after the last field with `ALTER TABLE` didn't work.
- Fixed problem when using an `AUTO_INCREMENT` column in two keys
- With MyISAM, you now can have an `AUTO_INCREMENT` column as a key sub part: `CREATE TABLE foo (a INT NOT NULL AUTO_INCREMENT, b CHAR(5), PRIMARY KEY (b,a))`
- Fixed bug in MyISAM with packed char keys that could be NULL.
- `AS` on field name with `CREATE TABLE tbl_name SELECT ...` didn't work.
- Allow use of `NATIONAL` and `NCHAR` when defining character columns. This is the same as not using `BINARY`.
- Don't allow NULL columns in a `PRIMARY KEY` (only in `UNIQUE` keys).
- Clear `LAST_INSERT_ID()` if one uses this in ODBC: `WHERE auto_increment_column IS NULL`. This seems to fix some problems with Access.
- `SET SQL_AUTO_IS_NULL=0|1` now turns on/off the handling of searching for the last inserted row with `WHERE auto_increment_column IS NULL`.
- Added new variable `concurrency` to **mysqld** for Solaris.
- Added `--relative` option to **mysqladmin** to make `extended-status` more useful to monitor changes.
- Fixed bug when using `COUNT(DISTINCT ...)` on an empty table.
- Added support for the Chinese character set GBK.
- Fixed problem with `LOAD DATA INFILE` and BLOB columns.
- Added bit operator `~` (negation).
- Fixed problem with user-defined functions.

## D.4.57. Changes in release 3.23.4 (28 Sep 1999)

- Inserting a `DATETIME` into a `TIME` column no longer try to store 'days' in it.
- Fixed problem with storage of float/double on little endian machines. (This affected `SUM()`.)
- Added connect timeout on TCP/IP connections.
- Fixed problem with `LIKE "%"` on an index that may have NULL values.

- `REVOKE ALL PRIVILEGES` didn't revoke all privileges.
- Allow creation of temporary tables with same name as the original table.
- When granting an account a `GRANT` option for a database, the account couldn't grant privileges to other users.
- New statement: `SHOW GRANTS FOR user` (by Sinisa).
- New `date_add` syntax: `date/datetime + INTERVAL # interval_type`. By Joshua Chamas.
- Fixed privilege check for `LOAD DATA REPLACE`.
- Automatic fixing of broken include files on Solaris 2.7
- Some configure issues to fix problems with big filesystem detection.
- `REGEXP` is now case-insensitive if you use non-binary strings.

## D.4.58. Changes in release 3.23.3 (13 Sep 1999)

- Added patches for MIT-pthreads on NetBSD.
- Fixed range bug in MyISAM.
- `ASC` is now the default again for `ORDER BY`.
- Added `LIMIT` to `UPDATE`.
- Added `mysql_change_user()` function to the MySQL C API.
- Added character set to `SHOW VARIABLES`.
- Added support of `--[whitespace]` comments.
- Allow `INSERT INTO tbl_name VALUES ()`, that is, you may now specify an empty value list to insert a row in which each column is set to its default value.
- Changed `SUBSTRING(text FROM pos)` to conform to standard SQL. (Before this construct returned the rightmost `pos` characters.)
- `SUM()` with `GROUP BY` returned 0 on some systems.
- Changed output for `SHOW TABLE STATUS`.
- Added `DELAY_KEY_WRITE` option to `CREATE TABLE`.
- Allow `AUTO_INCREMENT` on any key part.
- Fixed problem with `YEAR(NOW())` and `YEAR(CURDATE())`.
- Added `CASE` construct.
- New `COALESCE()` function.

## D.4.59. Changes in release 3.23.2 (09 Aug 1999)

- Fixed range optimizer bug: `SELECT * FROM tbl_name WHERE key_part1 >=`

`const AND (key_part2 = const OR key_part2 = const)`. The bug was that some rows could be duplicated in the result.

- Running **myisamchk** without `-a` updated the index distribution incorrectly.
- `SET SQL_LOW_PRIORITY_UPDATES=1` was causing a parse error.
- You can now update index columns that are used in the WHERE clause. `UPDATE tbl_name SET KEY=KEY+1 WHERE KEY > 100`
- Date handling should now be a bit faster.
- Added handling of fuzzy dates (dates where day or month is 0), such as '1999-01-00'.
- Fixed optimization of `SELECT ... WHERE key_part1=const1 AND key_part_2=const2 AND key_part1=const4 AND key_part2=const4`; index-type should be range instead of ref.
- Fixed **egcs** 1.1.2 optimizer bug (when using BLOB values) on Linux Alpha.
- Fixed problem with `LOCK TABLES` combined with `DELETE FROM table`.
- MyISAM tables now allow keys on NULL and BLOB/TEXT columns.
- The following join is now much faster: `SELECT ... FROM t1 LEFT JOIN t2 ON ... WHERE t2.not_null_column IS NULL`.
- `ORDER BY` and `GROUP BY` can be done on functions.
- Changed handling of 'const\_item' to allow handling of `ORDER BY RAND()`.
- Indexes are now used for `WHERE key_column = function`.
- Indexes are now used for `WHERE key_column = col_name` even if the columns are not identically packed.
- Indexes are now used for `WHERE col_name IS NULL`.
- Changed heap tables to be stored in low\_byte\_first order (to make it easy to convert to MyISAM tables)
- Automatic change of HEAP temporary tables to MyISAM tables in case of "table is full" errors.
- Added `--init-file=file_name` option to **mysqld**.
- Added `COUNT(DISTINCT value, [value, ...])`.
- `CREATE TEMPORARY TABLE` now creates a temporary table, in its own namespace, that is automatically deleted if connection is dropped.
- New reserved words (required for CASE): `CASE`, `THEN`, `WHEN`, `ELSE` and `END`.
- New functions `EXPORT_SET()` and `MD5()`.
- Support for the GB2312 Chinese character set.

## D.4.60. Changes in release 3.23.1 (08 Jul 1999)

- Fixed some compilation problems.

## D.4.61. Changes in release 3.23.0 (05 Jul 1999: Alpha)

- A new storage engine library (MyISAM) with a lot of new features. See Section 14.1, “The MyISAM Storage Engine”.
- You can create in-memory HEAP tables which are extremely fast for lookups.
- Support for big files (63-bit) on OSs that support big files.
- New function `LOAD_FILE(filename)` to get the contents of a file as a string value.
- New `<=>` operator that acts as `=` but returns TRUE if both arguments are NULL. This is useful for comparing changes between tables.
- Added the ODBC 3.0 `EXTRACT(interval FROM datetime)` function.
- Columns defined as `FLOAT(X)` are not rounded on storage and may be in scientific notation (1.0 E+10) when retrieved.
- REPLACE is now faster than before.
- Changed LIKE character comparison to behave as `=`; This means that `'e' LIKE 'é'` is now true. (If the line doesn't display correctly, the latter 'e' is a French 'e' with an acute accent above.)
- `SHOW TABLE STATUS` returns a lot of information about the tables.
- Added LIKE to the `SHOW STATUS` command.
- Added `Privileges` column to `SHOW COLUMNS`.
- Added `Packed` and `Comment` columns to `SHOW INDEX`.
- Added comments to tables (with `CREATE TABLE ... COMMENT 'xxx'`).
- Added UNIQUE, as in `CREATE TABLE tbl_name (col INT NOT NULL UNIQUE)`
- New create syntax: `CREATE TABLE tbl_name SELECT ...`
- New create syntax: `CREATE TABLE IF NOT EXISTS ...`
- Allow creation of `CHAR(0)` columns.
- `DATE_FORMAT()` now requires `'%'` before any format character.
- DELAYED is now a reserved word (sorry about that :()).
- An example procedure is added: `analyse`, file: `sql_analyse.c`. This describes the data in your query. Try the following:

```
SELECT ... FROM ...
WHERE ... PROCEDURE ANALYSE([max_elements],[max_memory])
```

This procedure is extremely useful when you want to check the data in your table!

- BINARY cast to force a string to be compared in case-sensitive fashion.
- Added `--skip-show-database` option to **mysqld**.
- Check whether a row has changed in an UPDATE now also works with BLOB/TEXT columns.
- Added the INNER join syntax. **Note:** This made INNER a reserved word!
- Added support for netmasks to the hostname in the MySQL grant tables. You can specify a net-

mask using the IP/NETMASK syntax.

- If you compare a NOT NULL DATE/DATETIME column with IS NULL, this is changed to a compare against 0 to satisfy some ODBC applications. (By <shreeve@uci.edu>.)
- NULL IN ( . . . ) now returns NULL instead of 0. This ensures that null\_column NOT IN ( . . . ) doesn't match NULL values.
- Fix storage of floating-point values in TIME columns.
- Changed parsing of TIME strings to be more strict. Now the fractional second part is detected (and currently skipped). The following formats are supported:
  - [[DAYS] [H]H:]MM:]SS[.fraction]
  - [[[[[H]H]H]H]MM]SS[.fraction]
- Detect (and ignore) fractional second part from DATETIME.
- Added the LOW\_PRIORITY attribute to LOAD DATA INFILE.
- The default index name now uses the same case as the column name on which the index name is based.
- Changed default number of connections to 100.
- Use bigger buffers when using LOAD DATA INFILE.
- DECIMAL(x,y) now works according to standard SQL.
- Added aggregate user-defined functions. Thanks to Andreas F. Bobak (<bobak@relog.ch>) for this!
- LAST\_INSERT\_ID() is now updated for INSERT INTO . . . SELECT.
- Some small changes to the join table optimizer to make some joins faster.
- SELECT DISTINCT is much faster; it uses the new UNIQUE functionality in MyISAM. One difference compared to MySQL 3.22 is that the output of DISTINCT is no longer sorted.
- All C client API macros are now functions to make shared libraries more reliable. Because of this, you can no longer call mysql\_num\_fields() on a MYSQL object, you must use mysql\_field\_count() instead.
- Added use of LIBWRAP; patch by Henning P. Schmiedehausen.
- Don't allow AUTO\_INCREMENT for other than numerical columns.
- Using AUTO\_INCREMENT now automatically makes the column NOT NULL.
- Show NULL as the default value for AUTO\_INCREMENT columns.
- Added SQL\_BIG\_RESULT; SQL\_SMALL\_RESULT is now default.
- Added a shared library RPM. This enhancement was contributed by David Fox (<dsfox@cogsci.ucsd.edu>).
- Added --enable-large-files and --disable-large-files options to **configure**. See `configure.in` for some systems where this is automatically turned off because of broken implementations.
- Upgraded readline to 4.0.
- New CREATE TABLE options: PACK\_KEYS and CHECKSUM.

- Added `--default-table-type` option to **mysqld**.

## D.5. Changes in release 3.22.x (Old; discontinued)

The 3.22 version has faster and safer connect code than version 3.21, as well as a lot of new nice enhancements. As there aren't really any major changes, upgrading from 3.21 to 3.22 should be very easy and painless. See Section 2.10.5, "Upgrading from Version 3.21 to 3.22".

### D.5.1. Changes in release 3.22.35

- Fixed problem with `STD( )`.
- Merged changes from the newest `ISAM` library from 3.23.
- Fixed problem with `INSERT DELAYED`.
- Fixed a bug core dump when using a `LEFT JOIN/STRAIGHT_JOIN` on a table with only one row.

### D.5.2. Changes in release 3.22.34

- Fixed problem with `GROUP BY` on `TINYBLOB` columns; this caused bugzilla to not show rows in some queries.
- Had to do total recompile of the Windows binary version as `VC++` didn't compile all relevant files for 3.22.33 :(

### D.5.3. Changes in release 3.22.33

- Fixed problems in Windows when locking tables with `LOCK TABLE`.
- Quicker kill of `SELECT DISTINCT` queries.

### D.5.4. Changes in release 3.22.32 (14 Feb 2000)

- Fixed problem when storing numbers in timestamps.
- Fix problem with time zones that have half hour offsets.
- Added **mysqlhotcopy**, a fast online hot-backup utility for local MySQL databases. By Tim Bunce.
- New more secure **mysqlaccess**. Thanks to Steve Harvey for this.
- Fixed security problem in the protocol regarding password checking. (CVE-2000-0148 [<http://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2000-0148>])
- Fixed problem that affected queries that did arithmetic on `GROUP` functions.
- Fixed a bug in the `ISAM` code when deleting rows on tables with packed indexes.

## D.5.5. Changes in release 3.22.31

- A few small fixes for the Windows version.

## D.5.6. Changes in release 3.22.30 (11 Jan 2000)

- Fixed optimizer problem on `SELECT` when using many overlapping indexes.
- Disabled floating-point exceptions for FreeBSD to fix core dump when doing `SELECT FLOOR( POW( 2 , 63 ) )`.
- Added print of default arguments options to all clients.
- Fixed critical problem with the `WITH GRANT OPTION` option.
- Fixed non-critical Y2K problem when writing short date to log files.

## D.5.7. Changes in release 3.22.29 (02 Jan 2000)

- Upgraded the `configure` and `include` files to match the latest 3.23 version. This should increase portability and make it easier to build shared libraries.
- Added latest patches to MIT-pthreads for NetBSD.
- Fixed problem with time zones that are `< GMT -11`.
- Fixed a bug when deleting packed keys in NISAM.
- Fixed problem that could cause MySQL to touch freed memory when doing very complicated `GROUP BY` queries.
- Fixed core dump if you got a crashed table where an `ENUM` field value was too big.
- Added `mysqlshutdown.exe` and `mysqlwatch.exe` to the Windows distribution.
- Fixed problem when doing `ORDER BY` on a reference key.
- Fixed that `INSERT DELAYED` doesn't update timestamps that are given.

## D.5.8. Changes in release 3.22.28 (20 Oct 1999)

- Fixed problem with `LEFT JOIN` and `COUNT( )` on a column which was declared `NULL +` and it had a `DEFAULT` value.
- Fixed core dump problem when using `CONCAT( )` in a `WHERE` clause.
- Fixed problem with `AVG( )` and `STD( )` with `NULL` values.

## D.5.9. Changes in release 3.22.27 (05 Oct 1999)

- Fixed prototype in `my_ctype.h` when using other character sets.
- Some `configure` issues to fix problems with big filesystem detection.

- Fixed problem when sorting on big BLOB columns.
- `ROUND( )` now works on Windows.

## D.5.10. Changes in release 3.22.26 (16 Sep 1999)

- Fixed core dump with empty BLOB/TEXT column argument to `REVERSE( )`.
- Extended `/ * ! * /` with version numbers.
- Changed `SUBSTRING(text FROM pos)` to conform to standard SQL. (Before this construct returned the rightmost 'pos' characters.)
- Fixed problem with `LOCK TABLES` combined with `DELETE FROM table`
- Fixed problem that `INSERT ... SELECT` didn't use `BIG_TABLES`.
- `SET SQL_LOW_PRIORITY_UPDATES=#` didn't work.
- Password wasn't updated correctly if privileges didn't change on: `GRANT ... IDENTIFIED BY`
- Fixed range optimizer bug in `SELECT * FROM tbl_name WHERE key_part1 >= const AND (key_part2 = const OR key_part2 = const)`.
- Fixed bug in compression key handling in ISAM.

## D.5.11. Changes in release 3.22.25 (07 Jun 1999)

- Fixed some small problems with the installation.

## D.5.12. Changes in release 3.22.24 (05 Jul 1999)

- `DATA` is no longer a reserved word.
- Fixed optimizer bug with tables with only one row.
- Fixed bug when using `LOCK TABLES tbl_name READ; FLUSH TABLES;`
- Applied some patches for HP-UX.
- `isamchk` should now work on Windows.
- Changed `configure` to not use big file handling on Linux as this crashes some Red Hat 6.0 systems

## D.5.13. Changes in release 3.22.23 (08 Jun 1999)

- Upgraded to use Autoconf 2.13, Automake 1.4 and `libtool` 1.3.2.
- Better support for SCO in `configure`.
- Added option `--defaults-file=file_name` to option file handling to force use of only one specific option file.

- Extended CREATE syntax to ignore MySQL 3.23 keywords.
- Fixed deadlock problem when using INSERT DELAYED on a table locked with LOCK TABLES.
- Fixed deadlock problem when using DROP TABLE on a table that was locked by another thread.
- Add logging of GRANT/REVOKE commands in the update log.
- Fixed **isamchk** to detect a new error condition.
- Fixed bug in NATURAL LEFT JOIN.

### D.5.14. Changes in release 3.22.22 (30 Apr 1999)

- Fixed problem in the C API when you called mysql\_close() directly after mysql\_init().
- Better client error message when you can't open socket.
- Fixed delayed\_insert\_thread counting when you couldn't create a new delayed\_insert thread.
- Fixed bug in CONCAT( ) with many arguments.
- Added patches for DEC 3.2 and SCO.
- Fixed path-bug when installing MySQL as a service on NT.
- MySQL on Windows is now compiled with VC++ 6.0 instead of with VC++ 5.0.
- New installation setup for MySQL on Windows.

### D.5.15. Changes in release 3.22.21 (04 Apr 1999)

- Fixed problem with DELETE FROM TABLE when table was locked by another thread.
- Fixed bug in LEFT JOIN involving empty tables.
- Changed the mysql .db column from CHAR( 32 ) to CHAR( 60 ).
- MODIFY and DELAYED are no longer reserved words.
- Fixed a bug when storing days in a TIME column.
- Fixed a problem with Host '...' is not allowed to connect to this MySQL server after one had inserted a new MySQL user with a GRANT command.
- Changed to use TCP\_NODELAY also on Linux (should give faster TCP/IP connections).

### D.5.16. Changes in release 3.22.20 (18 Mar 1999)

- Fixed STD( ) for big tables when result should be 0.
- The update log didn't have newlines on some operating systems.

- `INSERT DELAYED` had some garbage at end in the update log.

## D.5.17. Changes in release 3.22.19 (01 Mar 1999)

- Fixed bug in `mysql_install_db` (from 3.22.17).
- Changed default key cache size to 8MB.
- Fixed problem with queries that needed temporary tables with BLOB columns.

## D.5.18. Changes in release 3.22.18 (26 Feb 1999)

- Fixes a fatal problem in 3.22.17 on Linux; after shutdown not all threads died properly.
- Added option `-O flush_time=#` to `mysqld`. This is mostly useful on Windows and tells how often MySQL should close all unused tables and flush all updated tables to disk.
- Fixed problem that a `VARCHAR` column compared with `CHAR` column didn't use keys efficiently.

## D.5.19. Changes in release 3.22.17 (22 Feb 1999: Production)

- Fixed a core dump problem when using `--log-update` and connecting without a default database.
- Fixed some `configure` and portability problems.
- Using `LEFT JOIN` on tables that had circular dependencies caused `mysqld` to hang forever.

## D.5.20. Changes in release 3.22.16 (05 Feb 1999)

- `mysqladmin processlist` could kill the server if a new user logged in.
- `DELETE FROM tbl_name WHERE key_column=col_name` didn't find any matching rows. Fixed.
- `DATE_ADD(column, ...)` didn't work.
- `INSERT DELAYED` could deadlock with `status upgrading lock`.
- Extended `ENCRYPT()` to take longer salt strings than 2 characters.
- `longlong2str` is now much faster than before. For Intel x86 platforms, this function is written in optimized assembler.
- Added the `MODIFY` keyword to `ALTER TABLE`.

## D.5.21. Changes in release 3.22.15 (27 Jan 1999)

- `GRANT` used with `IDENTIFIED BY` didn't take effect until privileges were flushed.
- Name change of some variables in `SHOW STATUS`.
- Fixed problem with `ORDER BY` with 'only index' optimization when there were multiple key definitions for a used column.
- `DATE` and `DATETIME` columns are now up to 5 times faster than before.
- `INSERT DELAYED` can be used to let the client do other things while the server inserts rows into a table.
- `LEFT JOIN USING (col1, col2)` didn't work if one used it with tables from 2 different databases.
- `LOAD DATA LOCAL INFILE` didn't work in the Unix version because of a missing file.
- Fixed problems with `VARCHAR/BLOB` on very short rows (< 4 bytes); error 127 could occur when deleting rows.
- Updating `BLOB/TEXT` through formulas didn't work for short (< 256 char) strings.
- When you did a `GRANT` on a new host, **mysqld** could die on the first connect from this host.
- Fixed bug when one used `ORDER BY` on column name that was the same name as an alias.
- Added `BENCHMARK(loop_count, expression)` function to time expressions.

## D.5.22. Changes in release 3.22.14 (01 Jan 1999: Gamma)

- Allow empty arguments to **mysqld** to make it easier to start from shell scripts.
- Setting a `TIMESTAMP` column to `NULL` didn't record the timestamp value in the update log.
- Fixed lock handler bug when one did `INSERT INTO TABLE ... SELECT ... GROUP BY`.
- Added a patch for `localtime_r()` on Windows so that it no longer crashes if your date is > 2039, but instead returns a time of all zero.
- Names for user-defined functions are no longer case-sensitive.
- Added escape of `^Z` (ASCII 26) to `\Z` as `^Z` doesn't work with pipes on Windows.
- **mysql\_fix\_privileges** adds a new column to the `mysql.func` to support aggregate user-defined functions in future MySQL releases.

## D.5.23. Changes in release 3.22.13 (16 Dec 1998)

- Saving `NOW()`, `CURDATE()` or `CURTIME()` directly in a column didn't work.
- `SELECT COUNT(*) ... LEFT JOIN ...` didn't work with no `WHERE` part.
- Updated `config.guess` to allow MySQL to configure on UnixWare 7.1.x.
- Changed the implementation of `pthread_cond()` on the Windows version. `get_lock()` now correctly times out on Windows!

## D.5.24. Changes in release 3.22.12 (09 Dec 1998)

- Fixed problem when using `DATE_ADD()` and `DATE_SUB()` in a `WHERE` clause.
- You can now set the password for a user with the `GRANT ... TO user IDENTIFIED BY 'password'` syntax.
- Fixed bug in `GRANT` checking with `SELECT` on many tables.
- Added missing file **mysql\_fix\_privilege\_tables** to the RPM distribution. This is not run by default because it relies on the client package.
- Added option `SQL_SMALL_RESULT` to `SELECT` to force use of fast temporary tables when you know that the result set is small.
- Allow use of negative real numbers without a decimal point.
- Day number is now adjusted to maximum days in month if the resulting month after `DATE_ADD/DATE_SUB()` doesn't have enough days.
- Fix that `GRANT` compares columns in case-insensitive fashion.
- Fixed a bug in `sql_list.h` that made `ALTER TABLE` dump core in some contexts.
- The hostname in `user@hostname` can now include '.' and '-' without quotes in the context of the `GRANT`, `REVOKE` and `SET PASSWORD FOR ...` statements.
- Fix for **isamchk** for tables which need big temporary files.

## D.5.25. Changes in release 3.22.11 (24 Nov 1998)

- **Important:** You must run the **mysql\_fix\_privilege\_tables** script when you upgrade to this version! This is needed because of the new `GRANT` system. If you don't do this, you get Access denied when you try to use `ALTER TABLE`, `CREATE INDEX`, or `DROP INDEX`.
- `GRANT` to allow/deny users table and column access.
- Changed `USER()` to return a value in `user@host` format. Formerly it returned only `user`.
- Changed the syntax for how to set `PASSWORD` for another user.
- New command `FLUSH STATUS` that resets most status variables to zero.
- New status variables: `aborted_threads`, `aborted_connects`.
- New option variable: `connection_timeout`.
- Added support for Thai sorting (by Pruet Boonma <pruet@ds90.intanon.nectec.or.th>).
- Slovak and Japanese error messages.
- Configuration and portability fixes.
- Added option `SET SQL_WARNINGS=1` to get a warning count also for simple (single-row) inserts.
- MySQL now uses `SIGTERM` instead of `SIGQUIT` with shutdown to work better on FreeBSD.
- Added option `\G` (print vertically) to **mysql**.

- `SELECT HIGH_PRIORITY ...` killed **mysqld**.
- `IS NULL` on a `AUTO_INCREMENT` column in a `LEFT JOIN` didn't work as expected.
- New function `MAKE_SET()`.

## D.5.26. Changes in release 3.22.10 (04 Nov 1998)

- **mysql\_install\_db** no longer starts the MySQL server! You should start **mysqld** with **safe\_mysqld** after installing it! The MySQL RPM, however, starts the server as before.
- Added `--bootstrap` option to **mysqld** and recoded **mysql\_install\_db** to use it. This makes it easier to install MySQL with RPMs.
- Changed `+`, `-` (sign and minus), `*`, `/`, `%`, `ABS()` and `MOD()` to be `BIGINT` aware (64-bit safe).
- Fixed a bug in `ALTER TABLE` that caused **mysqld** to crash.
- MySQL now always reports the conflicting key values when a duplicate key entry occurs. (Before this was only reported for `INSERT`.)
- New syntax: `INSERT INTO tbl_name SET col_name=value, col_name=value, ...`
- Most errors in the `.err` log are now prefixed with a time stamp.
- Added option `MYSQL_INIT_COMMAND` to `mysql_options()` to make a query on connect or reconnect.
- Added option `MYSQL_READ_DEFAULT_FILE` and `MYSQL_READ_DEFAULT_GROUP` to `mysql_options()` to read the following parameters from the MySQL option files: `port`, `socket`, `compress`, `password`, `pipe`, `timeout`, `user`, `init-command`, `host` and `database`.
- Added `maybe_null` to the UDF structure.
- Added option `IGNORE` to `INSERT` statements with many rows.
- Fixed some problems with sorting of the `koi8` character sets; users of `koi8` **must** run **isamchk -rq** on each table that has an index on a `CHAR` or `VARCHAR` column.
- New script **mysql\_setpermission**, by Luuk de Boer. It allows easy creation of new users with permissions for specific databases.
- Allow use of hexadecimal strings (`0x...`) when specifying a constant string (like in the column separators with `LOAD DATA INFILE`).
- Ported to OS/2 (thanks to Antony T. Curtis <antony.curtis@olcs.net>).
- Added more variables to `SHOW STATUS` and changed format of output to be like `SHOW VARIABLES`.
- Added `extended-status` command to **mysqladmin** which shows the new status variables.

## D.5.27. Changes in release 3.22.9 (19 Oct 1998)

- `SET SQL_LOG_UPDATE=0` caused a lockup of the server.
- New SQL statement: `FLUSH [ TABLES | HOSTS | LOGS | PRIVILEGES ] [,`

...]

- New SQL statement: `KILL thread_id`.
- Added casts and changed include files to make MySQL easier to compile on AIX and DEC OSF/1 4.x
- Fixed conversion problem when using `ALTER TABLE` from a `INT` to a short `CHAR ( )` column.
- Added `SELECT HIGH_PRIORITY`; this gets a lock for the `SELECT` even if there is a thread waiting for another `SELECT` to get a `WRITE LOCK`.
- Moved `wild_compare()` to string class to be able to use `LIKE` on `BLOB/TEXT` columns with `\0`.
- Added `ESCAPE` option to `LIKE`.
- Added a lot more output to **mysqladmin debug**.
- You can now start **mysqld** on Windows with the `--flush` option. This flushes all tables to disk after each update. This makes things much safer on the Windows platforms but also **much** slower.

