A Definite Integration Interface for REDUCE

Kerry Gaskell Konrad–Zuse–Zentrum für Informationstechnik Berlin Takustraše 7 D–14195 Berlin – Dahlem Federal Republic of Germany E–mail: neun@zib.de*

July 1994

1 Introduction

This documentation describes part of REDUCE's definite integration package that is able to calculate the definite integrals of many functions, including several special functions. There are other parts of this package, such as Stan Kameny's code for contour integration, that are not included here. The integration process described here is not the more normal approach of initially calculating the indefinite integral, but is instead the rather unusual idea of representing each function as a Meijer G-function (a formal definition of the Meijer G-function can be found in [1]), and then calculating the integral by using the following Meijer G integration formula.

$$\int_{0}^{\infty} x^{\alpha-1} G_{uv}^{st} \left(\sigma x \mid \begin{pmatrix} c_u \\ d_v \end{pmatrix} \right) G_{pq}^{mn} \left(\omega x^{l/k} \mid \begin{pmatrix} a_p \\ b_q \end{pmatrix} \right) dx = k G_{kl}^{ij} \left(\xi \mid \begin{pmatrix} g_k \\ h_l \end{pmatrix} \right)$$
(1)

The resulting Meijer G-function is then retransformed, either directly or via a hypergeometric function simplification, to give the answer. A more detailed account of this theory can be found in [2].

¹This definite integration interface was written during my one year placement at ZIB. Any comments and/or problems should therefore be directed to Winfried Neun at neun@zib.de.

2 Integration between zero and infinity

As an example, if one wishes to calculate the following integral

$$\int_0^\infty x^{-1} e^{-x} \sin(x) \, dx$$

then initially the correct Meijer G-functions are found, via a pattern matching process, and are substituted into (1) to give

$$\sqrt{\pi} \int_0^\infty x^{-1} G_{01}^{10} \left(x \mid \frac{\cdot}{0} \right) G_{02}^{10} \left(\frac{x^2}{4} \mid \frac{\cdot}{\frac{1}{2}} \right) dx$$

The cases for validity of the integral are then checked. If these are found to be satisfactory then the formula is calculated and we obtain the following Meijer G-function

$$G_{22}^{12}\left(1 \left|\begin{array}{c} \frac{1}{2} \\ \frac{1}{2} \end{array}\right)\right)$$

This is reduced to the following hypergeometric function

$$_{2}F_{1}(\frac{1}{2},1;\frac{3}{2};-1)$$

which is then calculated to give the correct answer of

 $\frac{\pi}{4}$

The above formula (1) is also true for the integration of a single Meijer G-function by replacing the second Meijer G-function with a trivial Meijer G-function.

A list of numerous particular Meijer G-functions is available in [1].

3 Integration over other ranges

Although the description so far has been limited to the computation of definite integrals between 0 and infinity, it can also be extended to calculate

integrals between 0 and some specific upper bound, and by further extension, integrals between any two bounds. One approach is to use the Heaviside function, i.e.

$$\int_0^\infty x^2 e^{-x} H(1-x) \, dx = \int_0^1 x^2 e^{-x} dx$$

Another approach, again not involving the normal indefinite integration process, again uses Meijer G-functions, this time by means of the following formula

$$\int_{0}^{y} x^{\alpha - 1} G_{pq}^{mn} \left(\sigma x \mid \begin{pmatrix} a_{u} \\ b_{v} \end{pmatrix} \right) dx = y^{\alpha} G_{p+1\,q+1}^{m\,n+1} \left(\sigma y \mid \begin{pmatrix} a_{1}..a_{n}, 1 - \alpha, a_{n+1}..a_{p} \\ (b_{1}..b_{m}, -\alpha, b_{m+1}..b_{q}) \end{