## D.5.28. Changes in release 3.22.8 (06 Oct 1998)

- Czech character sets should now work much better.
- `DATE_ADD()` and `DATE_SUB()` didn't work with group functions.
- **mysql** now also tries to reconnect on `USE database` commands.
- Fix problem with `ORDER BY` and `LEFT JOIN` and `const` tables.
- Fixed problem with `ORDER BY` if the first `ORDER BY` column was a key and the rest of the `ORDER BY` columns wasn't part of the key.
- Fixed a big problem with `OPTIMIZE TABLE`.
- MySQL clients on NT now by default first try to connect with named pipes and after this with TCP/IP.
- Fixed a problem with `DROP TABLE` and **mysqladmin shutdown** on Windows (a fatal bug from 3.22.6).
- Fixed problems with `TIME` columns and negative strings.
- Added an extra thread signal loop on shutdown to avoid some error messages from the client.
- MySQL now uses the next available number as extension for the update log file.
- Added patches for UNIXWARE 7.

## D.5.29. Changes in release 3.22.7 (21 Sep 1998: Beta)

- Added `LIMIT` clause for the `DELETE` statement.
- You can now use the `/*! ... */` syntax to hide MySQL-specific keywords when you write portable code. MySQL parses the code inside the comments as if the surrounding `/*!` and `*/` comment characters didn't exist.

- `OPTIMIZE TABLE tbl_name` can now be used to reclaim disk space after many deletes. Currently, this uses `ALTER TABLE` to regenerate the table, but in the future it will use an integrated **isamchk** for more speed.
- Upgraded **libtool** to make the configuration process more portable.
- Fixed slow `UPDATE` and `DELETE` operations when using `DATETIME` or `DATE` keys.
- Changed optimizer to make it better at deciding when to do a full join and when using keys.
- You can now use **mysqladmin proc** to display information about your own threads. Only users with the `PROCESS` privilege can get information about all threads. (In 4.0.2, you need the `SUPER` privilege for this.)
- Added handling of formats `YYMMDD`, `YYYYMMDD`, `YYMMDDHHMMSS` for numbers when using `DATETIME` and `TIMESTAMP` types. (Formerly these formats only worked with strings.)
- Added connect option `CLIENT_IGNORE_SPACE` to allow use of spaces after function names and before `'` (Powerbuilder requires this). This makes all function names reserved words.
- Added the `--log-long-format` option to **mysqld** to enable timestamps and `INSERT_IDS` in the update log.
- Added `--where` option to **mysqldump** (patch by Jim Faucette).
- The lexical analyzer now uses "perfect hashing" for faster parsing of SQL statements.

## D.5.30. Changes in release 3.22.6 (31 Aug 1998)

- Faster **mysqldump**.
- For the `LOAD DATA INFILE` statement, you can now use the new `LOCAL` keyword to read the file from the client. **mysqlimport** automatically uses `LOCAL` when importing with the TCP/IP protocol.
- Fixed small optimize problem when updating keys.
- Changed makefiles to support shared libraries.
- MySQL-NT can now use named pipes, which means that you can now use MySQL-NT without having to install TCP/IP.

## D.5.31. Changes in release 3.22.5 (20 Aug 1998: Alpha)

- All table lock handing is changed to avoid some very subtle deadlocks when using `DROP TABLE`, `ALTER TABLE`, `DELETE FROM TABLE` and **mysqladmin flush-tables** under heavy usage. Changed locking code to get better handling of locks of different types.
- Updated DBI to 1.00 and DBD to 1.2.0.
- Added a check that the error message file contains error messages suitable for the current version of **mysqld**. (To avoid errors if you accidentally try to use an old error message file.)
- All count structures in the client (`affected_rows()`, `insert_id()`, ...) are now of type `BIGINT` to allow 64-bit values to be used. This required a minor change in the MySQL protocol which should affect only old clients when using tables with `AUTO_INCREMENT` values > 16MB.
- The return type of `mysql_fetch_lengths()` has changed from `uint *` to `ulong *`.

This may give a warning for old clients but should work on most machines.

- Change `mysys` and `dbug` libraries to allocate all thread variables in one struct. This makes it easier to make a threaded `libmysql.dll` library.
- Use the result from `gethostname()` (instead of `uname()`) when constructing `.pid` file-names.
- New better compressed client/server protocol.
- `COUNT()`, `STD()` and `AVG()` are extended to handle more than 4GB rows.
- You can now store values in the range `-838:59:59 <= x <= 838:59:59` in a `TIME` column.
- **Warning: Incompatible change!!** If you set a `TIME` column to too short a value, MySQL now assumes the value is given as: `[ [D ]HH: ]MM: ]SS` instead of `HH[ :MM[ :SS ]]`.
- `TIME_TO_SEC()` and `SEC_TO_TIME()` can now handle negative times and hours up to 32767.
- Added new option `SET SQL_LOG_UPDATE={0|1}` to allow users with the `PROCESS` privilege to bypass the update log. (Modified patch from Sergey A Mukhin <violet@rosnet.net>.)
- Fixed fatal bug in `LPAD()`.
- Initialize line buffer in `mysql.cc` to make `BLOB` reading from pipes safer.
- Added `-O max_connect_errors=#` option to **mysqld**. Connect errors are now reset for each correct connection.
- Increased the default value of `max_allowed_packet` to 1M in **mysqld**.
- Added `--low-priority-updates` option to **mysqld**, to give table-modifying operations (`INSERT`, `REPLACE`, `UPDATE`, `DELETE`) lower priority than retrievals. You can now use `{INSERT | REPLACE | UPDATE | DELETE} LOW_PRIORITY ...`. You can also use `SET SQL_LOW_PRIORITY_UPDATES={0|1}` to change the priority for one thread. One side effect is that `LOW_PRIORITY` is now a reserved word. :(
- Add support for `INSERT INTO table ... VALUES(...),(...),(...)`, to allow inserting multiple rows with a single statement.
- `INSERT INTO tbl_name` is now also cached when used with `LOCK TABLES`. (Previously only `INSERT ... SELECT` and `LOAD DATA INFILE` were cached.)
- Allow `GROUP BY` functions with `HAVING`:  

```
mysql> SELECT col FROM table GROUP BY col HAVING COUNT(*)>0;
```
- **mysqld** now ignores trailing `'` characters in queries. This is to make it easier to migrate from some other SQL servers that require the trailing `'`.
- Fix for corrupted fixed-format output generated by `SELECT INTO OUTFILE`.
- **Warning: Incompatible change!** Added Oracle `GREATEST()` and `LEAST()` functions. You must now use these instead of the `MAX()` and `MIN()` functions to get the largest/smallest value from a list of values. These can now handle `REAL`, `BIGINT` and string (`CHAR` or `VARCHAR`) values.
- **Warning: Incompatible change!** `DAYOFWEEK()` had offset 0 for Sunday. Changed the offset to 1.
- Give an error for queries that mix `GROUP BY` columns and fields when there is no `GROUP BY`

specification.

- Added `--vertical` option to **mysql**, for printing results in vertical mode.
- Index-only optimization; some queries are now resolved using only indexes. Until MySQL 4.0, this works only for numeric columns. See Section 7.4.5, “How MySQL Uses Indexes”.
- Lots of new benchmarks.
- A new C API chapter and lots of other improvements in the manual.

## D.5.32. Changes in release 3.22.4 (06 Jul 1998: Beta)

- Added `--tmpdir` option to **mysqld**, for specifying the location of the temporary file directory.
- MySQL now automatically changes a query from an ODBC client:  

```
SELECT ... FROM table WHERE auto_increment_column IS NULL
```

to:  

```
SELECT ... FROM table WHERE auto_increment_column == LAST_INSERT_ID()
```

This allows some ODBC programs (Delphi, Access) to retrieve the newly inserted row to fetch the `AUTO_INCREMENT` value.
- `DROP TABLE` now waits for all users to free a table before deleting it.
- Fixed small memory leak in the new connect protocol.
- New functions `BIN()`, `OCT()`, `HEX()` and `CONV()` for converting between different number bases.
- Added function `SUBSTRING()` with two arguments.
- If you created a table with a record length smaller than 5, you couldn't delete rows from the table.
- Added optimization to remove `const` reference tables from `ORDER BY` and `GROUP BY`.
- **mysqld** now automatically disables system locking on Linux and Windows, and for systems that use MIT-pthreads. You can force the use of locking with the `--enable-external-locking` option.
- Added `--console` option to **mysqld**, to force a console window (for error messages) when using Windows.
- Fixed table locks for Windows.
- Allow '\$' in identifiers.
- Changed name of user-specific configuration file from `my.cnf` to `.my.cnf` (Unix only).
- Added `DATE_ADD()` and `DATE_SUB()` functions.

## D.5.33. Changes in release 3.22.3 (30 Jun 1998)

- Fixed a lock problem (bug in MySQL 3.22.1) when closing temporary tables.

- Added missing `mysql_ping()` to the client library.
- Added `--compress` option to all MySQL clients.
- Changed `byte` to `char` in `mysql.h` and `mysql_com.h`.

## D.5.34. Changes in release 3.22.2

- Searching on multiple constant keys that matched more than 30% of the rows didn't always use the best possible key.
- New functions `<<`, `>>`, `RPAD()` and `LPAD()`.
- You can now save default options (like passwords) in a configuration file (`my.cnf`).
- Lots of small changes to get `ORDER BY` to work when no records are found when using fields that are not in `GROUP BY` (MySQL extension).
- Added `--chroot` option to **mysqld**, to start **mysqld** in a chroot environment (by Nikki Chumakov <nikkic@cityline.ru>).
- Trailing spaces are now ignored when comparing case-sensitive strings; this should fix some problems with ODBC and flag 512!
- Fixed a core dump bug in the range optimizer.
- Added `--one-thread` option to **mysqld**, for debugging with LinuxThreads (or `glibc`). (This replaces the `-T32` flag)
- Added `DROP TABLE IF EXISTS` to prevent an error from occurring if the table doesn't exist.
- `IF` and `EXISTS` are now reserved words (they would have to be sooner or later).
- Added lots of new options to **mysqldump**.
- Server error messages are now in `mysqld_error.h`.
- The client/server protocol now supports compression.
- All bugfixes from MySQL 3.21.32.

## D.5.35. Changes in release 3.22.1 (Jun 1998)

- Added new C API function `mysql_ping()`.
- Added new API functions `mysql_init()` and `mysql_options()`. You now **MUST** call `mysql_init()` before you call `mysql_real_connect()`. You don't have to call `mysql_init()` if you only use `mysql_connect()`.
- Added `mysql_options(..., MYSQL_OPT_CONNECT_TIMEOUT, ...)` so you can set a timeout for connecting to a server.
- Added `--timeout` option to **mysqladmin**, as a test of `mysql_options()`.
- Added `AFTER column` and `FIRST` options to `ALTER TABLE ... ADD columns`. This makes it possible to add a new column at some specific location within a row in an existing table.
- `WEEK()` now takes an optional argument to allow handling of weeks when the week starts on

Monday (some European countries). By default, `WEEK ( )` assumes the week starts on Sunday.

- `TIME` columns weren't stored properly (bug in MySQL 3.22.0).
- `UPDATE` now returns information about how many rows were matched and updated, and how many ``warnings" occurred when doing the update.
- Fixed incorrect result from `FORMAT ( -100 , 2 )`.
- `ENUM` and `SET` columns were compared in binary (case-sensitive) fashion; changed to be case-insensitive.

## D.5.36. Changes in release 3.22.0 (18 May 1998: Alpha)

- New (backward-compatible) connect protocol that allows you to specify the database to use when connecting, to get much faster connections to a specific database.

The `mysql_real_connect ( )` call is changed to:

```
mysql_real_connect(MYSQL *mysql, const char *host, const char *user,
 const char *passwd, const char *db, uint port,
 const char *unix_socket, uint client_flag)
```

- Each connection is handled by its own thread, rather than by the master `accept ( )` thread. This fixes permanently the telnet bug that was a topic on the mail list some time ago.
- All TCP/IP connections are now checked with backward-resolution of the hostname to get better security. **mysqld** now has a local hostname resolver cache so connections should actually be faster than before, even with this feature.
- A site automatically is blocked from future connections if someone repeatedly connects with an ``improper header" (like when one uses telnet).
- You can now refer to tables in different databases with references of the form `tbl_name@db_name` or `db_name.tbl_name`. This makes it possible to give a user read access to some tables and write access to others simply by keeping them in different databases!
- Added `--user` option to **mysqld**, to allow it to run as another Unix user (if it is started as the Unix `root` user).
- Added caching of users and access rights (for faster access rights checking)
- Normal users (not anonymous ones) can change their password with **mysqladmin password "newpwd"**. This uses encrypted passwords that are not logged in the normal MySQL log!
- All important string functions are now coded in assembler for x86 Linux machines. This gives a speedup of 10% in many cases.
- For tables that have many columns, the column names are now hashed for much faster column name lookup (this speeds up some benchmark tests a lot!)
- Some benchmarks are changed to get better individual timing. (Some loops were so short that a specific test took < 2 seconds. The loops have been changed to take about 20 seconds to make it easier to compare different databases. A test that took 1-2 seconds before now takes 11-24 seconds, which is much better)
- Re-arranged `SELECT` code to handle some very specific queries involving group functions (like `COUNT ( * )`) without a `GROUP BY` but with `HAVING`. The following now works:

```
mysql> SELECT COUNT(*) as C FROM table HAVING C > 1;
```

- Changed the protocol for field functions to be faster and avoid some calls to `malloc()`.
- Added `-T32` option to **mysqld**, for running all queries under the main thread. This makes it possible to debug **mysqld** under Linux with **gdb**!
- Added optimization of `not_null_column IS NULL` (needed for some Access queries).
- Allow `STRAIGHT_JOIN` to be used between two tables to force the optimizer to join them in a specific order.
- String functions now return `VARCHAR` rather than `CHAR` and the column type is now `VARCHAR` for fields saved as `VARCHAR`. This should make the MyODBC driver better, but may break some old MySQL clients that don't handle `FIELD_TYPE_VARCHAR` the same way as `FIELD_TYPE_CHAR`.
- `CREATE INDEX` and `DROP INDEX` are now implemented through `ALTER TABLE. CREATE TABLE` is still the recommended (fast) way to create indexes.
- Added `--set-variable wait_timeout` to **mysqld**.
- Added time column to **mysqladmin processlist** to show how long a query has taken or how long a thread has slept.
- Added lots of new variables to show `variables` and some new to show `status`.
- Added new type `YEAR`. `YEAR` is stored in 1 byte with allowable values of 0, and 1901 to 2155.
- Added new `DATE` type that is stored in 3 bytes rather than 4 bytes. All new tables are created with the new date type if you don't use the `--old-protocol` option to **mysqld**.
- Fixed bug in record caches; for some queries, you could get `Error from table handler: #` on some operating systems.
- Added `--enable-asm` option to **configure**, for x86 machines (tested on Linux + `gcc`). This enables assembler functions for the most important string functions for more speed!

## D.6. Changes in release 3.21.x

MySQL 3.21 is quite old now, and should be avoided if possible. This information is kept here for historical purposes only.

### D.6.1. Changes in release 3.21.33 (08 Jul 1998)

- Fixed problem when sending `SIGHUP` to **mysqld**; **mysqld** dumped core when starting from boot on some systems.
- Fixed problem with losing a little memory for some connections.
- `DELETE FROM tbl_name` without a `WHERE` condition is now done the long way when you use `LOCK TABLES` or if the table is in use, to avoid race conditions.
- `INSERT INTO TABLE (timestamp_column) VALUES (NULL);` didn't set timestamp.

### D.6.2. Changes in release 3.21.32 (30 Jun 1998)

- Fixed some possible race conditions when doing many `reopen/close` on the same tables under

heavy load! This can happen if you execute **mysqladmin refresh** often. This could in some very rare cases corrupt the header of the index file and cause error 126 or 138.

- Fixed fatal bug in `refresh()` when running with the `--skip-external-locking` option. There was a "very small" time gap after a **mysqladmin refresh** when a table could be corrupted if one thread updated a table while another thread did **mysqladmin refresh** and another thread started a new update on the same table before the first thread had finished. A refresh (or `--flush-tables`) now does not return until all used tables are closed!
- `SELECT DISTINCT` with a `WHERE` clause that didn't match any rows returned a row in some contexts (bug only in 3.21.31).
- `GROUP BY + ORDER BY` returned one empty row when no rows were found.
- Fixed a bug in the range optimizer that wrote `Use_count: Wrong count for ...` in the error log file.

### D.6.3. Changes in release 3.21.31 (10 Jun 1998)

- Fixed a sign extension problem for the `TINYINT` type on Irix.
- Fixed problem with `LEFT("constant_string", function)`.
- Fixed problem with `FIND_IN_SET()`.
- `LEFT JOIN` dumped core if the second table is used with a constant `WHERE/ON` expression that uniquely identifies one record.
- Fixed problems with `DATE_FORMAT()` and incorrect dates. `DATE_FORMAT()` now ignores '%' to make it possible to extend it more easily in the future.

### D.6.4. Changes in release 3.21.30

- **mysql** now returns an exit code `> 0` if the query returned an error.
- Saving of command-line history to file in **mysql** client. By Tommy Larsen <tommy@mix.hive.no>.
- Fixed problem with empty lines that were ignored in `mysql.cc`.
- Save the pid of the signal handler thread in the pid file instead of the pid of the main thread.
- Added patch by <tommy@valley.ne.jp> to support Japanese characters SJIS and UJIS.
- Changed **safe\_mysql** to redirect startup messages to `host_name.err` instead of `host_name.log` to reclaim file space on **mysqladmin refresh**.
- `ENUM` always had the first entry as default value.
- `ALTER TABLE` wrote two entries to the update log.
- `sql_acc()` now closes the `mysql` grant tables after a reload to save table space and memory.
- Changed `LOAD DATA` to use less memory with tables and `BLOB` columns.
- Sorting on a function which made a division `/ 0` produced a wrong set in some cases.
- Fixed `SELECT` problem with `LEFT()` when using the `czech` character set.

- Fixed problem in **isamchk**; it couldn't repair a packed table in a very unusual case.
- SELECT statements with & or | (bit functions) failed on columns with NULL values.
- When comparing a field = field, where one of the fields was a part key, only the length of the part key was compared.

## D.6.5. Changes in release 3.21.29

- LOCK TABLES + DELETE from *tbl\_name* never removed locks properly.
- Fixed problem when grouping on an OR function.
- Fixed permission problem with umask( ) and creating new databases.
- Fixed permission problem on result file with SELECT ... INTO OUTFILE ...
- Fixed problem in range optimizer (core dump) for a very complex query.
- Fixed problem when using MIN(integer) or MAX(integer) in GROUP BY.
- Fixed bug on Alpha when using integer keys. (Other keys worked on Alpha.)
- Fixed bug in WEEK( "XXXX-xx-01" ).

## D.6.6. Changes in release 3.21.28

- Fixed socket permission (clients couldn't connect to Unix socket on Linux).
- Fixed bug in record caches; for some queries, you could get Error from table handler: # on some operating systems.

## D.6.7. Changes in release 3.21.27

- Added user level lock functions GET\_LOCK(string,timeout), RELEASE\_LOCK(string).
- Added Opened\_tables to show status.
- Changed connect timeout to 3 seconds to make it somewhat harder for crackers to kill **mysqld** through telnet + TCP/IP.
- Fixed bug in range optimizer when using WHERE *key\_part\_1* >= *something* AND *key\_part\_2* <= *something\_else*.
- Changed **configure** for detection of FreeBSD 3.0 9803xx and above
- WHERE with *string\_col\_key* = *constant\_string* didn't always find all rows if the column had many values differing only with characters of the same sort value (like e and e with an accent).
- Strings keys looked up with 'ref' were not compared in case-sensitive fashion.
- Added umask( ) to make log files non-readable for normal users.
- Ignore users with old (8-byte) password on startup if not using --old-protocol option to

**mysqld.**

- `SELECT` which matched all key fields returned the values in the case of the matched values, not of the found values. (Minor problem.)

## D.6.8. Changes in release 3.21.26

- `FROM_DAYS(0)` now returns "0000-00-00".
- In `DATE_FORMAT()`, PM and AM were swapped for hours 00 and 12.
- Extended the default maximum key size to 256.
- Fixed bug when using BLOB/TEXT in `GROUP BY` with many tables.
- An ENUM field that is not declared NOT NULL has NULL as the default value. (Previously, the default value was the first enumeration value.)
- Fixed bug in the join optimizer code when using many part keys on the same key: `INDEX(Organization, Surname(35), Initials(35))`.
- Added some tests to the table order optimizer to get some cases with `SELECT ... FROM many_tables` much faster.
- Added a retry loop around `accept()` to possibly fix some problems on some Linux machines.

## D.6.9. Changes in release 3.21.25

- Changed typedef 'string' to typedef 'my\_string' for better portability.
- You can now kill threads that are waiting on a disk-full condition.
- Fixed some problems with user-defined functions.
- Added long options to `isamchk`. Try `isamchk --help`.
- Fixed a bug when using 8 bytes long (alpha); `filesort()` didn't work. Affects `DISTINCT`, `ORDER BY` and `GROUP BY` on 64-bit processors.

## D.6.10. Changes in release 3.21.24

- Dynamic loadable functions. Based on source from Alexis Mikhailov.
- You couldn't delete from a table if no one had done a `SELECT` on the table.
- Fixed problem with range optimizer with many OR operators on key parts inside each other.
- Recoded `MIN()` and `MAX()` to work properly with strings and `HAVING`.
- Changed default umask value for new files from 0664 to 0660.
- Fixed problem with `LEFT JOIN` and constant expressions in the ON part.
- Added Italian error messages from <brenno@dewinter.com>.
- **configure** now works better on OSF/1 (tested on 4.0D).

- Added hooks to allow LIKE optimization with international character support.
- Upgraded DBI to 0.93.

## D.6.11. Changes in release 3.21.23

- The following symbols are now reserved words: TIME, DATE, TIMESTAMP, TEXT, BIT, ENUM, NO, ACTION, CHECK, YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, STATUS, VARIABLES.
- Setting a TIMESTAMP to NULL in LOAD DATA INFILE . . . didn't set the current time for the TIMESTAMP.
- Fix BETWEEN to recognize binary strings. Now BETWEEN is case-sensitive.
- Added --skip-thread-priority option to **mysqld**, for systems where **mysqld** thread scheduling doesn't work properly (BSDI 3.1).
- Added ODBC functions DAYNAME ( ) and MONTHNAME ( ).
- Added function TIME\_FORMAT ( ). This works like DATE\_FORMAT ( ), but takes a time string ( 'HH:MM:SS ' ) as argument.
- Fixed unlikely(?) key optimizer bug when using OR operators of key parts inside AND expressions.
- Added variables command to **mysqladmin**.
- A lot of small changes to the binary releases.
- Fixed a bug in the new protocol from MySQL 3.21.20.
- Changed ALTER TABLE to work with Windows (Windows can't rename open files). Also fixed a couple of small bugs in the Windows version.
- All standard MySQL clients are now ported to MySQL for Windows.
- MySQL can now be started as a service on NT.

## D.6.12. Changes in release 3.21.22

- Starting with this version, all MySQL distributions are configured, compiled and tested with crash-me and the benchmarks on the following platforms: SunOS 5.6 sun4u, SunOS 5.5.1 sun4u, SunOS 4.14 sun4c, SunOS 5.6 i86pc, Irix 6.3 mips5k, HP-UX 10.20 hppa, AIX 4.2.1 ppc, OSF/1 V4.0 alpha, FreeBSD 2.2.2 i86pc and BSDI 3.1 i386.
- Fix COUNT ( \* ) problems when the WHERE clause didn't match any records. (Bug from 3.21.17.)
- Removed that NULL = NULL is true. Now you must use IS NULL or IS NOT NULL to test whether a value is NULL. (This is according to standard SQL but may break old applications that are ported from mSQL.) You can get the old behavior by compiling with -DmSQL\_COMPLIANT.
- Fixed bug that caused core-dump when using many LEFT OUTER JOIN clauses.
- Fixed bug in ORDER BY on string formula with possible NULL values.
- Fixed problem in range optimizer when using <= on sub index.

- Added functions `DAYOFYEAR()`, `DAYOFMONTH()`, `MONTH()`, `YEAR()`, `WEEK()`, `QUARTER()`, `HOUR()`, `MINUTE()`, `SECOND()` and `FIND_IN_SET()`.
- Added `SHOW VARIABLES` command.
- Added support of "long constant strings" from standard SQL:  

```
mysql> SELECT 'first ' 'second'; -> 'first second'
```
- Upgraded `Mysql-Mysql-modules` to 1.1825.
- Upgraded `mysqlaccess` to 2.02.
- Fixed problem with Russian character set and `LIKE`.
- Ported to OpenBSD 2.1.
- New Dutch error messages.

### D.6.13. Changes in release 3.21.21a

- Configure changes for some operating systems.

### D.6.14. Changes in release 3.21.21

- Fixed optimizer bug when using `WHERE data_field = date_field2 AND date_field2 = constant`.
- Added `SHOW STATUS` command.
- Removed `manual.ps` from the source distribution to make it smaller.

### D.6.15. Changes in release 3.21.20

- Changed the maximum table name and column name lengths from 32 to 64.
- Aliases can now be of "any" length.
- Fixed `mysqladmin stat` to return the right number of queries.
- Changed protocol (downward compatible) to mark if a column has the `AUTO_INCREMENT` attribute or is a `TIMESTAMP`. This is needed for the new Java driver.
- Added Hebrew sorting order by Zeev Suraski.
- Solaris 2.6: Fixed `configure` bugs and increased maximum table size from 2GB to 4GB.

### D.6.16. Changes in release 3.21.19

- Upgraded `DBD` to 1.1823. This version implements `mysql_use_result` in `DBD-Mysql`.
- Benchmarks updated for `empress` (by Luuk).

- Fixed a case of slow range searching.
- Configure fixes (Docs directory).
- Added function `REVERSE ( )` (by Zeev Suraski).

## D.6.17. Changes in release 3.21.18

- Issue error message if client C functions are called in wrong order.
- Added automatic reconnect to the `libmysql.c` library. If a write command fails, an automatic reconnect is done.
- Small sort sets no longer use temporary files.
- Upgraded DBI to 0.91.
- Fixed a couple of problems with `LEFT OUTER JOIN`.
- Added `CROSS JOIN` syntax. `CROSS` is now a reserved word.
- Recoded **yacc/bison** stack allocation to be even safer and to allow MySQL to handle even bigger expressions.
- Fixed a couple of problems with the update log.
- `ORDER BY` was slow when used with key ranges.

## D.6.18. Changes in release 3.21.17

- Changed documentation string of `--with-unix-socket-path` to avoid confusion.
- Added ODBC and standard SQL style `LEFT OUTER JOIN`.
- The following are new reserved words: `LEFT`, `NATURAL`, `USING`.
- The client library now uses the value of the environment variable `MYSQL_HOST` as the default host if it's defined.
- `SELECT col_name, SUM(expr)` now returns `NULL` for `col_name` when there are matching rows.
- Fixed problem with comparing binary strings and `BLOB` values with ASCII characters over 127.
- Fixed lock problem: when freeing a read lock on a table with multiple read locks, a thread waiting for a write lock would have been given the lock. This shouldn't affect data integrity, but could possibly make **mysqld** restart if one thread was reading data that another thread modified.
- `LIMIT offset, count` didn't work in `INSERT ... SELECT`.
- Optimized key block caching. This is quicker than the old algorithm when using bigger key caches.

## D.6.19. Changes in release 3.21.16

- Added ODBC 2.0 & 3.0 functions `POWER ( )`, `SPACE ( )`, `COT ( )`, `DEGREES ( )`, `RADIANS ( )`,

`ROUND(2 arg)` and `TRUNCATE()`.

- **Warning: Incompatible change!** `LOCATE()` parameters were swapped according to ODBC standard. Fixed.
- Added function `TIME_TO_SEC()`.
- In some cases, default values were not used for `NOT NULL` fields.
- Timestamp wasn't always updated properly in `UPDATE SET ...` statements.
- Allow empty strings as default values for `BLOB` and `TEXT`, to be compatible with **mysqldump**.

## D.6.20. Changes in release 3.21.15

- **Warning: Incompatible change!** `mysqlperl` is now from `Msql-Mysql-modules`. This means that `connect()` now takes `host, database, user, password` arguments! The old version took `host, database, password, user`.
- Allow `DATE '1997-01-01'`, `TIME '12:10:10'` and `TIMESTAMP '1997-01-01 12:10:10'` formats required by standard SQL. **Warning: Incompatible change!** This has the unfortunate side effect that you no longer can have columns named `DATE`, `TIME` or `TIMESTAMP`. :( Old columns can still be accessed through `tbl_name.col_name!`)
- Changed Makefiles to hopefully work better with BSD systems. Also, `manual.dvi` is now included in the distribution to avoid having stupid **make** programs trying to rebuild it.
- `readline` library upgraded to version 2.1.
- A new sortorder `german-1`. That is a normal ISO-Latin1 with a german sort order.
- Perl DBI/DBD is now included in the distribution. DBI is now the recommended way to connect to MySQL from Perl.
- New portable benchmark suite with DBD, with test results from `mSQL 2.0.3`, `MySQL`, `PostgreSQL 6.2.1` and `Solid server 2.2`.
- `crash-me` is now included with the benchmarks; this is a Perl program designed to find as many limits as possible in an SQL server. Tested with `mSQL`, `PostgreSQL`, `Solid` and `MySQL`.
- Fixed bug in range-optimizer that crashed MySQL on some queries.
- Table and column name completion for **mysql** command-line tool, by Zeev Suraski and Andi Gutmans.
- Added new command `REPLACE` that works like `INSERT` but replaces conflicting records with the new record. `REPLACE INTO TABLE ... SELECT ...` works also.
- Added new commands `CREATE DATABASE db_name` and `DROP DATABASE db_name`.
- Added `RENAME` option to `ALTER TABLE`: `ALTER TABLE name RENAME TO new_name`.
- **make\_binary\_distribution** now includes `libgcc.a` in `libmysqlclient.a`. This should make linking work for people who don't have `gcc`.
- Changed `net_write()` to `my_net_write()` because of a name conflict with Sybase.
- • New function `DAYOFWEEK()` compatible with ODBC.
- Stack checking and **bison** memory overrun checking to make MySQL safer with weird queries.

## D.6.21. Changes in release 3.21.14b

- Fixed a couple of small **configure** problems on some platforms.

## D.6.22. Changes in release 3.21.14a

- Ported to SCO Openserver 5.0.4 with FSU Pthreads.
- HP-UX 10.20 should work.
- Added new function `DATE_FORMAT( )`.
- Added `NOT IN`.
- Added automatic removal of 'ODBC function conversions': {fn now( ) }
- Handle ODBC 2.50.3 option flags.
- Fixed comparison of `DATE` and `TIME` values with `NULL`.
- Changed language name from `germany` to `german` to be consistent with the other language names.
- Fixed sorting problem on functions returning a `FLOAT`. Previously, the values were converted to `INT` values before sorting.
- Fixed slow sorting when sorting on key field when using `key_col=constant`.
- Sorting on calculated `DOUBLE` values sorted on integer results instead.
- **mysql** no longer requires a database argument.
- Changed the place where `HAVING` should be. According to the SQL standards, it should be after `GROUP BY` but before `ORDER BY`. MySQL 3.20 incorrectly had it last.
- Added Sybase command `USE database` to start using another database.
- Added automatic adjusting of number of connections and table cache size if the maximum number of files that can be opened is less than needed. This should fix that **mysqld** doesn't crash even if you haven't done a **ulimit -n 256** before starting **mysqld**.
- Added lots of limit checks to make it safer when running with too little memory or when doing weird queries.

## D.6.23. Changes in release 3.21.13

- Added retry of interrupted reads and clearing of `errno`. This makes Linux systems much safer!
- Fixed locking bug when using many aliases on the same table in the same `SELECT`.
- Fixed bug with `LIKE` on number key.
- New error message so you can check whether the connection was lost while the command was running or whether the connection was down from the start.
- Added `--table` option to **mysql** to print in table format. Moved time and row information after query result. Added automatic reconnect of lost connections.

- Added `!=` as a synonym for `<>`.
- Added function `VERSION()` to make easier logs.
- New multi-user test `tests/fork_test.pl` to put some strain on the thread library.

## D.6.24. Changes in release 3.21.12

- Fixed `ftruncate()` call in MIT-pthreads. This made **isamchk** destroy the `.ISM` files on (Free)BSD 2.x systems.
- Fixed broken `__P_patch` in MIT-pthreads.
- Many memory overrun checks. All string functions now return `NULL` if the returned string should be longer than `max_allowed_packet` bytes.
- Changed the name of the `INTERVAL` type to `ENUM`, because `INTERVAL` is used in standard SQL.
- In some cases, doing a `JOIN + GROUP + INTO OUTFILE`, the result wasn't grouped.
- `LIKE` with `'_'` as last character didn't work. Fixed.
- Added extended standard SQL `TRIM()` function.
- Added `CURTIME()`.
- Added `ENCRYPT()` function by Zeev Suraski.
- Fixed better `FOREIGN KEY` syntax skipping. New reserved words: `MATCH`, `FULL`, `PARTIAL`.
- **mysqld** now allows IP number and hostname for the `--bind-address` option.
- Added `SET CHARACTER SET cp1251_koi8` to enable conversions of data to and from the `cp1251_koi8` character set.
- Lots of changes for Windows 95 port. In theory, this version should now be easily portable to Windows 95.
- Changed the `CREATE COLUMN` syntax of `NOT NULL` columns to be after the `DEFAULT` value, as specified in the SQL standard. This makes **mysqldump** with `NOT NULL` and default values incompatible with MySQL 3.20.
- Added many function name aliases so the functions can be used with ODBC or standard SQL syntax.
- Fixed syntax of `ALTER TABLE tbl_name ALTER COLUMN col_name SET DEFAULT NULL`.
- Added `CHAR` and `BIT` as synonyms for `CHAR(1)`.
- Fixed core dump when updating as a user who has only `SELECT` privilege.
- `INSERT ... SELECT ... GROUP BY` didn't work in some cases. An `Invalid use of group function` error occurred.
- When using `LIMIT`, `SELECT` now always uses keys instead of record scan. This gives better performance on `SELECT` and a `WHERE` that matches many rows.
- Added Russian error messages.

## D.6.25. Changes in release 3.21.11

- Configure changes.
- MySQL now works with the new thread library on BSD/OS 3.0.
- Added new group functions `BIT_OR()` and `BIT_AND()`.
- Added compatibility functions `CHECK` and `REFERENCES`. `CHECK` is now a reserved word.
- Added `ALL` option to `GRANT` for better compatibility. (`GRANT` is still a dummy function.)
- Added partly translated Dutch error messages.
- Fixed bug in `ORDER BY` and `GROUP BY` with `NULL` columns.
- Added function `LAST_INSERT_ID()` SQL function to retrieve last `AUTO_INCREMENT` value. This is intended for clients to ODBC that can't use the `mysql_insert_id()` API function, but can be used by any client.
- Added `--flush-logs` option to **mysqldadmin**.
- Added command `STATUS` to **mysql**.
- Fixed problem with `ORDER BY/GROUP BY` because of bug in **gcc**.
- Fixed problem with `INSERT ... SELECT ... GROUP BY`.

## D.6.26. Changes in release 3.21.10

- New program **mysqlaccess**.
- `CREATE` now supports all ODBC types and the `mSQL TEXT` type. All ODBC 2.5 functions are also supported (added `REPEAT`). This provides better portability.
- Added text types `TINYTEXT`, `TEXT`, `MEDIUMTEXT` and `LONGTEXT`. These are actually `BLOB` types, but all searching is done in case-insensitive fashion.
- All old `BLOB` fields are now `TEXT` fields. This only changes that all searching on strings is done in case-sensitive fashion. You must do an `ALTER TABLE` and change the data type to `BLOB` if you want to have tests done in case-sensitive fashion.
- Fixed some **configure** issues.
- Made the locking code a bit safer. Fixed very unlikely deadlock situation.
- Fixed a couple of bugs in the range optimizer. Now the new range benchmark `test-select` works.

## D.6.27. Changes in release 3.21.9

- Added `--enable-unix-socket=pathname` option to **configure**.
- Fixed a couple of portability problems with include files.
- Fixed bug in range calculation that could return empty set when searching on multiple key with only one entry (very rare).

- Most things ported to FSU Pthreads, which should allow MySQL to run on SCO. See Section 2.12.5.8, “SCO Notes”.

## D.6.28. Changes in release 3.21.8

- Works now in Solaris 2.6.
- Added handling of calculation of SUM() functions. For example, you can now use SUM(column)/COUNT(column).
- Added handling of trigometric functions: PI(), ACOS(), ASIN(), ATAN(), COS(), SIN() and TAN().
- New languages: Norwegian, Norwegian-ny and Portuguese.
- Fixed parameter bug in net\_print() in procedure.cc.
- Fixed a couple of memory leaks.
- Now allow also the old SELECT ... INTO OUTFILE syntax.
- Fixed bug with GROUP BY and SELECT on key with many values.
- mysql\_fetch\_lengths() sometimes returned incorrect lengths when you used mysql\_use\_result(). This affected at least some cases of **mysqldump --quick**.
- Fixed bug in optimization of WHERE const op field.
- Fixed problem when sorting on NULL fields.
- Fixed a couple of 64-bit (Alpha) problems.
- Added --pid-file=# option to **mysqld**.
- Added date formatting to FROM\_UNIXTIME(), originally by Zeev Suraski.
- Fixed bug in BETWEEN in range optimizer (did only test = of the first argument).
- Added machine-dependent files for MIT-pthreads i386-SCO. There is probably more to do to get this to work on SCO 3.5.

## D.6.29. Changes in release 3.21.7

- Changed Makefile.am to take advantage of Automake 1.2.
- Added the beginnings of a benchmark suite.
- Added more secure password handling.
- Added new client function mysql\_errno(), to get the error number of the error message. This makes error checking in the client much easier. This makes the new server incompatible with the 3.20.x server when running without --old-protocol. The client code is backward-compatible. More information can be found in the README file!
- Fixed some problems when using very long, illegal names.

## D.6.30. Changes in release 3.21.6

- Fixed more portability issues (incorrect `sigwait` and `sigset` defines).
- **configure** should now be able to detect the last argument to `accept()`.

## D.6.31. Changes in release 3.21.5

- Should now work with FreeBSD 3.0 if used with `FreeBSD-3.0-libc_r-1.0.diff`, which can be found at <http://dev.mysql.com/downloads/os-freebsd.html>.
- Added new `-O tmp_table_size=#` option to **mysqld**.
- New function `FROM_UNIXTIME(timestamp)` which returns a date string in `'YYYY-MM-DD HH:MM:SS'` format.
- New function `SEC_TO_TIME(seconds)` which returns a string in `'HH:MM:SS'` format.
- New function `SUBSTRING_INDEX()`, originally by Zeev Suraski.

## D.6.32. Changes in release 3.21.4

- Should now configure and compile on OSF/1 4.0 with the DEC compiler.
- Configuration and compilation on BSD/OS 3.0 works, but due to some bugs in BSD/OS 3.0, **mysqld** doesn't work on it yet.
- Configuration and compilation on FreeBSD 3.0 works, but I couldn't get `pthread_create` to work.

## D.6.33. Changes in release 3.21.3

- Added reverse check lookup of hostnames to get better security.
- Fixed some possible buffer overflows if filenames that are too long are used.
- **mysqld** doesn't accept hostnames that start with digits followed by a `'.'`, because the hostname may look like an IP number.
- Added `--skip-networking` option to **mysqld**, to allow only socket connections. (This does not work with MIT-pthreads!)
- Added check of too long table names for alias.
- Added check whether database name is okay.
- Added check whether too long table names.
- Removed incorrect `free()` that killed the server on `CREATE DATABASE` or `DROP DATABASE`.
- Changed some **mysqld** `-O` options to better names.
- Added `-O join_cache_size=#` option to **mysqld**.
- Added `-O max_join_size=#` option to **mysqld**, to be able to set a limit how big queries (in this case `big = slow`) one should be able to handle without specifying `SET SQL_BIG_SELECTS=1`. A `#` is about 10 examined records. The default is ```unlimited```.

- When comparing a `TIME`, `DATE`, `DATETIME` or `TIMESTAMP` column to a constant, the constant is converted to a time value before performing the comparison. This makes it easier to get ODBC (particularly Access97) to work with these types. It should also make dates easier to use and the comparisons should be quicker than before.
- Applied patch from Jochen Wiedmann that allows `query()` in `mysqlperl` to take a query with `\0` in it.
- Storing a timestamp with a two-digit year (`YYMMDD`) didn't work.
- Fix that timestamp wasn't automatically updated if set in an `UPDATE` clause.
- Now the automatic timestamp field is the `FIRST` timestamp field.
- `SELECT * INTO OUTFILE`, which didn't correctly if the outfile existed.
- **mysql** now shows the thread ID when starting or doing a reconnect.
- Changed the default sort buffer size from 2MB to 1MB.

## D.6.34. Changes in release 3.21.2

- The range optimizer is coded, but only 85% tested. It can be enabled with `--new`, but it crashes core a lot yet...
- More portable. Should compile on AIX and alpha-digital. At least the `isam` library should be relatively 64-bit clean.
- New **isamchk** which can detect and fix more problems.
- New options for `isamlog`.
- Using new version of Automake.
- Many small portability changes (from the AIX and alpha-digital port) Better checking of `pthread(s)` library.
- czech error messages by <snajdr@pvt.net>.
- Decreased size of some buffers to get fewer problems on systems with little memory. Also added more checks to handle "out of memory" problems.
- **mysqladmin**: you can now do **mysqladmin kill 5,6,7,8** to kill multiple threads.
- When the maximum connection limit is reached, one extra connection by a user with the **process\_acl** privilege is granted.
- Added `-O backlog=#` option to **mysqld**.
- Increased maximum packet size from 512KB to 1024KB for client.
- Almost all of the function code is now tested in the internal test suite.
- `ALTER TABLE` now returns warnings from field conversions.
- Port changed to 3306 (got it reserved from ISI).
- Added a fix for Visual FoxBase so that any schema name from a table specification is automatically removed.
- New function `ASCII()`.

- Removed function `BETWEEN(a,b,c)`. Use the standard SQL syntax instead: `expr BETWEEN expr AND expr`.
- MySQL no longer has to use an extra temporary table when sorting on functions or `SUM()` functions.
- Fixed bug that you couldn't use `tbl_name.field_name` in `UPDATE`.
- Fixed `SELECT DISTINCT` when using 'hidden group'. For example:
 

```
mysql> SELECT DISTINCT MOD(some_field,10) FROM test
-> GROUP BY some_field;
```

Note: `some_field` is normally in the `SELECT` part. Standard SQL should require it.

## D.6.35. Changes in release 3.21.0

- New reserved words used: `INTERVAL`, `EXPLAIN`, `READ`, `WRITE`, `BINARY`.
- Added ODBC function `CHAR(num, ...)`.
- New operator `IN`. This uses a binary search to find a match.
- New command `LOCK TABLES tbl_name [AS alias] {READ|WRITE} ...`
- Added `--log-update` option to **mysqld**, to get a log suitable for incremental updates.
- New command `EXPLAIN SELECT ...` to get information about how the optimizer does the join.
- For easier client code, the client should no longer use `FIELD_TYPE_TINY_BLOB`, `FIELD_TYPE_MEDIUM_BLOB`, `FIELD_TYPE_LONG_BLOB` or `FIELD_TYPE_VAR_STRING` (as previously returned by `mysql_list_fields`). You should instead use only `FIELD_TYPE_BLOB` or `FIELD_TYPE_STRING`. If you want exact types, you should use the command `SHOW FIELDS`.
- Added varbinary syntax: `0x#####` which can be used as a string (default) or a number.
- `FIELD_TYPE_CHAR` is renamed to `FIELD_TYPE_TINY`.
- Changed all fields to C++ classes.
- Removed `FORM` struct.
- Fields with `DEFAULT` values no longer need to be `NOT NULL`.
- New field types:
  - `ENUM`

A string which can take only a couple of defined values. The value is stored as a 1-3 byte number that is mapped automatically to a string. This is sorted according to string positions!
  - `SET`

A string which may have one or many string values separated by ','. The string is stored as a 1-, 2-, 3-, 4- or 8-byte number where each bit stands for a specific set member. This is sorted according to the unsigned value of the stored packed number.
- Now all function calculation is done with `double` or `long long`. This provides the full 64-bit range with bit functions and fixes some conversions that previously could result in precision losses. One should avoid using `unsigned long long` columns with full 64-bit range

(numbers bigger than 9223372036854775807) because calculations are done with signed long long.

- ORDER BY now puts NULL field values first. GROUP BY also works with NULL values.
- Full WHERE with expressions.
- New range optimizer that can resolve ranges when some keypart prefix is constant. Example:

```
mysql> SELECT * FROM tbl_name
-> WHERE key_part_1='customer'
-> AND key_part_2>=10 AND key_part_2<=10;
```

## D.7. Changes in release 3.20.x

MySQL 3.20 is quite old now, and should be avoided if possible. This information is kept here for historical purposes only.

Changes from 3.20.18 to 3.20.32b are not documented here because the 3.21 release branched here. And the relevant changes are also documented as changes to the 3.21 version.

### D.7.1. Changes in release 3.20.18

- Added `-p#` (remove # directories from path) to `isamlog`. All files are written with a relative path from the database directory. Now **mysqld** shouldn't crash on shutdown when using the `-log-isam` option.
- New `mysqlperl` version. It is now compatible with `mysqlperl-0.63`.
- New DBD module available.
- Added group function `STD( )` (standard deviation).
- The **mysqld** server is now compiled by default without debugging information. This makes the daemon smaller and faster.
- Now one usually only has to specify the `--basedir` option to **mysqld**. All other paths are relative in a normal installation.
- BLOB columns sometimes contained garbage when used with a `SELECT` on more than one table and `ORDER BY`.
- Fixed that calculations that are not in `GROUP BY` work as expected (standard SQL extension). Example:  

```
mysql> SELECT id,id+1 FROM table GROUP BY id;
```
- The test of using `MYSQL_PWD` was reversed. Now `MYSQL_PWD` is enabled as default in the default release.
- Fixed conversion bug which caused **mysqld** to core dump with Arithmetic error on SPARC-386.
- Added `--unbuffered` option to **mysql**, for new **mysqlaccess**.
- When using overlapping (unnecessary) keys and join over many tables, the optimizer could get confused and return 0 records.

## D.7.2. Changes in release 3.20.17

- You can now use BLOB columns and the functions `IS NULL` and `IS NOT NULL` in the `WHERE` clause.
- All communication packets and row buffers are now allocated dynamically on demand. The default value of `max_allowed_packet` is now 64KB for the server and 512KB for the client. This is mainly used to catch incorrect packets that could trash all memory. The server limit may be changed when it is started.
- Changed stack usage to use less memory.
- Changed **safe\_mysqld** to check for running daemon.
- The `ELT()` function is renamed to `FIELD()`. The new `ELT()` function returns a value based on an index: `FIELD()` is the inverse of `ELT()` Example: `ELT(2, "A", "B", "C")` returns "B". `FIELD("B", "A", "B", "C")` returns 2.
- `COUNT(field)`, where `field` could have a `NULL` value, now works.
- A couple of bugs fixed in `SELECT ... GROUP BY`.
- Fixed memory overrun bug in `WHERE` with many unoptimizable brace levels.
- Fixed some small bugs in the grant code.
- If hostname isn't found by `get_hostname`, only the IP is checked. Previously, you got `Access denied`.
- Inserts of timestamps with values didn't always work.
- `INSERT INTO ... SELECT ... WHERE` could give the error `Duplicated field`.
- Added some tests to **safe\_mysqld** to make it ``safer."
- `LIKE` was case-sensitive in some places and case-insensitive in others. Now `LIKE` is always case-insensitive.
- `mysql.cc`: Allow '#' anywhere on the line.
- New command `SET SQL_SELECT_LIMIT=#`. See the FAQ for more details.
- New version of the **mysqlaccess** script.
- Change `FROM_DAYS()` and `WEEKDAY()` to also take a full `TIMESTAMP` or `DATETIME` as argument. Before they only took a number of type `YYYYMMDD` or `YYMMDD`.
- Added new function `UNIX_TIMESTAMP(timestamp_column)`.

## D.7.3. Changes in release 3.20.16

- More changes in MIT-pthreads to get them safer. Fixed also some link bugs at least in SunOS.
- Changed **mysqld** to work around a bug in MIT-pthreads. This makes multiple small `SELECT` operations 20 times faster. Now `lock_test.pl` should work.
- Added `mysql_FetchHash(handle)` to `mysqlperl`.
- The **mysqlbug** script is now distributed built to allow for reporting bugs that appear during the build with it.

- Changed `libmysql.c` to prefer `getpwuid()` instead of `cuserid()`.
- Fixed bug in `SELECT` optimizer when using many tables with the same column used as key to different tables.
- Added new `latin2` and Russian `KOI8` character tables.
- Added support for a dummy `GRANT` command to satisfy Powerbuilder.

## D.7.4. Changes in release 3.20.15

- Fixed fatal bug `packets out of order` when using MIT-pthreads.
- Removed possible loop when a thread waits for command from client and `fcntl()` fails. Thanks to Mike Bretz for finding this bug.
- Changed alarm loop in `mysqld.cc` because shutdown didn't always succeed in Linux.
- Removed use of `termbits` from `mysql.cc`. This conflicted with `glibc 2.0`.
- Fixed some syntax errors for at least BSD and Linux.
- Fixed bug when doing a `SELECT` as superuser without a database.
- Fixed bug when doing `SELECT` with group calculation to outfile.

## D.7.5. Changes in release 3.20.14

- If one gives `-p` or `--password` option to **mysql** without an argument, the user is solicited for the password from the tty.
- Added default password from `MYSQL_PWD` (by Elmar Haneke).
- Added command `kill` to **mysqladmin** to kill a specific MySQL thread.
- Sometimes when doing a reconnect on a down connection this succeeded first on second try.
- Fixed adding an `AUTO_INCREMENT` key with `ALTER_TABLE`.
- `AVG()` gave too small value on some `SELECT` statements with `GROUP BY` and `ORDER BY`.
- Added new `DATETIME` type (by Giovanni Maruzzelli <maruzz@matrice.it>).
- Fixed that defining `DONT_USE_DEFAULT_FIELDS` works.
- Changed to use a thread to handle alarms instead of signals on Solaris to avoid race conditions.
- Fixed default length of signed numbers. (George Harvey <georgeh@pinac1.co.uk>.)
- Allow anything for `CREATE INDEX`.
- Add prezeros when packing numbers to `DATE`, `TIME` and `TIMESTAMP`.
- Fixed a bug in `OR` of multiple tables (gave empty set).
- Added many patches to MIT-pthreads. This fixes at least one lookup bug.

## D.7.6. Changes in release 3.20.13

- Added standard SQL DATE and TIME types.
- Fixed bug in SELECT with AND-OR levels.
- Added support for Slovenian characters. The Contrib directory contains source and instructions for adding other character sets.
- Fixed bug with LIMIT and ORDER BY.
- Allow ORDER BY and GROUP BY on items that aren't in the SELECT list. (Thanks to Wim Bonis <bonis@kiss.de>, for pointing this out.)
- Allow setting of timestamp values in INSERT.
- Fixed bug with SELECT ... WHERE ... = NULL.
- Added changes for glibc 2.0. To get glibc to work, you should add the glibc-2.0-sigwait-patch before compiling glibc.
- Fixed bug in ALTER TABLE when changing a NOT NULL field to allow NULL values.
- Added some standard SQL synonyms as field types to CREATE TABLE. CREATE TABLE now allows FLOAT(4) and FLOAT(8) to mean FLOAT and DOUBLE.
- New utility program **mysqlaccess** by <Yves.Carlier@rug.ac.be>. This program shows the access rights for a specific user and the grant rows that determine this grant.
- Added WHERE const op field (by <bonis@kiss.de>).

## D.7.7. Changes in release 3.20.11

- When using SELECT ... INTO outfile, all temporary tables are ISAM instead of HEAP to allow big dumps.
- Changed date functions to be string functions. This fixed some "funny" side effects when sorting on dates.
- Extended ALTER TABLE for standard SQL compliance.
- Some minor compatibility changes.
- Added --port and --socket options to all utility programs and **mysqld**.
- Fixed MIT-pthreads readdir\_r(). Now **mysqladmin create database** and **mysqladmin drop database** should work.
- Changed MIT-pthreads to use our tempnam(). This should fix the "sort aborted" bug.
- Added sync of records count in sql\_update. This fixed slow updates on first connection. (Thanks to Vaclav Bittner for the test.)

## D.7.8. Changes in release 3.20.10

- New insert type: INSERT INTO ... SELECT ...
- MEDIUMBLOB fixed.
- Fixed bug in ALTER TABLE and BLOB values.

- `SELECT ... INTO OUTFILE` now creates the file in the current database directory.
- `DROP TABLE` now can take a list of tables.
- Oracle synonym `DESCRIBE (DESC)`.
- Changes to **make\_binary\_distribution**.
- Added some comments to installation instructions about **configure** C++ link test.
- Added `--without-perl` option to **configure**.
- Lots of small portability changes.

## D.7.9. Changes in release 3.20.9

- `ALTER TABLE` didn't copy null bit. As a result, fields that were allowed to have NULL values were always NULL.
- `CREATE` didn't take numbers as `DEFAULT`.
- Some compatibility changes for SunOS.
- Removed `config.cache` from old distribution.

## D.7.10. Changes in release 3.20.8

- Fixed bug with `ALTER TABLE` and multiple-part keys.

## D.7.11. Changes in release 3.20.7

- New commands: `ALTER TABLE`, `SELECT ... INTO OUTFILE` and `LOAD DATA INFILE`.
- New function: `NOW()`.
- Added new field `File_priv` to `mysql/user` table.
- New script `add_file_priv` which adds the new field `File_priv` to the `user` table. This script must be executed if you want to use the new `SELECT ... INTO` and `LOAD DATA INFILE ...` commands with a version of MySQL earlier than 3.20.7.
- Fixed bug in locking code, which made `lock_test.pl` test fail.
- New files `NEW` and `BUGS`.
- Changed `select_test.c` and `insert_test.c` to include `config.h`.
- Added `status` command to **mysqladmin** for short logging.
- Increased maximum number of keys to 16 and maximum number of key parts to 15.
- Use of sub keys. A key may now be a prefix of a string field.
- Added `-k` option to **mysqlshow**, to get key information for a table.
- Added long options to **mysqldump**.

## D.7.12. Changes in release 3.20.6

- Portable to more systems because of MIT-pthreads, which is used automatically if **configure** cannot find a `-lpthreads` library.
- Added GNU-style long options to almost all programs. Test with `program --help`.
- Some shared library support for Linux.
- The FAQ is now in `.texi` format and is available in `.html`, `.txt` and `.ps` formats.
- Added new SQL function `RAND([init])`.
- Changed `sql_lex` to handle `\0` unquoted, but the client can't send the query through the C API, because it takes a `str` pointer. You must use `mysql_real_query()` to send the query.
- Added API function `mysql_get_client_info()`.
- **mysqld** now uses the `N_MAX_KEY_LENGTH` from `nisam.h` as the maximum allowable key length.
- The following now works:

```
mysql> SELECT filter_nr,filter_nr FROM filter ORDER BY filter_nr;
```

Previously, this resulted in the error: Column: 'filter\_nr' in order clause is ambiguous.

- **mysql** now outputs `'\0'`, `'\t'`, `'\n'` and `'\\'` when encountering ASCII 0, tab, newline, or `'\'` while writing tab-separated output. This is to allow printing of binary data in a portable format. To get the old behavior, use `-r` (or `--raw`).
- Added german error messages (60 of 80 error messages translated).
- Added new API function `mysql_fetch_lengths(MYSQL_RES *)`, which returns an array of column lengths (of type `uint`).
- Fixed bug with `IS NULL` in `WHERE` clause.
- Changed the optimizer a little to get better results when searching on a key part.
- Added `SELECT` option `STRAIGHT_JOIN` to tell the optimizer that it should join tables in the given order.
- Added support for comments starting with `'--'` in `mysql.cc` (Postgres syntax).
- You can have `SELECT` expressions and table columns in a `SELECT` which are not used in the group part. This makes it efficient to implement lookups. The column that is used should be a constant for each group because the value is calculated only once for the first row that is found for a group.

```
mysql> SELECT id,lookup.text,SUM(*) FROM test,lookup
-> WHERE test.id=lookup.id GROUP BY id;
```

- Fixed bug in `SUM(function)` (could cause a core dump).
- Changed `AUTO_INCREMENT` placement in the SQL query:  

```
INSERT INTO table (auto_field) VALUES (0);
```

inserted 0, but it should insert an `AUTO_INCREMENT` value.
- `mysqlshow.c`: Added number of records in table. Had to change the client code a little to fix

this.

- **mysql** now allows doubled ' ' or " " within strings for embedded ' or " .
- New math functions: `EXP()`, `LOG()`, `SQRT()`, `ROUND()`, `CEILING()` .

## D.7.13. Changes in release 3.20.3

- The **configure** source now compiles a thread-free client library `-lmysqlclient`. This is the only library that needs to be linked with client applications. When using the binary releases, you must link with `-lmysql -lmysys -ldbbug -lmystrings` as before.
- New `readline` library from `bash-2.0`.
- LOTS of small changes to **configure** and `makefiles` (and related source).
- It should now be possible to compile in another directory using `VPATH`. Tested with GNU Make 3.75.
- **safe\_mysql** and **mysql.server** changed to be more compatible between the source and the binary releases.
- `LIMIT` now takes one or two numeric arguments. If one argument is given, it indicates the maximum number of rows in a result. If two arguments are given, the first argument indicates the offset of the first row to return, the second is the maximum number of rows. With this it's easy to do a poor man's next page/previous page WWW application.
- Changed name of SQL function `FIELDS()` to `ELT()`. Changed SQL function `INTERVALL()` to `INTERVAL()`.
- Made `SHOW COLUMNS` a synonym for `SHOW FIELDS`. Added compatibility syntax `FRIEND KEY` to `CREATE TABLE`. In MySQL, this creates a non-unique key on the given columns.
- Added `CREATE INDEX` and `DROP INDEX` as compatibility functions. In MySQL, `CREATE INDEX` only checks whether the index exists and issues an error if it doesn't exist. `DROP INDEX` always succeeds.
- `mysqladmin.c`: added client version to version information.
- Fixed core dump bug in `sql_acl` (core on new connection).
- Removed `host`, `user` and `db` tables from database `test` in the distribution.
- `FIELD_TYPE_CHAR` can now be signed (-128 to 127) or unsigned (0 to 255) Previously, it was always unsigned.
- Bug fixes in `CONCAT()` and `WEEKDAY()`.
- Changed a lot of source to get **mysqld** to be compiled with SunPro compiler.
- SQL functions must now have a ' (' immediately after the function name (no intervening space). For example, `'USER('` is regarded as beginning a function call, and `'USER ('` is regarded as an identifier `USER` followed by a ' (' , not as a function call.

## D.7.14. Changes in release 3.20.0

- The source distribution is done with **configure** and Automake. It makes porting much easier. The `readline` library is included in the distribution.

- Separate client compilation: the client code should be very easy to compile on systems which don't have threads.
- The old Perl interface code is automatically compiled and installed. Automatic compiling of DBD follows when the new DBD code is ported.
- Dynamic language support: **mysqld** can now be started with Swedish or English (default) error messages.
- New functions: `INSERT()`, `RTRIM()`, `LTRIM()` and `FORMAT()`.
- **mysqldump** now works correctly for all field types (even `AUTO_INCREMENT`). The format for `SHOW FIELDS FROM tbl_name` is changed so the `Type` column contains information suitable for `CREATE TABLE`. In previous releases, some `CREATE TABLE` information had to be patched when re-creating tables.
- Some parser bugs from 3.19.5 (`BLOB` and `TIMESTAMP`) are corrected. `TIMESTAMP` now returns different date information depending on its create length.
- Changed parser to allow a database, table or field name to start with a number or `'_'`.
- All old C code from Unireg changed to C++ and cleaned up. This makes the daemon a little smaller and easier to understand.
- A lot of small bugfixes done.
- New `INSTALL` files (not final version) and some information regarding porting.

## D.8. Changes in release 3.19.x

MySQL 3.19 is quite old now, and should be avoided if possible. This information is kept here for historical purposes only.

### D.8.1. Changes in release 3.19.5

- Some new functions, some more optimization on joins.
- Should now compile clean on Linux (2.0.x).
- Added functions `DATABASE()`, `USER()`, `POW()`, `LOG10()` (needed for ODBC).
- In a `WHERE` with an `ORDER BY` on fields from only one table, the table is now preferred as first table in a multi-join.
- `HAVING` and `IS NULL` or `IS NOT NULL` now works.
- A group on one column and a sort on a group function (`SUM()`, `AVG()`...) didn't work together. Fixed.
- **mysqldump**: Didn't send password to server.

### D.8.2. Changes in release 3.19.4

- Fixed horrible locking bug when inserting in one thread and reading in another thread.
- Fixed one-off decimal bug. 1.00 was output as 1.0.
- Added attribute `'Locked'` to process list as information if a query is locked by another query.

- Fixed full magic timestamp. Timestamp length may now be 14, 12, 10, 8, 6, 4 or 2 bytes.
- Sort on some numeric functions could sort incorrectly on last number.
- `IF(arg, syntax_error, syntax_error)` crashed.
- Added functions `CEILING()`, `ROUND()`, `EXP()`, `LOG()` and `SQRT()`.
- Enhanced `BETWEEN` to handle strings.

### D.8.3. Changes in release 3.19.3

- Fixed `SELECT` with grouping on BLOB columns not to return incorrect BLOB info. Grouping, sorting and distinct on BLOB columns does not yet work as expected (probably it groups/sorts by the first 7 characters in the BLOB). Grouping on formulas with a fixed string size (use `MID()` on a BLOB) should work.
- When doing a full join (no direct keys) on multiple tables with BLOB fields, the BLOB was garbage on output.
- Fixed `DISTINCT` with calculated columns.

## D.9. InnoDB Change History

Starting from 4.0.22 and 4.1.5, all InnoDB changes are included in the MySQL Change History, and this manual section is no longer separately maintained.

### D.9.1. MySQL/InnoDB-4.0.21, September 10, 2004

Functionality added or changed:

- Renamed the `innodb.status.<pid>` files (created in the data directory) to `innodb_status.<pid>`. This avoids problems on filesystems that do not allow multiple periods in filenames.
- Added `innodb_status_file` system variable to **mysqld** to control whether output from `SHOW INNODB STATUS` is written to a `innodb_status.<pid>` file in the data directory. By default, the file is not created. To create it, start **mysqld** with the `-innodb_status_file=1` option.
- Changes for NetWare to exit InnoDB gracefully on NetWare even in a case of an assertion failure, instead of intentionally crashing the `'mysqld'` server process.

Bugs fixed:

- Fixed a bug in `ON DELETE CASCADE` and `ON UPDATE CASCADE` foreign key constraints: long chains of cascaded operations would cause a stack overflow and crash the server. Cascaded operations are now limited to 15 levels. (Bug #4446 [<http://bugs.mysql.com/4446>])
- Fixed a possible bug in `LOCK TABLES` introduced in MySQL/InnoDB-4.0.19: The count of tables explicitly locked by a transaction was incremented only after the locks were granted, but decremented when the lock structures were destroyed.
- Fixed a bug in `UNLOCK TABLES` in `AUTOCOMMIT=0` mode, introduced in MySQL/InnoDB-4.0.19: The memory allocated for some locks acquired by the transaction could be deallocated before those locks were released. The bug can lead to crashes and memory corruption of

the buffer pool when the transaction acquires a large number of locks (table locks or row-level locks).

- Increment the InnoDB watchdog timeout during `CHECK TABLE`. A long-running `CHECK TABLE` would cause InnoDB to complain about a 'long semaphore wait', and crash the server, if a query had to wait more than 600 seconds behind that `CHECK TABLE` operation. (Bug #2694 [<http://bugs.mysql.com/2694>])
- If you configure `innodb_additional_mem_pool_size` so small that InnoDB memory allocation spills over from it, then every 4 billionth spill may cause memory corruption. A symptom is a printout like below in the `.err` log. The workaround is to make `innodb_additional_mem_pool_size` big enough to hold all memory allocation. Use `SHOW INNODB STATUS` to determine that there is plenty of free space available in the additional mem pool, and the total allocated memory stays rather constant.

```
InnoDB: Error: Mem area size is 0. Possibly a memory overrun of the
InnoDB: previous allocated area!
InnoDB: Apparent memory corruption: mem dump len 500; hex
```

- The special meaning of the table names `innodb_monitor`, `innodb_lock_monitor`, `innodb_tablespace_monitor`, `innodb_table_monitor`, and `innodb_validate` in `CREATE TABLE` and `DROP TABLE` statements was accidentally removed in MySQL/InnoDB-4.0.19. The diagnostic functions attached to these special table names (see Section 15.12.1, “`SHOW INNODB STATUS` and the InnoDB Monitors”) are accessible again in MySQL/InnoDB-4.0.21.
- When the private SQL parser of InnoDB was modified in MySQL/InnoDB-4.0.19 in order to allow the use of the apostrophe (') in table and column names, the fix relied on a previously unused function `mem_realloc()`, whose implementation was incorrect. As a result, InnoDB can incorrectly parse column and table names as the empty string. The InnoDB `realloc()` implementation has been corrected in MySQL/InnoDB-4.0.21.
- Fixed a glitch introduced in 4.0.18 and 4.1.2: in `SHOW TABLE STATUS` InnoDB systematically overestimated the row count by 1 if the table fit on a single 16 kB data page.
- InnoDB created temporary files with the C library function `tmpfile()`. On Windows, the files would be created in the root directory of the current file system. To correct this behavior, the invocations of `tmpfile()` were replaced with code that uses the function `create_temp_file()` in the MySQL portability layer. (Bug #3998 [<http://bugs.mysql.com/3998>])
- If `ALTER TABLE ... DROP FOREIGN KEY ...` fails because of a wrong constraint name, return a table handler error number 150 instead of 152.
- If there was little file I/O in InnoDB, but the insert buffer was used, it could happen that 'Pending normal aio reads' was bigger than 0, but the I/O handler thread did not get waken up in 600 seconds. This resulted in a hang, and crashing of InnoDB.
- If we `RENAMED` a table, InnoDB forgot to load the `FOREIGN KEY` constraints that reference the new table name, and forgot to check that they are compatible with the table.

## D.9.2. MySQL/InnoDB-4.1.4, August 31, 2004

Functionality added or changed:

- **Important:** Made internal representation of `TIMESTAMP` values in InnoDB in 4.1 to be the same as in 4.0. This difference resulted in incorrect datetime values in `TIMESTAMP` columns in InnoDB tables after an upgrade from 4.0 to 4.1. (Bug #4492 [<http://bugs.mysql.com/4492>])  
**Warning: extra steps during upgrade required!** This means that if you are upgrading from 4.1.x, where  $x \leq 3$ , to 4.1.4 you should use `mysqldump` for saving and then restoring your

InnoDB tables with `TIMESTAMP` columns. No conversion is needed if you upgrade from 3.23 or 4.0 to 4.1.4 or later.

- Added a new startup option `innodb_locks_unsafe_for_binlog`. This option forces InnoDB not to use next-key locking in searches and index scans.
- Added `innodb_status_file` system variable to **mysqld** to control whether output from `SHOW INNODB STATUS` is written to a `innodb_status.<pid>` file in the data directory. By default, the file is not created. To create it, start **mysqld** with the `-innodb_status_file=1` option.
- Changes for NetWare to exit InnoDB gracefully on NetWare even in a case of an assertion failure, instead of intentionally crashing the **mysqld** server process.
- 'Gap' type row locks without the `LOCK_INSERT_INTENTION` flag do not need to wait for anything. This is because different users can have conflicting lock types on gaps. This change reduces unnecessary deadlocks.

Bugs fixed:

- Fixed a bug in `ON DELETE CASCADE` and `ON UPDATE CASCADE` foreign key constraints: long chains of cascaded operations would cause a stack overflow and crash the server. Cascaded operations are now limited to 15 levels. (Bug #4446 [<http://bugs.mysql.com/4446>])
- Increment the InnoDB watchdog timeout during `CHECK TABLE`. (Bug #2694 [<http://bugs.mysql.com/2694>])
- If you configure `innodb_additional_mem_pool_size` so small that InnoDB memory allocation spills over from it, then every 4 billionth spill may cause memory corruption. A symptom is a printout like below in the `.err` log.

```
InnoDB: Error: Mem area size is 0. Possibly a memory overrun of the
InnoDB: previous allocated area!
InnoDB: Apparent memory corruption: mem dump len 500; hex
```

- Fixed a glitch introduced in 4.0.18 and 4.1.2: in `SHOW TABLE STATUS` InnoDB systematically overestimated the row count by 1 if the table fit on a single 16 kB data page.
- InnoDB created temporary files with the C library function `tmpfile()`. On Windows, the files would be created in the root directory of the current file system. To correct this behavior, the invocations of `tmpfile()` were replaced with code that uses the function `create_temp_file()` in the MySQL portability layer. (Bug #3998 [<http://bugs.mysql.com/3998>])
- If we `RENAME`d a table, InnoDB forgot to load the foreign key constraints that reference the new table name, and forgot to check that they are compatible with the table.
- If there was little file I/O in InnoDB, but the insert buffer was used, it could happen that 'Pending normal aio reads' was bigger than 0, but the I/O handler thread did not get waken up in 600 seconds. This resulted in a hang, and an intentional crashing of **mysqld**.

### D.9.3. MySQL/InnoDB-4.1.3, June 28, 2004

Functionality added or changed:

- **Important:** Starting from MySQL 4.1.3, InnoDB uses the same character set comparison functions as MySQL for `non-latin1_swedish_ci` character strings that are not `BINARY`. This changes the sorting order of space and characters < ASCII(32) in those character sets. For `lat-`

`inl_swedish_ci` character strings and `BINARY` strings, InnoDB uses its own pad-spaces-at-end comparison method, which stays unchanged. If you have an InnoDB table created with MySQL 4.1.2 or earlier, with an index on a non-`latin1` character set (in the case of 4.1.0 and 4.1.1 with any character set) `CHAR/VARCHAR`/or `TEXT` column that is not `BINARY` but may contain characters `< ASCII(32)`, then you should do `ALTER TABLE` or `OPTIMIZE` table on it to **regenerate the index, after upgrading to MySQL 4.1.3 or later**.

- `OPTIMIZE TABLE` for InnoDB tables is now mapped to `ALTER TABLE` rather than to `ANALYZE TABLE`.
- Added an interface for storing the binlog offset in the InnoDB log and flushing the log.

Bugs fixed:

- The **critical bug in 4.1.2** (crash recovery skipping all `.ibd` files if you specify `innodb_file_per_table` on Unix) has been fixed. The bug was a combination of two bugs. Crash recovery ignored the files, because the attempt to lock them in the wrong mode failed. From now on, locks are only obtained for regular files opened in read/write mode, and crash recovery stops if an `.ibd` file for a table exists in a database directory but is unaccessible.
- Do not remember the original `select_lock_type` inside `LOCK TABLES`. (Bug #4047 [<http://bugs.mysql.com/4047>])
- The special meaning of the table names `innodb_monitor`, `innodb_lock_monitor`, `innodb_tablespace_monitor`, `innodb_table_monitor`, and `innodb_validate` in `CREATE TABLE` and `DROP TABLE` statements was accidentally removed in MySQL/InnoDB-4.1.2. The diagnostic functions attached to these special table names (see Section 15.12.1, “`SHOW INNODB STATUS` and the InnoDB Monitors”) are accessible again in MySQL/InnoDB-4.1.3.
- When the private SQL parser of InnoDB was modified in MySQL/InnoDB-4.0.19 in order to allow the use of the apostrophe (') in table and column names, the fix relied on a previously unused function `mem_realloc()`, whose implementation was incorrect. As a result, InnoDB can incorrectly parse column and table names as the empty string. The InnoDB `realloc()` implementation has been corrected in MySQL/InnoDB-4.1.3.
- In a clean-up of MySQL/InnoDB-4.1.2, the code for invalidating the query cache was broken. Now the query cache should be correctly invalidated for tables affected by `ON UPDATE CASCADE` or `ON DELETE CASCADE` constraints.
- Fixed a bug: in `LIKE 'abc%'`, the `'%'` did not match the empty string if the character set was not `latin1_swedish_ci`. This bug was fixed by changing the sorting order in these character sets. See the above note about data conversion in 4.1.3.

## D.9.4. MySQL/InnoDB-4.1.2, May 30, 2004

**NOTE:** CRITICAL BUG in 4.1.2 if you specify `innodb_file_per_table` in `my.cnf` on Unix. In crash recovery InnoDB skips the crash recovery for all `.ibd` files and those tables become CORRUPT! The symptom is a message `Unable to lock ...ibd with lock 1, error: 9: fcntl: Bad file descriptor` in the `.err` log in crash recovery.

Functionality added or changed:

- Support multiple character sets. Note that tables created in other collations than `latin1_swedish_ci` cannot be accessed in MySQL/InnoDB 4.0.
- Automatically create a suitable index on a `FOREIGN KEY`, if the user does not create one. Removes most of the cases of `Error 1005 (errno 150)` in table creation.

- Do not assert in `log0log.c`, line 856 if `ib_logfiles` are too small for `innodb_thread_concurrency`. Instead, print instructions how to adjust `my.cnf` and call `exit(1)`.
- If MySQL tries to `SELECT` from an InnoDB table without setting any table locks, print a descriptive error message and assert; some subquery bugs were of this type.
- Allow a key part length in InnoDB to be up to 3,500 bytes; this is needed so that you can create an index on a column with 255 UTF-8 characters.
- All new features from InnoDB-4.0.17, InnoDB-4.0.18, InnoDB-4.0.19 and InnoDB-4.0.20.

Bugs fixed:

- If you configure `innodb_additional_mem_pool_size` so small that InnoDB memory allocation spills over from it, then every 4 billionth spill may cause memory corruption. A symptom is a printout like below in the `.err` log.  

```
InnoDB: Error: Mem area size is 0. Possibly a memory overrun of the
InnoDB: previous allocated area!
InnoDB: Apparent memory corruption: mem dump len 500; hex
```
- Improved portability to 64-bit platforms, especially Win64.
- Fixed an assertion failure when a purge of a table was not possible because of missing `.ibd` file.
- Fixed a bug: do not retrieve all columns in a table if we only need the 'ref' of the row (usually, the `PRIMARY KEY`) to calculate an `ORDER BY`. (Bug #1942 [<http://bugs.mysql.com/1942>])
- On Unix-like systems, obtain an exclusive advisory lock on InnoDB files, to prevent corruption when multiple instances of MySQL are running on the same set of data files. The Windows version of InnoDB currently takes a mandatory lock on the files. (Bug #3608 [<http://bugs.mysql.com/3608>])
- Added a missing space to the output format of `SHOW INNODB STATUS`; reported by Jocelyn Fournier.
- All bugfixes from InnoDB-4.0.17, InnoDB-4.0.18, InnoDB-4.0.19 and InnoDB-4.0.20.

## D.9.5. MySQL/InnoDB-4.0.20, May 18, 2004

Bugs fixed:

- Apostrophe characters now are recognized by the internal InnoDB parser and can be used within quoted table and column identifiers in `FOREIGN KEY` clauses.
- Make `LOCK TABLE` aware of InnoDB row-level locks and InnoDB aware of locks set with `LOCK TABLE`. (Bug #3299 [<http://bugs.mysql.com/3299>])
- Fixed race conditions in `SHOW INNODB STATUS`. (Bug #3596 [<http://bugs.mysql.com/3596>])

## D.9.6. MySQL/InnoDB-4.0.19, May 4, 2004

Functionality added or changed:

- Better error message when the server has to crash because the buffer pool is exhausted by the lock table or the adaptive hash index.
- Print always the count of pending `pread()` and `pwrite()` calls if there is a long semaphore wait.
- Improve space utilization when rows of 1,500 to 8,000 bytes are inserted in the order of the primary key.
- Remove potential buffer overflow errors by sending diagnostic output to `stderr` or files instead of `stdout` or fixed-size memory buffers. As a side effect, the output of `SHOW INNODB STATUS` is written to a file `<datadir>/innodb.status.<pid>` every 15 seconds.

Bugs fixed:

- Fixed a bug: `DROP DATABASE` did not work if `FOREIGN KEY` references were defined within the database. (Bug #3058 [<http://bugs.mysql.com/3058>])
- Remove unnecessary files, functions and variables. Many of these were needed in the standalone version of InnoDB. Remove debug functions and variables from non-debug build.
- Add diagnostic code to analyze an assertion failure in `ha_innodb.cc` on line 2020 reported by a user. (Bug #2903 [<http://bugs.mysql.com/2903>])
- Fixed a bug: in a `FOREIGN KEY, ON UPDATE CASCADE` was not triggered if the update changed a string to another value identical in alphabetical ordering, for example, 'abc' -> 'aBc'.
- Protect the reading of the latest foreign key error explanation buffer with a mutex; in theory, a race condition could cause `SHOW INNODB STATUS` print garbage characters after the error info.
- Fixed a bug: The row count and key cardinality estimate was grossly too small if each clustered index page only contained one record.
- Parse `CONSTRAINT FOREIGN KEY` correctly. (Bug #3332 [<http://bugs.mysql.com/3332>])
- Fixed a memory corruption bug on Windows. The bug is present in all InnoDB versions in Windows, but it depends on how the linker places a static array in `srv0srv.c`, whether the bug shows itself. 4 bytes were overwritten with a pointer to a statically allocated string 'get windows aio return value'.
- Fix a glitch reported by Philippe Lewicki on the general mailing list: do not print a warning to the `.err` log if `read_key` fails with a lock wait timeout error 146.
- Allow quotes to be embedded in strings in the private SQL parser of InnoDB, so that '' can be used in InnoDB table and column names. Display quotes within identifiers properly.
- Debugging: Allow `UNIV_SYNC_DEBUG` to be disabled while `UNIV_DEBUG` is enabled.
- Debugging: Handle magic numbers in a more consistent way.

## D.9.7. MySQL/InnoDB-4.0.18, February 13, 2004

- Do not allow dropping a table referenced by a `FOREIGN KEY` constraint, unless the user does `SET FOREIGN_KEY_CHECKS=0`. The error message here is somewhat misleading ``Cannot delete or update a parent row...'', and must be changed in a future version 4.1.x.
- Make InnoDB to remember the `CONSTRAINT` name given by a user for a `FOREIGN KEY`.

- Change the print format of FOREIGN KEY constraints spanning multiple databases to ``db_name`.`tbl_name``. But when parsing them, we must also accept ``db_name.tbl_name``, because that was the output format in < 4.0.18.
- An optimization in locking: If AUTOCOMMIT=1, then we do not need to make a plain SELECT set shared locks even on the SERIALIZABLE isolation level, because we know that the transaction is read-only. A read-only transaction can always be performed on the REPEATABLE READ level, and that does not endanger the serializability.
- Implement an automatic downgrade from >= 4.1.1 -> 4.0.18 if the user has not created tables in .ibd files or used other 4.1.x features. **Consult** the manual section on **multiple tablespaces** carefully if you want to downgrade!
- Fixed a bug: MySQL should not allow REPLACE to internally perform an UPDATE if the table is referenced by a FOREIGN KEY. The MySQL manual states that REPLACE must resolve a duplicate-key error semantically with DELETE(s) + INSERT, and not by an UPDATE. In versions < 4.0.18 and < 4.1.2, MySQL could resolve a duplicate key conflict in REPLACE by doing an UPDATE on the existing row, and FOREIGN KEY checks could behave in a semantically wrong way. (Bug #2418 [<http://bugs.mysql.com/2418>])
- Fixed a bug: generate FOREIGN KEY constraint identifiers locally for each table, in the form `db_name/tbl_name_ibfk_number`. If the user gives the constraint name explicitly, then remember it. These changes should ensure that foreign key id's in a slave are the same as in the master, and DROP FOREIGN KEY does not break replication. (Bug #2167 [<http://bugs.mysql.com/2167>])
- Fixed a bug: allow quoting of identifiers in InnoDB's FOREIGN KEY definitions with a backtick ( ` ) and a double quote ( " ). You can now use also spaces in table and column names, if you quote the identifiers. (Bug #1725 [<http://bugs.mysql.com/1725>], Bug #2424 [<http://bugs.mysql.com/2424>])
- Fixed a bug: FOREIGN KEY ... ON UPDATE/DELETE NO ACTION must check the foreign key constraint, not ignore it. Since we do not have deferred constraints in InnoDB, this bugfix makes InnoDB to check NO ACTION constraints immediately, like it checks RE- STRICT constraints.
- Fixed a bug: InnoDB crashed in RENAME TABLE if `db_name.tbl_name` is shorter than 5 characters. (Bug #2689 [<http://bugs.mysql.com/2689>])
- Fixed a bug: in SHOW TABLE STATUS, InnoDB row count and index cardinality estimates wrapped around at 512 million in 32-bit computers. Note that unless MySQL is compiled with the BIG\_TABLES option, they still wrap around at 4 billion.
- Fixed a bug: If there was a UNIQUE secondary index, and NULL values in that unique index, then with the IS NULL predicate, InnoDB returned only the first matching row, though there can be many. This bug was introduced in 4.0.16. (Bug #2483 [<http://bugs.mysql.com/2483>])

## D.9.8. MySQL/InnoDB-5.0.0, December 24, 2003

- **Important note:** If you upgrade to MySQL 4.1.1 or higher, it is difficult to downgrade back to 4.0 or 4.1.0! That is because, for earlier versions, InnoDB is not aware of multiple tablespaces.
- InnoDB in 5.0.0 is essentially the same as InnoDB-4.1.1 with the bugfixes of InnoDB-4.0.17 included.

## D.9.9. MySQL/InnoDB-4.0.17, December 17, 2003

- Fixed a bug: If you created a column prefix secondary index and updated it so that the last char-

acters in the column prefix were spaces, InnoDB would assert in `row0upd.c`, line 713. The same assertion failed if you updated a column in an ordinary secondary index so that the new value was alphabetically equivalent, but had a different length. This could happen, for example, in the UTF8 character set if you updated a letter to its accented or umlaut form.

- Fixed a bug: InnoDB could think that a secondary index record was not locked though it had been updated to an alphabetically equivalent value, for example, 'abc' -> 'aBc'.
- Fixed a bug: If you updated a secondary index column to an alphabetically equivalent value, and rolled back your update, InnoDB failed to restore the field in the secondary index to its original value.
- There are still several outstanding non-critical bugs reported in the MySQL bugs database. Their fixing has been delayed, because resources were allocated to the 4.1.1 release.

## D.9.10. MySQL/InnoDB-4.1.1, December 4, 2003

- **Important note:** If you upgrade to MySQL 4.1.1 or higher, you cannot downgrade to a version lower than 4.1.1 any more! That is because, for earlier versions, InnoDB is not aware of multiple tablespaces.
- Multiple tablespaces now available for InnoDB. You can store each InnoDB type table and its indexes into a separate `.ibd` file into a MySQL database directory, into the same directory where the `.frm` file is stored.
- The MySQL query cache now works for InnoDB tables also if `AUTOCOMMIT=0`, or the statements are enclosed inside `BEGIN . . . COMMIT`.
- Reduced InnoDB memory consumption by a few megabytes if one sets the buffer pool size < 8MB.
- You can use raw disk partitions also in Windows.

## D.9.11. MySQL/InnoDB-4.0.16, October 22, 2003

- Fixed a bug: in contrary to what was said in the manual, in a locking read InnoDB set two record locks if a unique exact match search condition was used on a multi-column unique key. For a single column unique key it worked right.
- Fixed a bug: If you used the rename trick `#sql... -> rsql...` to recover a temporary table, InnoDB asserted in `row_mysql_lock_data_dictionary()`.
- There are several outstanding non-critical bugs reported in the MySQL bugs database. Their fixing has been delayed, because resources are allocated to the upcoming 4.1.1 release.

## D.9.12. MySQL/InnoDB-3.23.58, September 15, 2003

- Fixed a bug: InnoDB could make the index page directory corrupt in the first B-tree page splits after **mysqld** startup. A symptom would be an assertion failure in `page0page.c`, in function `page_dir_find_slot()`.
- Fixed a bug: InnoDB could in rare cases return an extraneous row if a rollback, purge, and a `SELECT` coincided.
- Fixed a possible hang over the `bt0sea.c` latch if `SELECT` was used inside `LOCK TABLES`.

- Fixed a bug: If a single DELETE statement first managed to delete some rows and then failed in a FOREIGN KEY error or a Table is full error, MySQL did not roll back the whole SQL statement as it should.

### D.9.13. MySQL/InnoDB-4.0.15, September 10, 2003

- Fixed a bug: If you updated a row so that the 8000 byte maximum length (without BLOB and TEXT) was exceeded, InnoDB simply removed the record from the clustered index. In a similar insert, InnoDB would leak reserved file space extents, which would only be freed at the next `mysqld` startup.
- Fixed a bug: If you used big BLOB values, and your log files were relatively small, InnoDB could in a big BLOB operation temporarily write over the log produced after the latest checkpoint. If InnoDB would crash at that moment, then the crash recovery would fail, because InnoDB would not be able to scan the log even up to the latest checkpoint. Starting from this version, InnoDB tries to ensure the latest checkpoint is young enough. If that is not possible, InnoDB prints a warning to the `.err` log of MySQL and advises you to make the log files bigger.
- Fixed a bug: setting `innodb_fast_shutdown=0` had no effect.
- Fixed a bug introduced in 4.0.13: If a CREATE TABLE ended in a comment, that could cause a memory overrun.
- Fixed a bug: If InnoDB printed Operating system error number `..` in a file operation to the `.err` log in Windows, the error number explanation was wrong. Workaround: look at section 13.2 of <http://www.innodb.com/ibman.php> about Windows error numbers.
- Fixed a bug: If you created a column prefix PRIMARY KEY like in `t(a CHAR(200), PRIMARY KEY (a(10)))` on a fixed-length CHAR column, InnoDB would crash even in a simple SELECT. A CHECK TABLE would report the table as corrupt, also in the case where the created key was not PRIMARY.

### D.9.14. MySQL/InnoDB-4.0.14, July 22, 2003

- InnoDB now supports the SAVEPOINT and ROLLBACK TO SAVEPOINT SQL statements. See <http://www.innodb.com/ibman.php#Savepoints> for the syntax.
- You can now create column prefix keys like in `CREATE TABLE t (a BLOB, INDEX (a(10)))`.
- You can also use `O_DIRECT` as the `innodb_flush_method` on the latest versions of Linux and FreeBSD. Beware of possible bugs in those operating systems, though.
- Fixed the checksum calculation of data pages. Previously most OS file system corruption went unnoticed. Note that if you downgrade from version  $\geq 4.0.14$  to an earlier version  $< 4.0.14$  then in the first startup(s) InnoDB prints warnings:

```
InnoDB: Warning: An inconsistent page in the doublewrite buffer
InnoDB: space id 2552202359 page number 8245, 127'th page in dblwr buf.
```

but that is not dangerous and can be ignored.

- Modified the buffer pool replacement algorithm so that it tries to flush modified pages if there are no replaceable pages in the last 10 % of the LRU list. This can reduce disk I/O if the workload is a mixture of reads and writes.
- The buffer pool checkpoint flush algorithm now tries to flush also close neighbors of the page at

the end of the flush list. This can speed up database shutdown, and can also speed up disk writes if InnoDB log files are very small compared to the buffer pool size.

- In 4.0.13 we made `SHOW INNODB STATUS` to print detailed info on the latest `UNIQUE KEY` error, but storing that information could slow down `REPLACE` significantly. We no longer store or print the info.
- Fixed a bug: `SET FOREIGN_KEY_CHECKS=0` was not replicated properly in the MySQL replication. The fix will not be backported to 3.23.
- Fixed a bug: the parameter `innodb_max_dirty_pages_pct` forgot to take into account the free pages in the buffer pool. This could lead to excessive flushing even though there were lots of free pages in the buffer pool. Workaround: `SET GLOBAL innodb_max_dirty_pages_pct = 100`.
- Fixed a bug: If there were big index scans then a file read request could starve and InnoDB could assert because of a very long semaphore wait.
- Fixed a bug: If `AUTOCOMMIT=1` then inside `LOCK TABLES` MySQL failed to do the commit after an updating SQL statement if binary logging was not on, and for `SELECT` statements did not commit regardless of binary logging state.
- Fixed a bug: InnoDB could make the index page directory corrupt in the first B-tree page splits after a `mysqld` startup. A symptom would be an assertion in `page0page.c`, in function `page_dir_find_slot()`.
- Fixed a bug: If in a `FOREIGN KEY` with an `UPDATE CASCADE` clause the parent column was of a different internal storage length than the child column, then a cascaded update would make the column length wrong in the child table and corrupt the child table. Because of MySQL's 'silent column specification changes' a fixed-length `CHAR` column can change internally to a `VARCHAR` and cause this error.
- Fixed a bug: If a non-`latin1` character set was used and if in a `FOREIGN KEY` the parent column was of a different internal storage length than the child column, then all inserts to the child table would fail in a foreign key error.
- Fixed a bug: InnoDB could complain that it cannot find the clustered index record, or in rare cases return an extraneous row if a rollback, purge, and a `SELECT` coincided.
- Fixed a possible hang over the `btr0sea.c` latch if `SELECT` was used inside `LOCK TABLES`.
- Fixed a bug: contrary to what the release note of 4.0.13 said, the group commit still did not work if the MySQL binary logging was on.
- Fixed a bug: `os_event_wait()` did not work properly in Unix, which might have caused starvation in various log operations.
- Fixed a bug: If a single `DELETE` statement first managed to delete some rows and then failed in a `FOREIGN KEY` error or a `Table is full` error, MySQL did not roll back the whole SQL statement as it should, and also wrote the failed statement to the binary log, reporting there a non-zero `error_code`.
- Fixed a bug: the maximum allowed number of columns in a table is 1000, but InnoDB did not check that limit in `CREATE TABLE`, and a subsequent `INSERT` or `SELECT` from that table could cause an assertion.

## D.9.15. MySQL/InnoDB-3.23.57, June 20, 2003

- Changed the default value of `innodb_flush_log_at_trx_commit` from 0 to 1. If you have not specified it explicitly in your `my.cnf`, and your application runs much slower with this new release, it is because the value 1 causes a log flush to disk at each transaction commit.

- Fixed a bug: InnoDB forgot to call `pthread_mutex_destroy()` when a table was dropped. That could cause memory leakage on FreeBSD and other non-Linux Unixes.
- Fixed a bug: MySQL could erroneously return 'Empty set' if InnoDB estimated an index range size to 0 records though the range was not empty; MySQL also failed to do the next-key locking in the case of an empty index range.
- Fixed a bug: `GROUP BY` and `DISTINCT` could treat NULL values unequal.

## D.9.16. MySQL/InnoDB-4.0.13, May 20, 2003

- InnoDB now supports `ALTER TABLE DROP FOREIGN KEY`. You have to use `SHOW CREATE TABLE` to find the internally generated foreign key ID when you want to drop a foreign key.
- `SHOW INNODB STATUS` now prints detailed information of the latest detected `FOREIGN KEY` and `UNIQUE KEY` errors. If you do not understand why InnoDB gives the error 150 from a `CREATE TABLE`, you can use this statement to study the reason.
- `ANALYZE TABLE` now works also for InnoDB type tables. It makes 10 random dives to each of the index trees and updates index cardinality estimates accordingly. Note that because these are only estimates, repeated runs of `ANALYZE TABLE` may produce different numbers. MySQL uses index cardinality estimates only in join optimization. If some join is not optimized in the right way, you may try using `ANALYZE TABLE`.
- InnoDB group commit capability now works also when MySQL binary logging is switched on. There have to be  $> 2$  client threads for the group commit to become active.
- Changed the default value of `innodb_flush_log_at_trx_commit` from 0 to 1. If you have not specified it explicitly in your `my.cnf`, and your application runs much slower with this new release, it is because the value 1 causes a log flush to disk at each transaction commit.
- Added a new global settable MySQL system variable `innodb_max_dirty_pages_pct`. It is an integer in the range 0 - 100. The default is 90. The main thread in InnoDB tries to flush pages from the buffer pool so that at most this many percents are not yet flushed at any time.
- If `innodb_force_recovery=6`, do not let InnoDB do repair of corrupt pages based on the doublewrite buffer.
- InnoDB startup now happens faster because it does not set the memory in the buffer pool to zero.
- Fixed a bug: The InnoDB parser for `FOREIGN KEY` definitions was confused by the keywords 'foreign key' inside MySQL comments.
- Fixed a bug: If you dropped a table to which there was a `FOREIGN KEY` reference, and later created the same table with non-matching column types, InnoDB could assert in `dict0load.c`, in function `dict_load_table()`.
- Fixed a bug: `GROUP BY` and `DISTINCT` could treat NULL values as not equal. MySQL also failed to do the next-key locking in the case of an empty index range.
- Fixed a bug: Do not commit the current transaction when a MyISAM table is updated; this also makes `CREATE TABLE` not to commit an InnoDB transaction, even when binary logging is enabled.
- Fixed a bug: We did not allow `ON DELETE SET NULL` to modify the same table where the delete was made; we can allow it because that cannot produce infinite loops in cascaded operations.
- Fixed a bug: Allow `HANDLER PREV` and `NEXT` also after positioning the cursor with a unique

search on the primary key.

- Fixed a bug: If `MIN()` or `MAX()` resulted in a deadlock or a lock wait timeout, MySQL did not return an error, but returned `NULL` as the function value.
- Fixed a bug: InnoDB forgot to call `pthread_mutex_destroy()` when a table was dropped. That could cause memory leakage on FreeBSD and other non-Linux Unix systems.

### D.9.17. MySQL/InnoDB-4.1.0, April 3, 2003

- InnoDB now supports up to 64GB of buffer pool memory in a Windows 32-bit Intel computer. This is possible because InnoDB can use the AWE extension of Windows to address memory over the 4GB limit of a 32-bit process. A new startup variable `innodb_buffer_pool_awe_mem_mb` enables AWE and sets the size of the buffer pool in megabytes.
- Reduced the size of buffer headers and the lock table. InnoDB uses 2 % less memory.

### D.9.18. MySQL/InnoDB-3.23.56, March 17, 2003

- Fixed a major bug in InnoDB query optimization: queries of type `SELECT ... WHERE indexcolumn < x` and `SELECT ... WHERE indexcolumn > x` could cause a table scan even if the selectivity would have been very good.
- Fixed a potential bug if MySQL calls `store_lock` with `TL_IGNORE` in the middle of a query.

### D.9.19. MySQL/InnoDB-4.0.12, March 18, 2003

- In crash recovery InnoDB now prints the progress in percents of a transaction rollback.
- Fixed a bug/feature: If your application program used `mysql_use_result()`, and used `>= 2` connections to send SQL queries, it could deadlock on the adaptive hash S-latch in `btr0sea.c`. Now **mysqld** releases the S-latch whenever it passes data from a `SELECT` to the client.
- Fixed a bug: MySQL could erroneously return 'Empty set' if InnoDB estimated an index range size to 0 records though the range was not empty; MySQL also failed to do the next-key locking in the case of an empty index range.

### D.9.20. MySQL/InnoDB-4.0.11, February 25, 2003

- Fixed a bug introduced in 4.0.10: `SELECT ... FROM ... ORDER BY ... DESC` could hang in an infinite loop.
- An outstanding bug: `SET FOREIGN_KEY_CHECKS=0` is not replicated properly in the MySQL replication.

### D.9.21. MySQL/InnoDB-4.0.10, February 4, 2003

- In `INSERT INTO t1 SELECT ... FROM t2 WHERE ...` MySQL previously set a table level read lock on `t2`. This lock is now removed.

- Increased SHOW INNODB STATUS maximum printed length to 200KB.
- Fixed a major bug in InnoDB query optimization: queries of type SELECT ... WHERE index-column < x and SELECT ... WHERE indexcolumn > x could cause a table scan even if the selectivity would have been very good.
- Fixed a bug: purge could cause a hang in a BLOB table where the primary key index tree was of height 1. Symptom: semaphore waits caused by an X-latch set in btr\_free\_externally\_stored\_field().
- Fixed a bug: using InnoDB HANDLER commands on a fresh handle crashed **mysqld** in ha\_innobase::change\_active\_index().
- Fixed a bug: If MySQL estimated a query in the middle of a SELECT statement, InnoDB could hang on the adaptive hash index latch in btr0sea.c.
- Fixed a bug: InnoDB could report table corruption and assert in page\_dir\_find\_owner\_slot() if an adaptive hash index search coincided with purge or an insert.
- Fixed a bug: some filesystem snapshot tool in Windows 2000 could cause an InnoDB file write to fail with error 33 ERROR\_LOCK\_VIOLATION. In synchronous writes InnoDB now retries the write 100 times at 1 second intervals.
- Fixed a bug: REPLACE INTO t1 SELECT ... did not work if t1 has an auto-inc column.
- An outstanding bug: SET FOREIGN\_KEY\_CHECKS=0 is not replicated properly in the MySQL replication.

## D.9.22. MySQL/InnoDB-3.23.55, January 24, 2003

- In INSERT INTO t1 SELECT ... FROM t2 WHERE ... MySQL previously set a table level read lock on t2. This lock is now removed.
- Fixed a bug: If the combined size of InnoDB log files was >= 2GB in a 32-bit computer, InnoDB would write log in a wrong position. That could make crash recovery and InnoDB Hot Backup to fail in log scan.
- Fixed a bug: index cursor restoration could theoretically fail.
- Fixed a bug: an assertion in btr0sea.c, in function btr\_search\_info\_update\_slow could theoretically fail in a race of 3 threads.
- Fixed a bug: purge could cause a hang in a BLOB table where the primary key index tree was of height 1. Symptom: semaphore waits caused by an X-latch set in btr\_free\_externally\_stored\_field().
- Fixed a bug: If MySQL estimated a query in the middle of a SELECT statement, InnoDB could hang on the adaptive hash index latch in btr0sea.c.
- Fixed a bug: InnoDB could report table corruption and assert in page\_dir\_find\_owner\_slot() if an adaptive hash index search coincided with purge or an insert.
- Fixed a bug: some filesystem snapshot tool in Windows 2000 could cause an InnoDB file write to fail with error 33 ERROR\_LOCK\_VIOLATION. In synchronous writes InnoDB now retries the write 100 times at 1 second intervals.
- An outstanding bug: SET FOREIGN\_KEY\_CHECKS=0 is not replicated properly in the MySQL replication. The fix appears in 4.0.11 and probably will not be backported to 3.23.
- Fixed bug in InnoDB page0cur.c file in function page\_cur\_search\_with\_match which caused InnoDB to remain on the same page forever. This bug is evident only in tables with

more than one page.

### D.9.23. MySQL/InnoDB-4.0.9, January 14, 2003

- Removed the warning message: 'InnoDB: Out of memory in additional memory pool.'
- Fixed a bug: If the combined size of InnoDB log files was  $\geq$  2GB in a 32-bit computer, InnoDB would write log in a wrong position. That could make crash recovery and InnoDB Hot Backup to fail.
- Fixed a bug: index cursor restoration could theoretically fail.

### D.9.24. MySQL/InnoDB-4.0.8, January 7, 2003

- InnoDB now supports also FOREIGN KEY (...) REFERENCES ...(...) [ON UPDATE CASCADE | ON UPDATE SET NULL | ON UPDATE RESTRICT | ON UPDATE NO ACTION].
- Tables and indexes now reserve 4 % less space in the tablespace. Also existing tables reserve less space. By upgrading to 4.0.8 you should see more free space in "InnoDB free" in SHOW TABLE STATUS.
- Fixed bugs: updating the PRIMARY KEY of a row would generate a foreign key error on all FOREIGN KEYS which referenced secondary keys of the row to be updated. Also, if a referencing FOREIGN KEY constraint only referenced the first columns in an index, and there were more columns in that index, updating the additional columns generated a foreign key error.
- Fixed a bug: If an index contains some column twice, and that column is updated, the table becomes corrupt. From now on InnoDB prevents creation of such indexes.
- Fixed a bug: removed superfluous error 149 and 150 printouts from the .err log when a locking SELECT caused a deadlock or a lock wait timeout.
- Fixed a bug: an assertion in btr0sea.c, in function btr\_search\_info\_update\_slow could theoretically fail in a race of 3 threads.
- Fixed a bug: one could not switch a session transaction isolation level back to REPEATABLE READ after setting it to something else.

### D.9.25. MySQL/InnoDB-4.0.7, December 26, 2002

- InnoDB in 4.0.7 is essentially the same as in 4.0.6.

### D.9.26. MySQL/InnoDB-4.0.6, December 19, 2002

- Since innodb\_log\_arch\_dir has no relevance under MySQL, there is no need to specify it any more in my.cnf.
- LOAD DATA INFILE in AUTOCOMMIT=1 mode no longer does implicit commits for each 1MB of written binary log.
- Fixed a bug introduced in 4.0.4: LOCK TABLES ... READ LOCAL should not set row locks on the rows read. This caused deadlocks and lock wait timeouts in mysqldump.

- Fixed two bugs introduced in 4.0.4: in `AUTO_INCREMENT`, `REPLACE` could cause the counter to be left 1 too low. A deadlock or a lock wait timeout could cause the same problem.
- Fixed a bug: `TRUNCATE` on a `TEMPORARY` table crashed `InnoDB`.
- Fixed a bug introduced in 4.0.5: If binary logging was not switched on, `INSERT INTO ... SELECT ...` or `CREATE TABLE ... SELECT ...` could cause `InnoDB` to hang on a semaphore created in `btr0sea.c`, line 128. Workaround: switch binary logging on.
- Fixed a bug: in replication issuing `SLAVE STOP` in the middle of a multiple-statement transaction could cause that `SLAVE START` would only perform a part of the transaction. A similar error could occur if the slave crashed and was restarted.

## D.9.27. MySQL/InnoDB-3.23.54, December 12, 2002

- Fixed a bug: the `InnoDB` range estimator greatly exaggerated the size of a short index range if the paths to the endpoints of the range in the index tree happened to branch in the root. This could cause unnecessary table scans in SQL queries.
- Fixed a bug: `ORDER BY` could fail if you had not created a primary key to a table, but had defined several indexes of which at least one was a `UNIQUE` index with all its columns declared as `NOT NULL`.
- Fixed a bug: a lock wait timeout in connection with `ON DELETE CASCADE` could cause corruption in indexes.
- Fixed a bug: If a `SELECT` was done with a unique key from a primary index, and the search matched to a delete-marked record, `InnoDB` could erroneously return the `NEXT` record.
- Fixed a bug introduced in 3.23.53: `LOCK TABLES ... READ LOCAL` should not set row locks on the rows read. This caused deadlocks and lock wait timeouts in `mysqldump`.
- Fixed a bug: If an index contains some column twice, and that column is updated, the table becomes corrupt. From now on `InnoDB` prevents creation of such indexes.

## D.9.28. MySQL/InnoDB-4.0.5, November 18, 2002

- `InnoDB` now supports also transaction isolation levels `READ COMMITTED` and `READ UNCOMMITTED`. `READ COMMITTED` more closely emulates Oracle and makes porting of applications from Oracle to MySQL easier.
- Deadlock resolution is now selective: we try to pick as victims transactions with less modified or inserted rows.
- `FOREIGN KEY` definitions are now aware of the `lower_case_table_names` setting in `my.cnf`.
- `SHOW CREATE TABLE` does not output the database name to a `FOREIGN KEY` definition if the referred table is in the same database as the table.
- `InnoDB` does a consistency check to most index pages before writing them to a data file.
- If you set `innodb_force_recovery > 0`, `InnoDB` tries to jump over corrupt index records and pages when doing `SELECT * FROM table`. This helps in dumping.
- `InnoDB` now again uses asynchronous unbuffered I/O in Windows 2000 and XP; only unbuffered simulated async I/O in NT, 95/98/ME.
- Fixed a bug: the `InnoDB` range estimator greatly exaggerated the size of a short index range if the paths to the endpoints of the range in the index tree happened to branch in the root. This

could cause unnecessary table scans in SQL queries. The fix is also backported to 3.23.54.

- Fixed a bug present in 3.23.52, 4.0.3, 4.0.4: InnoDB startup could take very long or even crash on some Windows 95/98/ME computers.
- Fixed a bug: the AUTO-INC lock was held to the end of the transaction if it was granted after a lock wait. This could cause unnecessary deadlocks.
- Fixed a bug: If SHOW INNODB STATUS, innodb\_monitor, or innodb\_lock\_monitor had to print several hundred transactions in one report, and the output became truncated, InnoDB would hang, printing to the error log many waits for a mutex created at srv0srv.c, line 1621.
- Fixed a bug: SHOW INNODB STATUS on Unix always reported average file read size as 0 bytes.
- Fixed a potential bug in 4.0.4: InnoDB now does ORDER BY ... DESC like MyISAM.
- Fixed a bug: DROP TABLE could cause crash or a hang if there was a rollback concurrently running on the table. The fix will be backported to 3.23 only if this appears a real problem for users.
- Fixed a bug: ORDER BY could fail if you had not created a primary key to a table, but had defined several indexes of which at least one was a UNIQUE index with all its columns declared as NOT NULL.
- Fixed a bug: a lock wait timeout in connection with ON DELETE CASCADE could cause corruption in indexes.
- Fixed a bug: If a SELECT was done with a unique key from a primary index, and the search matched to a delete-marked record, InnoDB could return the NEXT record.
- Outstanding bugs: in 4.0.4 two bugs were introduced to AUTO\_INCREMENT. REPLACE can cause the counter to be left 1 too low. A deadlock or a lock wait timeout can cause the same problem. These are fixed in 4.0.6.

## D.9.29. MySQL/InnoDB-3.23.53, October 9, 2002

- We again use unbuffered disk I/O to data files in Windows. Windows XP and Windows 2000 read performance seems to be very poor with normal I/O.
- Tuned range estimator so that index range scans are preferred over full index scans.
- Allow dropping and creating a table even if innodb\_force\_recovery is set. One can use this to drop a table which would cause a crash in rollback or purge, or if a failed table import causes a runaway rollback in recovery.
- Fixed a bug present in 3.23.52, 4.0.3, 4.0.4: InnoDB startup could take very long or even crash on some Windows 95/98/ME computers.
- Fixed a bug: fast shutdown (which is the default) sometimes was slowed down by purge and insert buffer merge.
- Fixed a bug: doing a big SELECT from a table where no rows were visible in a consistent read could cause a very long (> 600 seconds) semaphore wait in btr0cur.c line 310.
- Fixed a bug: the AUTO-INC lock was held to the end of the transaction if it was granted after a lock wait. This could cause unnecessary deadlocks.
- Fixed a bug: If you created a temporary table inside LOCK TABLES, and used that temporary table, that caused an assertion failure in ha\_innobase.cc.

- Fixed a bug: If `SHOW INNODB STATUS`, `innodb_monitor`, or `innodb_lock_monitor` had to print several hundred transactions in one report, and the output became truncated, `InnoDB` would hang, printing to the error log many waits for a mutex created at `srv0srv.c`, line 1621.
- Fixed a bug: `SHOW INNODB STATUS` on Unix always reported average file read size as 0 bytes.

### D.9.30. MySQL/InnoDB-4.0.4, October 2, 2002

- We again use unbuffered disk I/O in Windows. Windows XP and Windows 2000 read performance seems to be very poor with normal I/O.
- Increased the maximum key length of `InnoDB` tables from 500 to 1024 bytes.
- Increased the table comment field in `SHOW TABLE STATUS` so that up to 16000 characters of foreign key definitions can be printed there.
- The auto-increment counter is no longer incremented if an insert of a row immediately fails in an error.
- Allow dropping and creating a table even if `innodb_force_recovery` is set. One can use this to drop a table which would cause a crash in rollback or purge, or if a failed table import causes a runaway rollback in recovery.
- Fixed a bug: Using `ORDER BY primarykey DESC` in 4.0.3 causes an assertion failure in `btr0pcur.c`, line 203.
- Fixed a bug: fast shutdown (which is the default) sometimes was slowed down by purge and insert buffer merge.
- Fixed a bug: doing a big `SELECT` from a table where no rows were visible in a consistent read could cause a very long (> 600 seconds) semaphore wait in `btr0cur.c` line 310.
- Fixed a bug: If the MySQL query cache was used, it did not get invalidated by a modification done by `ON DELETE CASCADE` or `...SET NULL`.
- Fixed a bug: If you created a temporary table inside `LOCK TABLES`, and used that temporary table, that caused an assertion failure in `ha_innodb.cc`.
- Fixed a bug: If you set `innodb_flush_log_at_trx_commit` to 1, `SHOW VARIABLES` would show its value as 16 million.

### D.9.31. MySQL/InnoDB-4.0.3, August 28, 2002

- Removed unnecessary deadlocks when inserts have to wait for a locking read, update, or delete to release its next-key lock.
- The MySQL `HANDLER SQL` commands now work also for `InnoDB` type tables. `InnoDB` does the `HANDLER` reads always as consistent reads. `HANDLER` is a direct access path to read individual indexes of tables. In some cases, `HANDLER` can be used as a substitute of server-side cursors.
- Fixed a bug in 4.0.2: even a simple insert could crash the AIX version.
- Fixed a bug: If you used in a table name characters whose code is > 127, in `DROP TABLE InnoDB` could assert on line 155 of `pars0sym.c`.
- Compilation from source now provides a working version both on HP-UX-11 and HP-UX-10.20. The source of 4.0.2 worked only on 11, and the source of 3.23.52 only on 10.20.

- Fixed a bug: If compiled on 64-bit Solaris, InnoDB produced a bus error at startup.

## D.9.32. MySQL/InnoDB-3.23.52, August 16, 2002

- The feature set of 3.23 is frozen from this version on. New features go the 4.0 branch, and only bugfixes are made to the 3.23 branch.
- Many CPU-bound join queries now run faster. On Windows also many other CPU-bound queries run faster.
- A new SQL command `SHOW INNODB STATUS` returns the output of the InnoDB Monitor to the client. The InnoDB Monitor now prints detailed information on the latest detected deadlock.
- InnoDB made the SQL query optimizer to avoid too much index-only range scans and choose full table scans instead. This is now fixed.
- `BEGIN` and `COMMIT` are now added in the binary log around transactions. The MySQL replication now respects transaction borders: a user no longer sees half transactions in replication slaves.
- A replication slave now prints in crash recovery the last master binary log position it was able to recover to.
- A new setting `innodb_flush_log_at_trx_commit=2` makes InnoDB to write the log to the operating system file cache at each commit. This is almost as fast as the setting `innodb_flush_log_at_trx_commit=0`, and the setting 2 also has the nice feature that in a crash where the operating system does not crash, no committed transaction is lost. If the operating system crashes or there is a power outage, then the setting 2 is no safer than the setting 0.
- Added checksum fields to log blocks.
- `SET FOREIGN_KEY_CHECKS=0` helps in importing tables in an arbitrary order which does not respect the foreign key rules.
- `SET UNIQUE_CHECKS=0` speeds up table imports into InnoDB if you have `UNIQUE` constraints on secondary indexes. This flag should be used only if you are certain that the input records contain no `UNIQUE` constraint violations.
- `SHOW TABLE STATUS` now lists also possible `ON DELETE CASCADE` or `ON DELETE SET NULL` in the comment field of the table.
- When `CHECK TABLE` is run on any InnoDB type table, it now checks also the adaptive hash index for all tables.
- If you defined `ON DELETE CASCADE` or `SET NULL` and updated the referenced key in the parent row, InnoDB deleted or updated the child row. This is now changed to conform to standard SQL: you get the error 'Cannot delete parent row'.
- Improved the auto-increment algorithm: now the first insert or `SHOW TABLE STATUS` initializes the auto-increment counter for the table. This removes almost all surprising deadlocks caused by `SHOW TABLE STATUS`.
- Aligned some buffers used in reading and writing to data files. This allows using unbuffered raw devices as data files in Linux.
- Fixed a bug: If you updated the primary key of a table so that only the case of characters changed, that could cause assertion failures, mostly in `page0page.ic` line 515.
- Fixed a bug: If you delete or update a row referenced in a foreign key constraint and the foreign key check has to wait for a lock, then the check may report an erroneous result. This affects also the `ON DELETE...` operation.

- Fixed a bug: A deadlock or a lock wait timeout error in InnoDB causes InnoDB to roll back the whole transaction, but MySQL could still write the earlier SQL statements to the binary log, even though InnoDB rolled them back. This could, for example, cause replicated databases to get out-of-sync.
- Fixed a bug: If the database happened to crash in the middle of a commit, then the recovery might leak tablespace pages.
- Fixed a bug: If you specified a non-latin1 character set in my.cnf, then, in contrary to what is stated in the manual, in a foreign key constraint a string type column had to have the same length specification in the referencing table and the referenced table.
- Fixed a bug: DROP TABLE or DROP DATABASE could fail if there simultaneously was a CREATE TABLE running.
- Fixed a bug: If you configured the buffer pool bigger than 2GB in a 32-bit computer, InnoDB would assert in buf0buf.ic line 214.
- Fixed a bug: on 64-bit computers updating rows which contained the SQL NULL in some column could cause the undo log and the ordinary log to become corrupt.
- Fixed a bug: innodb\_log\_monitor caused a hang if it suppressed lock prints for a page.
- Fixed a bug: in the HP-UX-10.20 version mutexes would leak and cause race conditions and crashes in any part of InnoDB code.
- Fixed a bug: If you ran in the AUTOCOMMIT mode, executed a SELECT, and immediately after that a RENAME TABLE, then RENAME would fail and MySQL would complain about error 1192.
- Fixed a bug: If compiled on 64-bit Solaris, InnoDB produced a bus error at startup.

### **D.9.33. MySQL/InnoDB-4.0.2, July 10, 2002**

- InnoDB is essentially the same as InnoDB-3.23.51.
- If no innodb\_data\_file\_path is specified, InnoDB at the database creation now creates a 10MB auto-extending data file ibdata1 to the datadir of MySQL. In 4.0.1 the file was 64MB and not auto-extending.

### **D.9.34. MySQL/InnoDB-3.23.51, June 12, 2002**

- Fixed a bug: a join could result in a seg fault in copying of a BLOB or TEXT column if some of the BLOB or TEXT columns in the table contained SQL NULL values.
- Fixed a bug: If you added self-referential foreign key constraints with ON DELETE CASCADE to tables and a row deletion caused InnoDB to attempt the deletion of the same row twice because of a cascading delete, then you got an assertion failure.
- Fixed a bug: If you use MySQL 'user level locks' and close a connection, then InnoDB may assert in ha\_innobase.cc, line 302.

### **D.9.35. MySQL/InnoDB-3.23.50, April 23, 2002**

- InnoDB now supports an auto-extending last data file. You do not need to preallocate the whole data file at the database startup.

- Made several changes to facilitate the use of the InnoDB Hot Backup tool. It is a separate non-free tool you can use to take online backups of your database without shutting down the server or setting any locks.
- If you want to run the InnoDB Hot Backup tool on an auto-extending data file you have to upgrade it to version ibbackup-0.35.
- The log scan phase in crash recovery now runs much faster.
- Starting from this server version, the hot backup tool truncates unused ends in the backup InnoDB data files.
- To allow the hot backup tool to work, on Windows we no longer use unbuffered I/O or native async I/O; instead we use the same simulated async I/O as on Unix.
- You can now define the ON DELETE CASCADE or ON DELETE SET NULL clause on foreign keys.
- FOREIGN KEY constraints now survive ALTER TABLE and CREATE INDEX.
- We suppress the FOREIGN KEY check if any of the column values in the foreign key or referenced key to be checked is the SQL NULL. This is compatible with Oracle, for example.
- SHOW CREATE TABLE now lists also foreign key constraints. Also mysqldump no longer forgets about foreign keys in table definitions.
- You can now add a new foreign key constraint with ALTER TABLE ... ADD CONSTRAINT FOREIGN KEY (...) REFERENCES ... (...).
- FOREIGN KEY definitions now allow backticks around table and column names.
- MySQL command SET TRANSACTION ISOLATION LEVEL ... has now the following effect on InnoDB tables: If a transaction is defined as SERIALIZABLE then InnoDB conceptually adds LOCK IN SHARE MODE to all consistent reads. If a transaction is defined to have any other isolation level, then InnoDB obeys its default locking strategy which is REPEATABLE READ.
- SHOW TABLE STATUS no longer sets an x-lock at the end of an auto-increment index if the auto-increment counter has been initialized. This removes in almost all cases the surprising deadlocks caused by SHOW TABLE STATUS.
- Fixed a bug: in a CREATE TABLE statement the string 'foreign' followed by a non-space character confused the FOREIGN KEY parser and caused table creation to fail with errno 150.

## D.9.36. MySQL/InnoDB-3.23.49, February 17, 2002

- Fixed a bug: If you called DROP DATABASE for a database on which there simultaneously were running queries, the MySQL server could crash or hang. Crashes fixed, but a full fix has to wait some changes in the MySQL layer of code.
- Fixed a bug: on Windows one had to put the database name in lowercase for DROP DATABASE to work. Fixed in 3.23.49: case no longer matters on Windows. On Unix, the database name remains case sensitive.
- Fixed a bug: If one defined a non-latin1 character set as the default character set, then definition of foreign key constraints could fail in an assertion failure in dict0crea.c, reporting an internal error 17.

## D.9.37. MySQL/InnoDB-3.23.48, February 9, 2002

- Tuned the SQL optimizer to favor more often index searches over table scans.
- Fixed a performance problem when several large SELECT queries are run concurrently on a multiprocessor Linux computer. Large CPU-bound SELECT queries now also generally run faster on all platforms.
- If MySQL binary logging is used, InnoDB now prints after crash recovery the latest MySQL binary log file name and the position in that file (= byte offset) InnoDB was able to recover to. This is useful, for example, when resynchronizing a master and a slave database in replication.
- Added better error messages to help in installation problems.
- One can now recover also MySQL temporary tables which have become orphaned inside the InnoDB tablespace.
- InnoDB now prevents a FOREIGN KEY declaration where the signedness is not the same in the referencing and referenced integer columns.
- Fixed a bug: calling SHOW CREATE TABLE or SHOW TABLE STATUS could cause memory corruption and make **mysqld** to crash. Especially at risk was mysqldump, because it calls frequently SHOW CREATE TABLE.
- Fixed a bug: If on Unix you did an ALTER TABLE to an InnoDB table and simultaneously did queries to it, **mysqld** could crash with an assertion failure in row0row.c, line 474.
- Fixed a bug: If inserts to several tables containing an auto-inc column were wrapped inside one LOCK TABLES, InnoDB asserted in lock0lock.c.
- In 3.23.47 we allowed several NULLS in a UNIQUE secondary index. But CHECK TABLE was not relaxed: it reports the table as corrupt. CHECK TABLE no longer complains in this situation.
- Fixed a bug: on Sparc and other high-endian processors SHOW VARIABLES showed innodb\_flush\_log\_at\_trx\_commit and other boolean-valued startup parameters always OFF even if they were switched on.
- Fixed a bug: If you ran mysqld-max-nt as a service on Windows NT/2000, the service shutdown did not always wait long enough for the InnoDB shutdown to finish.

## D.9.38. MySQL/InnoDB-3.23.47, December 28, 2001

- Recovery happens now faster, especially in a lightly loaded system, because background checkpointing has been made more frequent.
- InnoDB allows now several similar key values in a UNIQUE secondary index if those values contain SQL NULLS. Thus the convention is now the same as in MyISAM tables.
- InnoDB gives a better row count estimate for a table which contains BLOBs.
- In a FOREIGN KEY constraint InnoDB is now case-insensitive to column names, and in Windows also to table names.
- InnoDB allows a FOREIGN KEY column of CHAR type to refer to a column of VARCHAR type, and vice versa. MySQL silently changes the type of some columns between CHAR and VARCHAR, and these silent changes do not hinder FOREIGN KEY declaration any more.
- Recovery has been made more resilient to corruption of log files.
- Unnecessary statistics calculation has been removed from queries which generate a temporary table. Some ORDER BY and DISTINCT queries now run much faster.

- MySQL now knows that the table scan of an InnoDB table is done through the primary key. This saves a sort in some ORDER BY queries.
- The maximum key length of InnoDB tables is again restricted to 500 bytes. The MySQL interpreter is not able to handle longer keys.
- The default value of innodb\_lock\_wait\_timeout was changed from infinite to 50 seconds, the default value of innodb\_file\_io\_threads from 9 to 4.

### **D.9.39. MySQL/InnoDB-4.0.1, December 23, 2001**

- InnoDB is the same as in 3.23.47.
- In 4.0.0 the MySQL interpreter did not know the syntax LOCK IN SHARE MODE. This has been fixed.
- In 4.0.0 multiple-table delete did not work for transactional tables. This has been fixed.

### **D.9.40. MySQL/InnoDB-3.23.46, November 30, 2001**

- This is the same as 3.23.45.

### **D.9.41. MySQL/InnoDB-3.23.45, November 23, 2001**

- This is a bugfix release.
- In versions 3.23.42-.44 when creating a table on Windows, you have to use lowercase letters in the database name to be able to access the table. Fixed in 3.23.45.
- InnoDB now flushes stdout and stderr every 10 seconds: If these are redirected to files, the file contents can be better viewed with an editor.
- Fixed an assertion failure in .44, in trx0trx.c, line 178 when you drop a table which has the .frm file but does not exist inside InnoDB.
- Fixed a bug in the insert buffer. The insert buffer tree could get into an inconsistent state, causing a crash, and also crashing the recovery. This bug could appear especially in large table imports or alterations.
- Fixed a bug in recovery: InnoDB could go into an infinite loop constantly printing a warning message that it cannot find free blocks from the buffer pool.
- Fixed a bug: when you created a temporary table of the InnoDB type, and then used ALTER TABLE to it, the MySQL server could crash.
- Prevented creation of MySQL system tables 'mysql.user', 'mysql.host', or 'mysql.db', in the InnoDB type.
- Fixed a bug which can cause an assertion failure in 3.23.44 in srv0srv.c, line 1728.

### **D.9.42. MySQL/InnoDB-3.23.44, November 2, 2001**

- You can define foreign key constraints on InnoDB tables. An example: FOREIGN KEY (col1)

REFERENCES table2(col2).

- You can create data files larger than 4GB in those filesystems that allow it.
- Improved InnoDB monitors, including a new `innodb_table_monitor` which allows you to print the contents of the InnoDB internal data dictionary.
- DROP DATABASE now works also for InnoDB tables.
- Accent characters in the default character set latin1 are ordered according to the MySQL ordering.

NOTE: If you are using latin1 and have inserted characters whose code is > 127 to an indexed CHAR column, you should run CHECK TABLE on your table when you upgrade to 3.23.43, and drop and reimport the table if CHECK TABLE reports an error!

- InnoDB calculates better table cardinality estimates.
- Change in deadlock resolution: in .43 a deadlock rolls back only the SQL statement, in .44 it rolls back the whole transaction.
- Deadlock, lock wait timeout, and foreign key constraint violations (no parent row, child rows exist) now return native MySQL error codes 1213, 1205, 1216, 1217, respectively.
- A new my.cnf parameter `innodb_thread_concurrency` helps in performance tuning in high concurrency environments.
- A new my.cnf option `innodb_force_recovery` helps you in dumping tables from a corrupted database.
- A new my.cnf option `innodb_fast_shutdown` speeds up shutdown. Normally InnoDB does a full purge and an insert buffer merge at shutdown.
- Raised maximum key length to 7000 bytes from a previous limit of 500 bytes.
- Fixed a bug in replication of auto-inc columns with multiline inserts.
- Fixed a bug when the case of letters changes in an update of an indexed secondary column.
- Fixed a hang when there are more than 24 data files.
- Fixed a crash when MAX(col) is selected from an empty table, and col is a not the first column in a multi-column index.
- Fixed a bug in purge which could cause crashes.

### D.9.43. MySQL/InnoDB-3.23.43, October 4, 2001

- This is essentially the same as InnoDB-3.23.42.

### D.9.44. MySQL/InnoDB-3.23.42, September 9, 2001

- Fixed a bug which corrupted the table if the primary key of a > 8000-byte row was updated.
- There are now 3 types of InnoDB Monitors: `innodb_monitor`, `innodb_lock_monitor`, and `innodb_tablespace_monitor`. `innodb_monitor` now prints also buffer pool hit rate and the total number of rows inserted, updated, deleted, read.
- Fixed a bug in RENAME TABLE.

- Fixed a bug in replication with an auto-increment column.

## D.9.45. MySQL/InnoDB-3.23.41, August 13, 2001

- Support for < 4GB rows. The previous limit was 8000 bytes.
- Use the doublewrite file flush method.
- Raw disk partitions supported as data files.
- InnoDB Monitor.
- Several hang bugs fixed and an ORDER BY bug ("Sort aborted") fixed.

## D.9.46. MySQL/InnoDB-3.23.40, July 16, 2001

- Only a few rare bugs fixed.

## D.9.47. MySQL/InnoDB-3.23.39, June 13, 2001

- CHECK TABLE now works for InnoDB tables.
- A new my.cnf parameter innodb\_unix\_file\_flush\_method introduced. It can be used to tune disk write performance.
- An auto-increment column now gets new values past the transaction mechanism. This saves CPU time and eliminates transaction deadlocks in new value assignment.
- Several bugfixes, most notably the rollback bug in 3.23.38.

## D.9.48. MySQL/InnoDB-3.23.38, May 12, 2001

- The new syntax SELECT ... LOCK IN SHARE MODE is introduced.
- InnoDB now calls fsync() after every disk write and calculates a checksum for every database page it writes or reads, which reveals disk defects.
- Several bugfixes.

# D.10. MySQL Cluster Change History

## D.10.1. MySQL Cluster-4.1.12

Functionality added or changed:

Bugs fixed:

- Creating a table did not work for a cluster with 6 nodes. (Bug #8928 [<http://bugs.mysql.com/8928>]) Databases with 1, 2, 4, 8, ... (2<sup>n</sup> nodes) did not have the problem. After a rolling upgrade, restart each node manually by restarting it with the `--initial`

option. Otherwise, use dump and restore after an upgrade.

## D.10.2. MySQL Cluster-4.1.11 (01 Apr 2005)

Functionality added or changed:

Bugs fixed:

- (Bug #9435 [<http://bugs.mysql.com/9435>]) TIMESTAMP columns don't update
- (Bug #8753 [<http://bugs.mysql.com/8753>]) Invalid schema object version after dropping index (crash fixed, currently retry required)
- (Bug #8557 [<http://bugs.mysql.com/8557>]) ndbd does not get same nodeid on restart
- (Bug #8556 [<http://bugs.mysql.com/8556>]) corrupt ndb\_mgm show printout for certain configurations
- (Bug #8167 [<http://bugs.mysql.com/8167>]) cluster shared memory and mysqld signal usage clash

## D.10.3. MySQL Cluster-4.1.10 (12 Feb 2005)

Bugs fixed:

- (Bug #8284 [<http://bugs.mysql.com/8284>]) Out of fragment memory in DBACC
- (Bug #8262 [<http://bugs.mysql.com/8262>]) Node crash due to bug in DBLQH
- (Bug #8208 [<http://bugs.mysql.com/8208>]) node restart fails on Aix 5.2
- (Bug #8167 [<http://bugs.mysql.com/8167>]) cluster shared memory and mysqld signal usage clash
- (Bug #8101 [<http://bugs.mysql.com/8101>]) unique index and error 4209 while selecting
- (Bug #8070 [<http://bugs.mysql.com/8070>]) (Bug #7937 [<http://bugs.mysql.com/7937>]) (Bug #6716 [<http://bugs.mysql.com/6716>]) various ndb\_restore core dumps on HP-UX
- (Bug #8010 [<http://bugs.mysql.com/8010>]) 4006 forces MySQL Node Restart
- (Bug #7928 [<http://bugs.mysql.com/7928>]) out of connection objects
- (Bug #7898 [<http://bugs.mysql.com/7898>]) mysqld crash with ndb (solaris)
- (Bug #7864 [<http://bugs.mysql.com/7864>]) Not possible to have more than 4.5G data memory

## D.10.4. MySQL Cluster-4.1.9 (13 Jan 2005)

Functionality added or changed:

- New implementation of shared memory transporter.
- Cluster automatically configures shared memory transporter if possible.
- Cluster prioritizes usage of transporters with shared memory and localhost TCP

- Added switches to control the above functions, `ndb-shm` and `ndb-optimized-node-selection`.

Bugs fixed:

- (Bug #7805 [<http://bugs.mysql.com/7805>]) `config.ini` parsing error
- (Bug #7798 [<http://bugs.mysql.com/7798>]) Running range scan after alter table in different thread causes node failure
- (Bug #7761 [<http://bugs.mysql.com/7761>]) Alter table does not autocommit
- (Bug #7725 [<http://bugs.mysql.com/7725>]) Indexed DATETIME Columns Return Random Results
- (Bug #7660 [<http://bugs.mysql.com/7660>]) START BACKUP does not increment BACKUP-ID (Big Endian machines)
- (Bug #7593 [<http://bugs.mysql.com/7593>]) Cannot Create A Large NDB Data Warehouse
- (Bug #7480 [<http://bugs.mysql.com/7480>]) Mysqld crash in `ha_ndbcluster` using Query Browser
- (Bug #7470 [<http://bugs.mysql.com/7470>]) shared memory transporter does not connect
- (Bug #7396 [<http://bugs.mysql.com/7396>]) Primary Key not working in NDB MySQL Clustered table (solaris)
- (Bug #7379 [<http://bugs.mysql.com/7379>]) `ndb restore` fails to handle blobs and multiple databases
- (Bug #7346 [<http://bugs.mysql.com/7346>]) `ndb_restore` enters infinite loop
- (Bug #7340 [<http://bugs.mysql.com/7340>]) Problem for inserting data into the Text field on utf8
- (Bug #7124 [<http://bugs.mysql.com/7124>]) `ndb_mgmd` is aborted on startup when using SHM connection

## D.10.5. MySQL Cluster-4.1.8 (14 Dec 2004)

Functionality added or changed:

- Default port for `ndb_mgmd` was changed to 1186 (from 2200) as this port number was officially assigned to MySQL Cluster by IANA.
- New command in `ndb_mgm`, `PURGE STALE SESSIONS`, as a workaround for cases where nodes fail to allocate a node id even if it is free to use.
- New command in `ndb_mgm`, `CONNECT`.
- The `ndb` executables have been changed to make use of the regular MySQL command line option parsing features. See Section 16.5.5, “Command Options for MySQL Cluster Processes” for notes on changes.
- As bonus of the above you can now specify all command line options in `my.cnf` using the executable names as sections, i.e. `[ndbd]`, `[ndb_mgmd]`, `[ndb_mgm]`, `[ndb_restore]` etc.

```
[ndbd]
ndb-connectstring=myhost.domain.com:1234
[ndb_mgm]
ndb-connectstring=myhost.domain.com:1234
```

- Added use of section `[mysql_cluster]` in `my.cnf`. All cluster executables, including `mysqld`, parse this section. Convenient place to put e.g. `ndb-connectstring` so that it only needs to be specified once.
- Added cluster log info events on allocation and deallocation of nodeid's.
- Added cluster log info events on connection refuse as a result of version mismatch.
- Extended `connectstring` syntax to allow for leaving the port number out. E.g. `ndb-connectstring|connect-string=myhost1,myhost2,myhost3` is a valid `connectstring` and `connect` occurs on default port 1186.
- Clear text `ndb` error messages provided also for error codes that are mapped to corresponding `mysql` error codes, by executing `SHOW WARNINGS` after an error has occurred which relates to the `ndb` storage engine.
- Significant performance improvements done for read performance, especially for blobs.
- Added some variables for performance tuning, `ndb_force_send` and `ndb_use_exact_count`. Do show variables like `'ndb%'` in `mysql` client for listing. Use `set` command to alter variables.
- Added variables to set some options, `ndb_use_transactions` and `ndb_autoincrement_prefetch_sz`.

### Bugs fixed:

- (Bug #7303 [<http://bugs.mysql.com/7303>]) `ndb_mgm`: Trying to set `CLUSTERLOG` for a specific node id core dumps
- (Bug #7193 [<http://bugs.mysql.com/7193>]) `start backup` gives false error printout
- (Bug #7153 [<http://bugs.mysql.com/7153>]) Cluster nodes don't report error on endianness mismatch
- (Bug #7152 [<http://bugs.mysql.com/7152>]) `ndb_mgmd` segfaults on incorrect `HostName` in configuration
- (Bug #7104 [<http://bugs.mysql.com/7104>]) `clusterlog` filtering and level setting broken
- (Bug #6995 [<http://bugs.mysql.com/6995>]) `ndb_recover` on `varchar` fields results in changing case of data
- (Bug #6919 [<http://bugs.mysql.com/6919>]) `all status` only shows 2 nodes on a 8-node cluster
- (Bug #6871 [<http://bugs.mysql.com/6871>]) `DBD execute failed: Got error 897 'Unknown error code'` from `ndbcluster`
- (Bug #6794 [<http://bugs.mysql.com/6794>]) Wrong outcome of update operation of `ndb` table
- (Bug #6791 [<http://bugs.mysql.com/6791>]) Segmentation fault when `config.ini` is not correctly set
- (Bug #6775 [<http://bugs.mysql.com/6775>]) failure in `acc` when running many `mysql` clients
- (Bug #6696 [<http://bugs.mysql.com/6696>]) `ndb_mgm` command line options inconsistent with behavior
- (Bug #6684 [<http://bugs.mysql.com/6684>]) `ndb_restore` doesn't give error messages if improper

command given

- (Bug #6677 [<http://bugs.mysql.com/6677>]) `ndb_mgm` can crash on "ALL CLUSTERLOG"
- (Bug #6538 [<http://bugs.mysql.com/6538>]) Error code returned when `select max()` on empty table with index
- (Bug #6451 [<http://bugs.mysql.com/6451>]) failing create table gives "ghost" tables which are impossible to remove
- (Bug #6435 [<http://bugs.mysql.com/6435>]) strange behavior of left join
- (Bug #6426 [<http://bugs.mysql.com/6426>]) update with long pk fails
- (Bug #6398 [<http://bugs.mysql.com/6398>]) update of primary key fails
- (Bug #6354 [<http://bugs.mysql.com/6354>]) mysql does not complain about `--ndbcluster` option when NDB is not compiled in
- (Bug #6331 [<http://bugs.mysql.com/6331>]) `INSERT IGNORE .. SELECT` breaks subsequent inserts
- (Bug #6288 [<http://bugs.mysql.com/6288>]) cluster nodes crash on data import
- (Bug #6031 [<http://bugs.mysql.com/6031>]) To drop database you have to execute `DROP DATABASE` command twice
- (Bug #6020 [<http://bugs.mysql.com/6020>]) `LOCK TABLE + delete` returns error 208
- (Bug #6018 [<http://bugs.mysql.com/6018>]) `REPLACE` does not work for BLOBs + NDB
- (Bug #6016 [<http://bugs.mysql.com/6016>]) Strange crash with blobs + different DATABASES
- (Bug #5973 [<http://bugs.mysql.com/5973>]) `ndb` table belonging to different database shows up in `show tables`
- (Bug #5872 [<http://bugs.mysql.com/5872>]) `ALTER TABLE` with blob from `ndb` table to `myisam` fails
- (Bug #5844 [<http://bugs.mysql.com/5844>]) Failing `mysql-test-run` leaves stray NDB processes behind
- (Bug #5824 [<http://bugs.mysql.com/5824>]) `HELP` text messed up in `ndb_mgm`
- (Bug #5786 [<http://bugs.mysql.com/5786>]) Duplicate key error after restore
- (Bug #5785 [<http://bugs.mysql.com/5785>]) lock timeout during concurrent update
- (Bug #5782 [<http://bugs.mysql.com/5782>]) Unknown error when using `LIMIT` with `ndb` table
- (Bug #5756 [<http://bugs.mysql.com/5756>]) `RESTART` node from `ndb_mgm` fails
- A few more not reported bugs fixed

## D.10.6. MySQL Cluster-4.1.7 (23 Oct 2004)

Functionality added or changed:

- Optimization 1: Improved performance on index scans. Measured 30% performance increase on query which do large amounts of index scans.
- Optimization 2: Improved performance on primary key lookups. Around double performance for

autocommitted primary key lookups.

- Optimization 3: Improved performance when using blobs by avoiding usage of exclusive locks for blobs.

Bugs fixed:

- A few bugs fixed.

## D.10.7. MySQL Cluster-4.1.6 (10 Oct 2004)

Functionality added or changed:

- Limited character set support for storage engine NDBCLUSTER:

| Char set | Collation         |
|----------|-------------------|
| big5     | big5_chinese_ci   |
|          | big5_bin          |
| binary   | binary            |
|          |                   |
| euckr    | euckr_korean_ci   |
|          | euckr_bin         |
| gb2312   | gb2312_chinese_ci |
|          | gb2312_bin        |
| gbk      | gbk_chinese_ci    |
|          | gbk_bin           |
| latin1   | latin1_swedish_ci |
|          | latin1_bin        |
| sjis     | sjis_japanese_ci  |
|          | sjis_bin          |
| tis620   | tis620_bin        |
| ucs2     | ucs2_general_ci   |
|          | ucs2_bin          |
| ujis     | ujis_japanese_ci  |
|          | ujis_bin          |
| utf8     | utf8_general_ci   |
|          | utf8_bin          |

- The SCI Transporter has been brought up-to-date with all changes and now works and has been documented as well.
- Optimizations when several clients to a MySQL Server access ndb tables.
- Added more checks and warnings for erroneous and inappropriate cluster configurations.
- SHOW TABLES now directly shows ndb tables created on a different mysql server, i.e. without a prior table access.
- Enhanced support for starting MySQL Server independently of nbdb and ndb\_mgmd.
- Clear text ndb error messages provided by executing SHOW WARNINGS after an error has oc-

cured which relates to the ndb storage engine.

Bugs fixed:

- Quite a few bugs fixed.

## D.10.8. MySQL Cluster-4.1.5 (16 Sep 2004)

Functionality added or changed:

- Many queries in MySQL Cluster are executed as range scans or full table scans. All queries that don't use a unique hash index or the primary hash index use this access method. In a distributed system it is crucial that batching is properly performed.

In previous versions, the batch size was fixed to 16 per data node. In this version it is configurable per MySQL Server. So for queries using lots of large scans it is appropriate to set this parameter rather large and for queries using many small scans only fetching a small amount of records it is appropriate to set it low.

The performance of queries can easily change as much as 40% based on how this variable is set.

In future versions more logic will be implemented for assessing the batch size on a per-query basis. Thus, the semantics of the new configuration variable `ScanBatchSize` are likely to change.

- The fixed size overhead of the ndbd process has been greatly decreased. This is also true for the overhead per operation record as well as overhead per table and index.

A number of new configuration variables have been introduced to enable configuration of system buffers. Configuration variables for specifying the numbers of tables, unique hash indexes, and ordered indexes have also been introduced.

New configuration variables: `MaxNoOfOrderedIndexes`, `MaxNoOfUniqueHashIndexes`

Configuration variables no longer used: `MaxNoOfIndexes` (split into the two above).

- In previous versions `ALTER TABLE`, `TRUNCATE TABLE`, and `LOAD DATA` were performed as one big transaction. In this version, all of these statements are automatically separated into several distinct transactions.

This removes the limitation that one could not change very large tables due to the `MaxNoOfConcurrentOperations` parameter.

- MySQL Cluster's online backup feature now backs up indexes so that both data and indexes are restored.
- In previous versions it was not possible to use `NULL` in indexes. This is now possible for all supported index types.
- Much work has been put onto making `AUTO_INCREMENT` features work as for other table handlers. Autoincrements as a partial key is still only supported by `MyISAM`.
- In earlier versions, `mysqld` would crash if the cluster wasn't started with the `--ndbcluster` option. Now `mysqld` handles cluster crashes and starts without crashing.
- The `-i` option for initial startup of `ndbd` has been removed. Initial startup still can be specified by using the `--initial` option. The reason for this is to ensure that it is clear what takes place when using `--initial`: this option completely removes all data from the disk and should only

be used at initial start, in certain software upgrade cases, and in some cases as a workaround when nodes cannot be restarted successfully.

- The management client (**ndb\_mgm**) now has additional commands and more information is printed for some commands such as `show`.
- In previous versions, the files were called `ndb_0..` when it wasn't possible to allocate a node ID when starting the node. To ensure that files are not so easily overwritten, these files are now named `ndb_pid..`, where `pid` is the process ID assigned by the OS.
- The default parameters have changed for **ndb\_mgmd** and **ndbd**. In particular, they are now started as daemons by default. The `-n` option has been removed since it could cause confusion as to its meaning (nstart or nodaemon).
- In the configuration file, you can now use `[NDBD]` as an alias for `[DB]`, `[MYSQLD]` as an alias for `[API]`, and `[NDB_MGMD]` as an alias for `[MGM]`. **Note:** In fact, `[NDBD]`, `[MYSQLD]`, and `[NDB_MGMD]` are now the preferred designations, although the older ones will continue to be supported for some time to come in order to maintain backwards compatibility.
- Many more checks for consistency in configuration have been introduced to in order to provide quicker feedback on configuration errors.
- In the connect string, it is now possible to use both `;` and `,` as the separator between entries. Thus, `"nodeid=2,host=localhost:2200"` is equivalent to `"nodeid=2;host=localhost:2200"`.

In the configuration file, it is also possible to use `:` or `=` for assignment values. For example, `MaxNoOfOrderedIndexes : 128` and `MaxNoOfOrderedIndexes = 128` are equivalent expressions.

- The configuration variable names are now case insensitive, so `MaxNoOfOrderedIndexes : 128` is equivalent to `MAXNOOFORDEREDINDEXES = 128`.
- It is possible now to set the backup directory separately from the `FileSystemPath` by using the `BackupDir` configuration variable.

Log files and trace files can now be placed in any directory by setting the `DataDir` configuration variable.

`FileSystemPath` is no longer mandatory and defaults to `DataDir`.

- Queries involving tables from different databases are now supported.
- It is now possible to update the primary key.
- The performance of ordered indexes has been greatly improved, particularly the maintenance of indexes on updates, inserts and deletes.

Bugs fixed:

- Quite a few bugs fixed.

## D.10.9. MySQL Cluster-4.1.4 (31 Aug 2004)

Functionality added or changed:

- The names of the log files and trace files created by the **ndbd** and **ndb\_mgmd** processes have changed.
- Support for the many BLOB data types was introduced in this version.

Bugs fixed:

- Quite a few bugs were fixed in the 4.1.4 release.

## D.10.10. MySQL Cluster-5.0.1 (27 Jul 2004)

Functionality added or changed:

- This was the first MySQL Cluster release in the 5.0 series. As nearly all attention was still focused on getting 4.1 stable, it is not recommended to use MySQL 5.0.1 for MySQL Cluster.

Bugs fixed:

- 

## D.10.11. MySQL Cluster-4.1.3 (28 Jun 2004)

Functionality added or changed:

- This was the first MySQL Cluster release so all functionality was new.

Bugs fixed:

- Various bugs fixed in the development process leading up to 4.1.3.

## D.11. Changes in MyODBC

### D.11.1. Changes in MyODBC 3.51.12

Functionality added or changed:

- 

Bugs fixed:

- `SQLColumns()` returned no information for tables that had a column named using a reserved word. (Bug #9539 [<http://bugs.mysql.com/9539>])

### D.11.2. Changes in MyODBC 3.51.11

Functionality added or changed: No changes.

Bugs fixed:

- `mysql_list_dbcolumns()` and `insert_fields()` were retrieving all rows from a table. Fixed the queries generated by these functions to return no rows. (Bug #8198 [<http://bugs.mysql.com/8198>])

- `SQLGetTypeInfo()` returned `tinyblob` for `SQL_VARBINARY` and nothing for `SQL_BINARY`. Fixed to return `varbinary` for `SQL_VARBINARY`, `binary` for `SQL_BINARY`, and `longblob` for `SQL_LONGVARBINARY`. (Bug #8138 [<http://bugs.mysql.com/8138>])

---

# Appendix E. Porting to Other Systems

This appendix helps you port MySQL to other operating systems. Do check the list of currently supported operating systems first. See Section 2.1.1, “Operating Systems Supported by MySQL”. If you have created a new port of MySQL, please let us know so that we can list it here and on our Web site (<http://www.mysql.com/>), recommending it to other users.

Note: If you create a new port of MySQL, you are free to copy and distribute it under the GPL license, but it does not make you a copyright holder of MySQL.

A working POSIX thread library is needed for the server. On Solaris 2.5 we use Sun PThreads (the native thread support in 2.4 and earlier versions is not good enough), on Linux we use LinuxThreads by Xavier Leroy, <[Xavier.Leroy@inria.fr](mailto:Xavier.Leroy@inria.fr)>.

The hard part of porting to a new Unix variant without good native thread support is probably to port MIT-pthreads. See [mit-pthreads/README](http://mit-pthreads.org/README) and Programming POSIX Threads (<http://www.humanfactor.com/pthreads/>).

Up to MySQL 4.0.2, the MySQL distribution included a patched version of Chris Provenzano's Pthreads from MIT (see the MIT Pthreads Web page at <http://www.mit.edu/afs/sipb/project/pthreads/> and a programming introduction at [http://www.mit.edu:8001/people/proven/IAP\\_2000/](http://www.mit.edu:8001/people/proven/IAP_2000/)). These can be used for some operating systems that do not have POSIX threads. See Section 2.8.5, “MIT-pthreads Notes”.

It is also possible to use another user level thread package named FSU Pthreads (see <http://moss.csc.ncsu.edu/~mueller/pthreads/>). This implementation is being used for the SCO port.

See the `thr_lock.c` and `thr_alarm.c` programs in the `mysys` directory for some tests/examples of these problems.

Both the server and the client need a working C++ compiler. We use **gcc** on many platforms. Other compilers that are known to work are SPARCworks, Sun Forte, Irix **cc**, HP-UX **aCC**, IBM AIX **x1C\_r**), Intel **ecc/icc** and Compaq **cxx**).

To compile only the client use **`./configure --without-server`**.

There is currently no support for only compiling the server, nor is it likely to be added unless someone has a good reason for it.

If you want/need to change any Makefile or the configure script you also need GNU Automake and Autoconf. See Section 2.8.3, “Installing from the Development Source Tree”.

All steps needed to remake everything from the most basic files.

```
/bin/rm */.deps/*.P
/bin/rm -f config.cache
aclocal
autoheader
aclocal
automake
autoconf
./configure --with-debug=full --prefix='your installation directory'

The makefiles generated above need GNU make 3.75 or newer.
(called gmake below)
gmake clean all install init-db
```

If you run into problems with a new port, you may have to do some debugging of MySQL! See Section E.1, “Debugging a MySQL Server”.

**Note:** Before you start debugging **mysqld**, first get the test programs `mysys/thr_alarm` and `mysys/thr_lock` to work. This ensures that your thread installation has even a remote chance to

work!

## E.1. Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run **mysqld** with the `--skip-new` (which disables all new, potentially unsafe functionality) or with `--safe-mode` which disables a lot of optimization that may cause problems. See Section A.4.2, “What to Do If MySQL Keeps Crashing”.

If **mysqld** doesn't want to start, you should verify that you don't have any `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with **mysqld --print-defaults** and avoid using them by starting with **mysqld --no-defaults ...**

If **mysqld** starts to eat up CPU or memory or if it “hangs,” you can use **mysqladmin processlist status** to find out if someone is executing a query that takes a long time. It may be a good idea to run **mysqladmin -i10 processlist status** in some window if you are experiencing performance problems or problems when new clients can't connect.

The command **mysqladmin debug** dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you haven't compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or **myisamchk**. See Chapter 5, *Database Administration*. You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See Section 2.12, “Operating System-Specific Notes”.

### E.1.1. Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `--with-debug` or the `--with-debug=full` option. You can check whether MySQL was compiled with debugging by doing: **mysqld --help**. If the `--debug` flag is listed with the options then you have debugging enabled. **mysqladmin ver** also lists the **mysqld** version as **mysql ... --debug** in this case.

If you are using **gcc** or **egcs**, the recommended **configure** line is:

```
CC=gcc CFLAGS="-O2" CXX=gcc CXXFLAGS="-O2 -felide-constructors \
-fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql \
--with-debug --with-extra-charsets=complex
```

This avoids problems with the `libstdc++` library and with C++ exceptions (many compilers have problems with C++ exceptions in threaded code) and compile a MySQL version with support for all character sets.

If you suspect a memory overrun error, you can configure MySQL with `--with-debug=full`, which installs a memory allocation (`SAFEMALLOC`) checker. However, running with `SAFEMALLOC` is quite slow, so if you get performance problems you should start **mysqld** with the `--skip-safemalloc` option. This disables the memory overrun checks for each call to `malloc()` and `free()`.

If **mysqld** stops crashing when you compile it with `--with-debug`, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` to the `CFLAGS` and `CXXFLAGS` variables above and not use `--with-debug`. If **mysqld** dies, you can at least attach to it with **gdb** or use **gdb** on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of **mysqld**. If they find something “unexpected,” an entry is written to `stderr`, which **safe\_mysqld** directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you

should do is to configure MySQL for debugging! (The second thing is to send mail to a MySQL mailing list and ask for help. See Section 1.6.1.1, “The MySQL Mailing Lists”. Please use the **mysqlbug** script for all bug reports or questions regarding the MySQL version you are using!

In the Windows MySQL distribution, `mysqld.exe` is by default compiled with support for trace files.

## E.1.2. Creating Trace Files

If the **mysqld** server doesn't start or if you can cause it to crash quickly, you can try to create a trace file to find the problem.

To do this, you must have a **mysqld** that has been compiled with debugging support. You can check this by executing `mysqld -v`. If the version number ends with `-debug`, it's compiled with support for trace files. (On Windows, the debugging server is named **mysqld-debug** rather than **mysqld** as of MySQL 4.1.)

Start the **mysqld** server with a trace log in `/tmp/mysqld.trace` on Unix or `C:\mysqld.trace` on Windows:

```
shell> mysqld --debug
```

On Windows, you should also use the `--standalone` flag to not start **mysqld** as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the **mysqld** server with **mysqladmin shutdown**.

Note that the trace file become **very big!** If you want to generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:O:/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you make a bug report about this, please only send the lines from the trace file to the appropriate mailing list where something seems to go wrong! If you can't locate the wrong place, you can ftp the trace file, together with a full bug report, to `ftp://ftp.mysql.com/pub/mysql/upload/` so that a MySQL developer can take a look at this.

The trace file is made with the **DEBUG** package by Fred Fish. See Section E.3, “The DEBUG Package”.

## E.1.3. Debugging mysqld under gdb

On most systems you can also start **mysqld** from **gdb** to get more information if **mysqld** crashes.

With some older **gdb** versions on Linux you must use `run --one-thread` if you want to be able to debug **mysqld** threads. In this case, you can only have one thread active at a time. We recommend you to upgrade to **gdb** 5.1 ASAP as thread debugging works much better with this version!

NTPL threads (the new thread library on Linux) may cause problems while running **mysqld** under **gdb**. Some symptoms are:

- **mysqld** hangs during startup (before it writes `ready for connections`).
- **mysqld** crashes during a `pthread_mutex_lock()` or `pthread_mutex_unlock()` call.

In this case you should set the following environment variable in the shell before starting **gdb**:

```
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running **mysqld** under **gdb**, you should disable the stack trace with `-skip-stack-trace` to be able to catch segfaults within **gdb**.

In MySQL 4.0.14 and above you should use the `--gdb` option to **mysqld**. This installs an interrupt handler for SIGINT (needed to stop **mysqld** with ^C to set breakpoints) and disable stack tracing and core file handling.

It's very hard to debug MySQL under **gdb** if you do a lot of new connections the whole time as **gdb** doesn't free the memory for old threads. You can avoid this problem by starting **mysqld** with `-O thread_cache_size= 'max_connections +1'`. In most cases just using `-O thread_cache_size=5` helps a lot!

If you want to get a core dump on Linux if **mysqld** dies with a SIGSEGV signal, you can start **mysqld** with the `--core-file` option. This core file can be used to make a backtrace that may help you find out why **mysqld** died:

```
shell> gdb mysqld core
gdb> backtrace full
gdb> exit
```

See Section A.4.2, “What to Do If MySQL Keeps Crashing”.

If you are using **gdb** 4.17.x or above on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```
set print sevenbit off
handle SIGUSR1 nostop noprint
handle SIGUSR2 nostop noprint
handle SIGWAITING nostop noprint
handle SIGLWP nostop noprint
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGHUP nostop
handle SIGTERM nostop noprint
```

If you have problems debugging threads with **gdb**, you should download **gdb** 5.x and try this instead. The new **gdb** version has very improved thread handling!

Here is an example how to debug **mysqld**:

```
shell> gdb /usr/local/libexec/mysqld
gdb> run
...
backtrace full # Do this when mysqld crashes
```

Include the above output in a mail generated with **mysqlbug** and mail this to the general MySQL mailing list. See Section 1.6.1.1, “The MySQL Mailing Lists”.

If **mysqld** hangs you can try to use some system tools like `strace` or `/usr/proc/bin/pstack` to examine where **mysqld** has hung.

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl DBI interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

## E.1.4. Using a Stack Trace

On some operating systems, the error log contains a stack trace if **mysqld** dies unexpectedly. You can use this to find out where (and maybe why) **mysqld** died. See Section 5.10.1, “The Error Log”. To get a stack trace, you must not compile **mysqld** with the `-fomit-frame-pointer` option to `gcc`. See Section E.1.1, “Compiling MySQL for Debugging”.

If the error file contains something like the following:

```
mysqld got signal 11;
The manual section 'Debugging a MySQL server' tells you how to use a
stack trace and/or the core file to produce a readable backtrace that may
help in finding out why mysqld died
Attempting backtrace. You can use the following information to find out
where mysqld died. If you see no messages after this, something went
terribly wrong...
stack range sanity check, ok, backtrace follows
0x40077552
0x81281a0
0x8128f47
0x8127be0
0x8127995
0x8104947
0x80ff28f
0x810131b
0x80ee4bc
0x80c3c91
0x80c6b43
0x80c1fd9
0x80c1686
```

you can find where **mysqld** died by doing the following:

1. Copy the preceding numbers to a file, for example `mysqld.stack`.
2. Make a symbol file for the **mysqld** server:

```
nm -n libexec/mysqld > /tmp/mysqld.sym
```

Note that most MySQL binary distributions (except for the “debug” packages, where this information is included inside of the binaries themselves) ship with the above file, named `mysqld.sym.gz`. In this case, you can simply unpack it by doing:

```
gunzip < bin/mysqld.sym.gz > /tmp/mysqld.sym
```

3. Execute `resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack`.

This prints out where **mysqld** died. If this doesn't help you find out why **mysqld** died, you should make a bug report and include the output from the above command with the bug report.

Note however that in most cases it does not help us to just have a stack trace to find the reason for the problem. To be able to locate the bug or provide a workaround, we would in most cases need to know the query that killed **mysqld** and preferably a test case so that we can repeat the problem! See Section 1.6.1.3, “How to Report Bugs or Problems”.

## E.1.5. Using Log Files to Find Cause of Errors in **mysqld**

Note that before starting **mysqld** with `--log` you should check all your tables with **myisamchk**. See Chapter 5, *Database Administration*.

If **mysqld** dies or hangs, you should start **mysqld** with `--log`. When **mysqld** dies again, you can examine the end of the log file for the query that killed **mysqld**.

If you are using `--log` without a file name, the log is stored in the database directory as `host_name.log`. In most cases it is the last query in the log file that killed **mysqld**, but if possible you should verify this by restarting **mysqld** and executing the found query from the **mysql** command-line tools. If this works, you should also test all complicated queries that didn't complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that **mysqld** is using indexes properly. See Section 7.2.1, “`EXPLAIN` Syntax (Get Information About a `SELECT`)”.

You can find the queries that take a long time to execute by starting **mysqld** with `--log-slow-queries`. See Section 5.10.5, “The Slow Query Log”.

If you find the text `mysqld restarted` in the error log file (normally named `hostname.err`) you probably have found a query that causes **mysqld** to fail. If this happens, you should check all your tables with **myisamchk** (see Chapter 5, *Database Administration*), and test the queries in the MySQL log files to see if one doesn't work. If you find such a query, try first upgrading to the newest MySQL version. If this doesn't help and you can't find anything in the `mysql` mail archive, you should report the bug to a MySQL mailing list. The mailing lists are described at <http://lists.mysql.com/>, which also has links to online list archives.

If you have started **mysqld** with `myisam-recover`, MySQL automatically checks and tries to repair MyISAM tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file 'Warning: Checking table ...' which is followed by 'Warning: Repairing table' if the table needs to be repaired. If you get a lot of these errors, without **mysqld** having died unexpectedly just before, then something is wrong and needs to be investigated further. See Section 5.3.1, “**mysqld** Command-Line Options”.

It's not a good sign if **mysqld** did die unexpectedly, but in this case one shouldn't investigate the 'Checking table...' messages but instead try to find out why **mysqld** died.

## E.1.6. Making a Test Case If You Experience Table Corruption

If you get corrupted tables or if **mysqld** always fails after some update commands, you can test whether this bug is reproducible by doing the following:

- Take down the MySQL daemon (with **mysqladmin shutdown**).
- Make a backup of the tables (to guard against the very unlikely case that the repair does something bad).
- Check all tables with **myisamchk -s database/\*.MYI**. Repair any wrong tables with **myisamchk -r database/table.MYI**.
- Make a second backup of the tables.
- Remove (or move away) any old log files from the MySQL data directory if you need more space.
- Start **mysqld** with `--log-bin`. See Section 5.10.4, “The Binary Log”. If you want to find a query that crashes **mysqld**, you should use `--log --log-bin`.
- When you have gotten a crashed table, stop the `mysqld` server.
- Restore the backup.
- Restart the **mysqld** server **without** `--log-bin`

- Re-execute the commands with **mysqlbinlog update-log-file | mysql**. The update log is saved in the MySQL database directory with the name `hostname-bin.#`.
- If the tables are corrupted again or you can get **mysqld** to die with the above command, you have found a reproducible bug that should be easy to fix! FTP the tables and the binary log to `ftp://ftp.mysql.com/pub/mysql/upload/` and enter it into our bugs system at `http://bugs.mysql.com/`. If you are a support customer, you can use the MySQL Customer Support Center `https://support.mysql.com/` to alert the MySQL team about the problem and have it fixed as soon as possible.

You can also use the script `mysql_find_rows` to just execute some of the update statements if you want to narrow down the problem.

## E.2. Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `--with-debug` or `--with-debug=full`. See Section 2.8.2, “Typical **configure** Options”.

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```
shell> MYSQL_DEBUG=d:t:0,/tmp/client.trace
shell> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running **mysql** in debugging mode (assuming that you have compiled MySQL with debugging on):

```
shell> mysql --debug=d:t:0,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See Section 1.6.1.3, “How to Report Bugs or Problems”.

If your client crashes at some 'legal' looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

## E.3. The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is debugging. See Section E.1.2, “Creating Trace Files”.

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support. For more information about programming with the DBUG package, see the DBUG manual in the `dbug` directory of MySQL source distributions. It's best to use a recent distribution for MySQL 5.0 to get the most updated DBUG manual.

You use the debug package by invoking a program with the `--debug="..."` or the `-#...` option.

Most MySQL programs have a default debug string that is used if you don't specify an option to `--debug`. The default trace file is usually `/tmp/program_name.trace` on Unix and `\program_name.trace` on Windows.

The debug control string is a sequence of colon-separated fields as follows:

```
<field_1>:<field_2>:...:<field_N>
```

Each field consists of a mandatory flag character followed by an optional ',' and comma-separated list of modifiers:

```
flag[,modifier,modifier,...,modifier]
```

The currently recognized flag characters are:

| Flag | Description                                                                                                                                                                                                                                                                              |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d    | Enable output from <code>DEBUG_&lt;N&gt;</code> macros for the current state. May be followed by a list of keywords which selects output only for the <code>DEBUG</code> macros with that keyword. An empty list of keywords implies output for all macros.                              |
| D    | Delay after each debugger output line. The argument is the number of tenths of seconds to delay, subject to machine capabilities. For example, <code>-#D,20</code> specifies a delay of two seconds.                                                                                     |
| f    | Limit debugging and/or tracing, and profiling to the list of named functions. Note that a null list disables all functions. The appropriate <code>d</code> or <code>t</code> flags must still be given; this flag only limits their actions if they are enabled.                         |
| F    | Identify the source file name for each line of debug or trace output.                                                                                                                                                                                                                    |
| i    | Identify the process with the PID or thread ID for each line of debug or trace output.                                                                                                                                                                                                   |
| g    | Enable profiling. Create a file called <code>debugmon.out</code> containing information that can be used to profile the program. May be followed by a list of keywords that select profiling only for the functions in that list. A null list implies that all functions are considered. |
| L    | Identify the source file line number for each line of debug or trace output.                                                                                                                                                                                                             |
| n    | Print the current function nesting depth for each line of debug or trace output.                                                                                                                                                                                                         |
| N    | Number each line of debug output.                                                                                                                                                                                                                                                        |
| o    | Redirect the debugger output stream to the specified file. The default output is <code>stderr</code> .                                                                                                                                                                                   |
| O    | Like <code>o</code> , but the file is really flushed between each write. When needed, the file is closed and reopened between each write.                                                                                                                                                |
| p    | Limit debugger actions to specified processes. A process must be identified with the <code>DEBUG_PROCESS</code> macro and match one in the list for debugger actions to occur.                                                                                                           |
| P    | Print the current process name for each line of debug or trace output.                                                                                                                                                                                                                   |
| r    | When pushing a new state, do not inherit the previous state's function nesting level. Useful when the output is to start at the left margin.                                                                                                                                             |
| S    | Do function <code>_sanity(_file_,_line_)</code> at each debugged function until <code>_sanity()</code> returns something that differs from 0. (Mostly used with <code>safemalloc</code> to find memory leaks)                                                                            |
| t    | Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.                                        |

Some examples of debug control strings that might appear on a shell command line (the `-#` is typically used to introduce a control string to an application program) are:

```
-#d:t
-#d:f,main,subr1:F:L:t,20
-#d,input,output,files:n
-#d:t:i:0,\\mysqld.trace
```

In MySQL, common tags to print (with the `d` option) are `enter`, `exit`, `error`, `warning`, `info`, and `loop`.

## E.4. Comments about RTS Threads

I have tried to use the RTS thread packages with MySQL but stumbled on the following problems:

They use old versions of many POSIX calls and it is very tedious to make wrappers for all functions. I am inclined to think that it would be easier to change the thread libraries to the newest POSIX specification.

Some wrappers are currently written. See `mysys/my_pthread.c` for more info.

At least the following should be changed:

`pthread_get_specific` should use one argument. `sigwait` should take two arguments. A lot of functions (at least `pthread_cond_wait`, `pthread_cond_timedwait()`) should return the error code on error. Now they return -1 and set `errno`.

Another problem is that user-level threads use the `ALRM` signal and this aborts a lot of functions (`read`, `write`, `open`...). MySQL should do a retry on interrupt on all of these but it is not that easy to verify it.

The biggest unsolved problem is the following:

To get thread-level alarms I changed `mysys/thr_alarm.c` to wait between alarms with `pthread_cond_timedwait()`, but this aborts with error `EINTR`. I tried to debug the thread library as to why this happens, but couldn't find any easy solution.

If someone wants to try MySQL with RTS threads I suggest the following:

- Change functions MySQL uses from the thread library to POSIX. This shouldn't take that long.
- Compile all libraries with the `-DHAVE_rts_threads`.
- Compile `thr_alarm`.
- If there are some small differences in the implementation, they may be fixed by changing `my_pthread.h` and `my_pthread.c`.
- Run `thr_alarm`. If it runs without any ```warning," ``error,"` or aborted messages, you are on the right track. Here is a successful run on Solaris:

```
Main thread: 1
Thread 0 (5) started
Thread: 5 Waiting
process_alarm
Thread 1 (6) started
Thread: 6 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 1 (1) sec
Thread: 6 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 2 (2) sec
Thread: 6 Simulation of no alarm needed
Thread: 6 Slept for 0 (3) sec
Thread: 6 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 4 (4) sec
Thread: 6 Waiting
process_alarm
thread_alarm
```

```
Thread: 5 Slept for 10 (10) sec
Thread: 5 Waiting
process_alarm
process_alarm
thread_alarm
Thread: 6 Slept for 5 (5) sec
Thread: 6 Waiting
process_alarm
process_alarm

...
thread_alarm
Thread: 5 Slept for 0 (1) sec
end
```

## E.5. Differences Between Thread Packages

MySQL is very dependent on the thread package used. So when choosing a good platform for MySQL, the thread package is very important.

There are at least three types of thread packages:

- User threads in a single process. Thread switching is managed with alarms and the threads library manages all non-thread-safe functions with locks. Read, write and select operations are usually managed with a thread-specific select that switches to another thread if the running threads have to wait for data. If the user thread packages are integrated in the standard libs (FreeBSD and BSDI threads) the thread package requires less overhead than thread packages that have to map all unsafe calls (MIT-pthreads, FSU Pthreads and RTS threads). In some environments (for example, SCO), all system calls are thread-safe so the mapping can be done very easily (FSU Pthreads on SCO). Downside: All mapped calls take a little time and it's quite tricky to be able to handle all situations. There are usually also some system calls that are not handled by the thread package (like MIT-pthreads and sockets). Thread scheduling isn't always optimal.
- User threads in separate processes. Thread switching is done by the kernel and all data are shared between threads. The thread package manages the standard thread calls to allow sharing data between threads. LinuxThreads is using this method. Downside: Lots of processes. Thread creating is slow. If one thread dies the rest are usually left hanging and you must kill them all before restarting. Thread switching is somewhat expensive.
- Kernel threads. Thread switching is handled by the thread library or the kernel and is very fast. Everything is done in one process, but on some systems, **ps** may show the different threads. If one thread aborts, the whole process aborts. Most system calls are thread-safe and should require very little overhead. Solaris, HP-UX, AIX and OSF/1 have kernel threads.

In some systems kernel threads are managed by integrating user level threads in the system libraries. In such cases, the thread switching can only be done by the thread library and the kernel isn't really ``thread aware."`

---

# Appendix F. Environment Variables

This appendix lists all the environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Note that any options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables.

In many cases, it's preferable to use an option file instead of environment variables to modify the behavior of MySQL. See Section 4.3.2, "Using Option Files".

| Variable        | Description                                                                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| CXX             | The name of your C++ compiler (for running <b>configure</b> ).                                                                                |
| CC              | The name of your C compiler (for running <b>configure</b> ).                                                                                  |
| CFLAGS          | Flags for your C compiler (for running <b>configure</b> ).                                                                                    |
| CXXFLAGS        | Flags for your C++ compiler (for running <b>configure</b> ).                                                                                  |
| DBI_USER        | The default username for Perl DBI.                                                                                                            |
| DBI_TRACE       | Trace options for Perl DBI.                                                                                                                   |
| HOME            | The default path for the <b>mysql</b> history file is \$HOME/.mysql_history.                                                                  |
| LD_RUN_PATH     | Used to specify where your <code>libmysqlclient.so</code> is located.                                                                         |
| MYSQL_DEBUG     | Debug trace options when debugging.                                                                                                           |
| MYSQL_HISTFILE  | The path to the <b>mysql</b> history file. If this variable is set, its value overrides the default of \$HOME/.mysql_history.                 |
| MYSQL_HOST      | The default hostname used by the <b>mysql</b> command-line client.                                                                            |
| MYSQL_PS1       | The command prompt to use in the <b>mysql</b> command-line client.                                                                            |
| MYSQL_PWD       | The default password when connecting to <b>mysqld</b> . Note that use of this is insecure! See Section 5.7.6, "Keeping Your Password Secure". |
| MYSQL_TCP_PORT  | The default TCP/IP port number.                                                                                                               |
| MYSQL_UNIX_PORT | The default Unix socket filename; used for connections to <code>localhost</code> .                                                            |
| PATH            | Used by the shell to find MySQL programs.                                                                                                     |
| TMPDIR          | The directory where temporary files are created.                                                                                              |
| TZ              | This should be set to your local time zone. See Section A.4.6, "Time Zone Problems".                                                          |
| UMASK_DIR       | The user-directory creation mask when creating directories. Note that this is ANDed with <b>UMASK</b> !                                       |
| UMASK           | The user-file creation mask when creating files.                                                                                              |
| USER            | The default username on Windows and NetWare to use when connecting to <b>mysqld</b> .                                                         |

---

# Appendix G. MySQL Regular Expressions

A regular expression is a powerful way of specifying a pattern for a complex search.

MySQL uses Henry Spencer's implementation of regular expressions, which is aimed at conformance with POSIX 1003.2. See Appendix B, *Credits*. MySQL uses the extended version to support pattern-matching operations performed with the REGEXP operator in SQL statements. See Section 3.3.4.7, "Pattern Matching".

This appendix is a summary, with examples, of the special characters and constructs that can be used in MySQL for REGEXP operations. It does not contain all the details that can be found in Henry Spencer's `regex(7)` manual page. That manual page is included in MySQL source distributions, in the `regex.7` file under the `regex` directory.

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Non-trivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|word` matches either the string `hello` or the string `word`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Banas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of a or `n` characters in between.

A regular expression for the REGEXP operator may use any of the following special characters and constructs:

- `^`

Match the beginning of a string.

```
mysql> SELECT 'fo\nfo' REGEXP '^fo$'; -> 0
mysql> SELECT 'fofo' REGEXP '^fo'; -> 1
```

- `$`

Match the end of a string.

```
mysql> SELECT 'fo\no' REGEXP '^fo\no$'; -> 1
mysql> SELECT 'fo\no' REGEXP '^fo$'; -> 0
```

- `.`

Match any character (including carriage return and newline).

```
mysql> SELECT 'fofo' REGEXP '^f.*$'; -> 1
mysql> SELECT 'fo\r\nfo' REGEXP '^f.*$'; -> 1
```

- `a*`

Match any sequence of zero or more `a` characters.

```
mysql> SELECT 'Ban' REGEXP '^Ba*n'; -> 1
mysql> SELECT 'Baaan' REGEXP '^Ba*n'; -> 1
mysql> SELECT 'Bn' REGEXP '^Ba*n'; -> 1
```

- a+

Match any sequence of one or more a characters.

```
mysql> SELECT 'Ban' REGEXP '^Ba+n'; -> 1
mysql> SELECT 'Bn' REGEXP '^Ba+n'; -> 0
```

- a?

Match either zero or one a character.

```
mysql> SELECT 'Bn' REGEXP '^Ba?n'; -> 1
mysql> SELECT 'Ban' REGEXP '^Ba?n'; -> 1
mysql> SELECT 'Baan' REGEXP '^Ba?n'; -> 0
```

- de|abc

Match either of the sequences de or abc.

```
mysql> SELECT 'pi' REGEXP 'pi|apa'; -> 1
mysql> SELECT 'axe' REGEXP 'pi|apa'; -> 0
mysql> SELECT 'apa' REGEXP 'pi|apa'; -> 1
mysql> SELECT 'apa' REGEXP '^ (pi|apa) $'; -> 1
mysql> SELECT 'pi' REGEXP '^ (pi|apa) $'; -> 1
mysql> SELECT 'pix' REGEXP '^ (pi|apa) $'; -> 0
```

- (abc)\*

Match zero or more instances of the sequence abc.

```
mysql> SELECT 'pi' REGEXP '^ (pi) * $'; -> 1
mysql> SELECT 'pip' REGEXP '^ (pi) * $'; -> 0
mysql> SELECT 'pipi' REGEXP '^ (pi) * $'; -> 1
```

- {1}, {2, 3}

{n} or {m, n} notation provides a more general way of writing regular expressions that match many occurrences of the previous atom (or "piece") of the pattern. m and n are integers.

- a\*

Can be written as a{0, }.

- a+

Can be written as a{1, }.

- a?

Can be written as a{0, 1}.

To be more precise, a{n} matches exactly n instances of a. a{n, } matches n or more instances of a. a{m, n} matches m through n instances of a, inclusive.

m and n must be in the range from 0 to RE\_DUP\_MAX (default 255), inclusive. If both m and n are given, m must be less than or equal to n.

```
mysql> SELECT 'abcde' REGEXP 'a[bcd]{2}e'; -> 0
```

```
mysql> SELECT 'abcde' REGEXP 'a[bcd]{3}e'; -> 1
mysql> SELECT 'abcde' REGEXP 'a[bcd]{1,10}e'; -> 1
```

- [a-dX], [^a-dX]

Matches any character that is (or is not, if ^ is used) either a, b, c, d or X. A - character between two other characters forms a range that matches all characters from the first character to the second. For example, [0-9] matches any decimal digit. To include a literal ] character, it must immediately follow the opening bracket [. To include a literal - character, it must be written first or last. Any character that does not have a defined special meaning inside a [] pair matches only itself.

```
mysql> SELECT 'aXbc' REGEXP '[a-dXYZ]'; -> 1
mysql> SELECT 'aXbc' REGEXP '^[a-dXYZ]$'; -> 0
mysql> SELECT 'aXbc' REGEXP '[a-dXYZ]+$'; -> 1
mysql> SELECT 'aXbc' REGEXP '^[^a-dXYZ]+$'; -> 0
mysql> SELECT 'gheis' REGEXP '^[^a-dXYZ]+$'; -> 1
mysql> SELECT 'gheisa' REGEXP '^[^a-dXYZ]+$'; -> 0
```

- [.characters.]

Within a bracket expression (written using [ and ]), matches the sequence of characters of that collating element. characters is either a single character or a character name like newline. You can find the full list of character names in the regexp/cname.h file.

```
mysql> SELECT '~' REGEXP '[[.~.]]'; -> 1
mysql> SELECT '~' REGEXP '[[.tilde.]]'; -> 1
```

- [=character\_class=]

Within a bracket expression (written using [ and ]), [=character\_class=] represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if o and (+) are the members of an equivalence class, then [[=o=]], [[=(+)=]], and [o(+)] are all synonymous. An equivalence class may not be used as an endpoint of a range.

- [:character\_class:]

Within a bracket expression (written using [ and ]), [:character\_class:] represents a character class that matches all characters belonging to that class. The standard class names are:

|            |                                 |
|------------|---------------------------------|
| al-<br>num | Alphanumeric characters         |
| al-<br>pha | Alphabetic characters           |
| bla<br>nk  | Whitespace characters           |
| cnt<br>rl  | Control characters              |
| di-<br>git | Digit characters                |
| gra<br>ph  | Graphic characters              |
| low<br>er  | Lowercase alphabetic characters |
| pri        | Graphic or space characters     |

|        |                                          |
|--------|------------------------------------------|
| nt     |                                          |
| punct  | Punctuation characters                   |
| space  | Space, tab, newline, and carriage return |
| upper  | Uppercase alphabetic characters          |
| xdigit | Hexadecimal digit characters             |

These stand for the character classes defined in the `ctype(3)` manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

```
mysql> SELECT 'justalnums' REGEXP '[:alnum:]+'; -> 1
mysql> SELECT '!!' REGEXP '[:alnum:]+'; -> 0
```

- `[:<:]`, `[:>:]`

These markers stand for word boundaries. They match the beginning and end of words, respectively. A word is a sequence of word characters that is not preceded by or followed by word characters. A word character is an alphanumeric character in the `alnum` class or an underscore (`_`).

```
mysql> SELECT 'a word a' REGEXP '[:<:]word[:>:]'; -> 1
mysql> SELECT 'a xword a' REGEXP '[:<:]word[:>:]'; -> 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (`\`) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```
mysql> SELECT '1+2' REGEXP '1+2'; -> 0
mysql> SELECT '1+2' REGEXP '1\+2'; -> 0
mysql> SELECT '1+2' REGEXP '1\\+2'; -> 1
```

---

# Appendix H. GNU General Public License

Version 2, June 1991

Copyright © 1989, 1991 Free Software Foundation, Inc.  
59 Temple Place - Suite 330, Boston, MA 02111-1307, USA  
Everyone is permitted to copy and distribute verbatim copies  
of this license document, but changing it is not allowed.

## Preamble

The licenses for most software are designed to take away your freedom to share and change it. By contrast, the GNU General Public License is intended to guarantee your freedom to share and change free software---to make sure the software is free for all its users. This General Public License applies to most of the Free Software Foundation's software and to any other program whose authors commit to using it. (Some other Free Software Foundation software is covered by the GNU Library General Public License instead.) You can apply it to your programs, too.

When we speak of free software, we are referring to freedom, not price. Our General Public Licenses are designed to make sure that you have the freedom to distribute copies of free software (and charge for this service if you wish), that you receive source code or can get it if you want it, that you can change the software or use pieces of it in new free programs; and that you know you can do these things.

To protect your rights, we need to make restrictions that forbid anyone to deny you these rights or to ask you to surrender the rights. These restrictions translate to certain responsibilities for you if you distribute copies of the software, or if you modify it.

For example, if you distribute copies of such a program, whether gratis or for a fee, you must give the recipients all the rights that you have. You must make sure that they, too, receive or can get the source code. And you must show them these terms so they know their rights.

We protect your rights with two steps: (1) copyright the software, and (2) offer you this license which gives you legal permission to copy, distribute and/or modify the software.

Also, for each author's protection and ours, we want to make certain that everyone understands that there is no warranty for this free software. If the software is modified by someone else and passed on, we want its recipients to know that what they have is not the original, so that any problems introduced by others will not reflect on the original authors' reputations.

Finally, any free program is threatened constantly by software patents. We wish to avoid the danger that redistributors of a free program will individually obtain patent licenses, in effect making the program proprietary. To prevent this, we have made it clear that any patent must be licensed for everyone's free use or not licensed at all.

The precise terms and conditions for copying, distribution and modification follow.

## GNU GENERAL PUBLIC LICENSE TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

1. This License applies to any program or other work which contains a notice placed by the copyright holder saying it may be distributed under the terms of this General Public License. The ``Program'', below, refers to any such program or work, and a ``work based on the Program'' means either the Program or any derivative work under copyright law: that is to say, a work containing the Program or a portion of it, either verbatim or with modifications and/or trans-

lated into another language. (Hereinafter, translation is included without limitation in the term ``modification".) Each licensee is addressed as ``you".

Activities other than copying, distribution and modification are not covered by this License; they are outside its scope. The act of running the Program is not restricted, and the output from the Program is covered only if its contents constitute a work based on the Program (independent of having been made by running the Program). Whether that is true depends on what the Program does.

2. You may copy and distribute verbatim copies of the Program's source code as you receive it, in any medium, provided that you conspicuously and appropriately publish on each copy an appropriate copyright notice and disclaimer of warranty; keep intact all the notices that refer to this License and to the absence of any warranty; and give any other recipients of the Program a copy of this License along with the Program.

You may charge a fee for the physical act of transferring a copy, and you may at your option offer warranty protection in exchange for a fee.

3. You may modify your copy or copies of the Program or any portion of it, thus forming a work based on the Program, and copy and distribute such modifications or work under the terms of Section 1 above, provided that you also meet all of these conditions:
  - a. You must cause the modified files to carry prominent notices stating that you changed the files and the date of any change.
  - b. You must cause any work that you distribute or publish, that in whole or in part contains or is derived from the Program or any part thereof, to be licensed as a whole at no charge to all third parties under the terms of this License.
  - c. If the modified program normally reads commands interactively when run, you must cause it, when started running for such interactive use in the most ordinary way, to print or display an announcement including an appropriate copyright notice and a notice that there is no warranty (or else, saying that you provide a warranty) and that users may redistribute the program under these conditions, and telling the user how to view a copy of this License. (Exception: if the Program itself is interactive but does not normally print such an announcement, your work based on the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole. If identifiable sections of that work are not derived from the Program, and can be reasonably considered independent and separate works in themselves, then this License, and its terms, do not apply to those sections when you distribute them as separate works. But when you distribute the same sections as part of a whole which is a work based on the Program, the distribution of the whole must be on the terms of this License, whose permissions for other licensees extend to the entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest your rights to work written entirely by you; rather, the intent is to exercise the right to control the distribution of derivative or collective works based on the Program.

In addition, mere aggregation of another work not based on the Program with the Program (or with a work based on the Program) on a volume of a storage or distribution medium does not bring the other work under the scope of this License.

4. You may copy and distribute the Program (or a work based on it, under Section 2) in object code or executable form under the terms of Sections 1 and 2 above provided that you also do one of the following:
  - a. Accompany it with the complete corresponding machine-readable source code, which must be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,
  - b. Accompany it with a written offer, valid for at least three years, to give any third-party,

for a charge no more than your cost of physically performing source distribution, a complete machine-readable copy of the corresponding source code, to be distributed under the terms of Sections 1 and 2 above on a medium customarily used for software interchange; or,

- c. Accompany it with the information you received as to the offer to distribute corresponding source code. (This alternative is allowed only for noncommercial distribution and only if you received the program in object code or executable form with such an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for making modifications to it. For an executable work, complete source code means all the source code for all modules it contains, plus any associated interface definition files, plus the scripts used to control compilation and installation of the executable. However, as a special exception, the source code distributed need not include anything that is normally distributed (in either source or binary form) with the major components (compiler, kernel, and so on) of the operating system on which the executable runs, unless that component itself accompanies the executable.

If distribution of executable or object code is made by offering access to copy from a designated place, then offering equivalent access to copy the source code from the same place counts as distribution of the source code, even though third parties are not compelled to copy the source along with the object code.

5. You may not copy, modify, sublicense, or distribute the Program except as expressly provided under this License. Any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License. However, parties who have received copies, or rights, from you under this License will not have their licenses terminated so long as such parties remain in full compliance.
6. You are not required to accept this License, since you have not signed it. However, nothing else grants you permission to modify or distribute the Program or its derivative works. These actions are prohibited by law if you do not accept this License. Therefore, by modifying or distributing the Program (or any work based on the Program), you indicate your acceptance of this License to do so, and all its terms and conditions for copying, distributing or modifying the Program or works based on it.
7. Each time you redistribute the Program (or any work based on the Program), the recipient automatically receives a license from the original licensor to copy, distribute or modify the Program subject to these terms and conditions. You may not impose any further restrictions on the recipients' exercise of the rights granted herein. You are not responsible for enforcing compliance by third parties to this License.
8. If, as a consequence of a court judgment or allegation of patent infringement or for any other reason (not limited to patent issues), conditions are imposed on you (whether by court order, agreement or otherwise) that contradict the conditions of this License, they do not excuse you from the conditions of this License. If you cannot distribute so as to satisfy simultaneously your obligations under this License and any other pertinent obligations, then as a consequence you may not distribute the Program at all. For example, if a patent license would not permit royalty-free redistribution of the Program by all those who receive copies directly or indirectly through you, then the only way you could satisfy both it and this License would be to refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under any particular circumstance, the balance of the section is intended to apply and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any patents or other property right claims or to contest validity of any such claims; this section has the sole purpose of protecting the integrity of the free software distribution system, which is implemented by public license practices. Many people have made generous contributions to the wide range of software distributed through that system in reliance on consistent application of that system; it is up to the author/donor to decide if he or she is willing to distribute software through any other system and

a licensee cannot impose that choice.

This section is intended to make thoroughly clear what is believed to be a consequence of the rest of this License.

9. If the distribution and/or use of the Program is restricted in certain countries either by patents or by copyrighted interfaces, the original copyright holder who places the Program under this License may add an explicit geographical distribution limitation excluding those countries, so that distribution is permitted only in or among countries not thus excluded. In such case, this License incorporates the limitation as if written in the body of this License.
10. The Free Software Foundation may publish revised and/or new versions of the General Public License from time to time. Such new versions will be similar in spirit to the present version, but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number. If the Program specifies a version number of this License which applies to it and ``any later version'', you have the option of following the terms and conditions either of that version or of any later version published by the Free Software Foundation. If the Program does not specify a version number of this License, you may choose any version ever published by the Free Software Foundation.

11. If you wish to incorporate parts of the Program into other free programs whose distribution conditions are different, write to the author to ask for permission. For software which is copyrighted by the Free Software Foundation, write to the Free Software Foundation; we sometimes make exceptions for this. Our decision will be guided by the two goals of preserving the free status of all derivatives of our free software and of promoting the sharing and reuse of software generally.

#### NO WARRANTY

12. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW. EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES PROVIDE THE PROGRAM ``AS IS'' WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE. THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU. SHOULD THE PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.
13. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

#### END OF TERMS AND CONDITIONS

#### **How to Apply These Terms to Your New Programs**

If you develop a new program, and you want it to be of the greatest possible use to the public, the best way to achieve this is to make it free software which everyone can redistribute and change under these terms.

To do so, attach the following notices to the program. It is safest to attach them to the start of each

source file to most effectively convey the exclusion of warranty; and each file should have at least the ``copyright" line and a pointer to where the full notice is found.

*one line to give the program's name and a brief idea of what it does.*  
Copyright (C) yyyy name of author

This program is free software; you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; either version 2 of the License, or (at your option) any later version.

This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU General Public License for more details.

You should have received a copy of the GNU General Public License along with this program; if not, write to the Free Software Foundation, Inc., 59 Temple Place - Suite 330, Boston, MA 02111-1307, USA.

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this when it starts in an interactive mode:

```
Gnomovision version 69, Copyright (C) 19yy name of author
Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type `show w'.
This is free software, and you are welcome to redistribute it
under certain conditions; type `show c' for details.
```

The hypothetical commands 'show w' and 'show c' should show the appropriate parts of the General Public License. Of course, the commands you use may be called something other than 'show w' and 'show c'; they could even be mouse-clicks or menu items---whatever suits your program.

You should also get your employer (if you work as a programmer) or your school, if any, to sign a ``copyright disclaimer" for the program, if necessary. Here is a sample; alter the names:

```
Yoyodyne, Inc., hereby disclaims all copyright interest in the program
`Gnomovision' (which makes passes at compilers) written by James Hacker.
```

```
signature of Ty Coon, 1 April 1989
Ty Coon, President of Vice
```

This General Public License does not permit incorporating your program into proprietary programs. If your program is a subroutine library, you may consider it more useful to permit linking proprietary applications with the library. If this is what you want to do, use the GNU Library General Public License instead of this License.

---

# Appendix I. MySQL FLOSS License Exception

Version 0.3, 10 February 2005

The MySQL AB Exception for Free/Libre and Open Source Software-only Applications Using MySQL Client Libraries (the "FLOSS Exception").

## Exception Intent

We want specified Free/Libre and Open Source Software ("FLOSS") applications to be able to use specified GPL-licensed MySQL client libraries (the "Program") despite the fact that not all FLOSS licenses are compatible with version 2 of the GNU General Public License (the "GPL").

## Legal Terms and Conditions

As a special exception to the terms and conditions of version 2.0 of the GPL:

1. You are free to distribute a Derivative Work that is formed entirely from the Program and one or more works (each, a "FLOSS Work") licensed under one or more of the licenses listed below in section 1, as long as:
  - a. You obey the GPL in all respects for the Program and the Derivative Work, except for identifiable sections of the Derivative Work which are not derived from the Program, and which can reasonably be considered independent and separate works in themselves,
  - b. all identifiable sections of the Derivative Work which are not derived from the Program, and which can reasonably be considered independent and separate works in themselves,
    - i  
are distributed subject to one of the FLOSS licenses listed below, and
    - ii  
the object code or executable form of those sections are accompanied by the complete corresponding machine-readable source code for those sections on the same medium and under the same FLOSS license as the corresponding object code or executable forms of those sections, and
  - c. any works which are aggregated with the Program or with a Derivative Work on a volume of a storage or distribution medium in accordance with the GPL, can reasonably be considered independent and separate works in themselves which are not derivatives of either the Program, a Derivative Work or a FLOSS Work.

If the above conditions are not met, then the Program may only be copied, modified, distributed or used under the terms and conditions of the GPL or another valid licensing option from MySQL AB.

## 2. FLOSS License List

| License name                | Version(s)/Copyright Date |
|-----------------------------|---------------------------|
| Academic Free License       | 2.0                       |
| Apache Software License     | 1.0/1.1/2.0               |
| Apple Public Source License | 2.0                       |
| Artistic license            | From Perl 5.8.0           |
| BSD license                 | "July 22 1999"            |

|                                                       |                 |
|-------------------------------------------------------|-----------------|
| Common Public License                                 | 1.0             |
| GNU Library or "Lesser" General Public License (LGPL) | 2.0/2.1         |
| Jabber Open Source License                            | 1.0             |
| MIT license                                           | -               |
| Mozilla Public License (MPL)                          | 1.0/1.1         |
| Open Software License                                 | 2.0             |
| OpenSSL license (with original SSLeay license)        | "2003" ("1998") |
| PHP License                                           | 3.0             |
| Python license (CNRI Python License)                  | -               |
| Python Software Foundation License                    | 2.1.1           |
| Sleepycat License                                     | "1999"          |
| W3C License                                           | "2001"          |
| X11 License                                           | "2001"          |
| Zlib/libpng License                                   | -               |
| Zope Public License                                   | 2.0             |

Due to the many variants of some of the above licenses, we require that any version follow the 2003 version of the Free Software Foundation's Free Software Definition (<http://www.gnu.org/philosophy/free-sw.html>) or version 1.9 of the Open Source Definition by the Open Source Initiative (<http://www.opensource.org/docs/definition.php>).

3. Definitions

- a. Terms used, but not defined, herein shall have the meaning provided in the GPL.
- b. Derivative Work means a derivative work under copyright law.

4. Applicability This FLOSS Exception applies to all Programs that contain a notice placed by MySQL AB saying that the Program may be distributed under the terms of this FLOSS Exception. If you create or distribute a work which is a Derivative Work of both the Program and any other work licensed under the GPL, then this FLOSS Exception is not available for that work; thus, you must remove the FLOSS Exception notice from that work and comply with the GPL in all respects, including by retaining all GPL notices. You may choose to redistribute a copy of the Program exclusively under the terms of the GPL by removing the FLOSS Exception notice from that copy of the Program, provided that the copy has never been modified by you or any third party.
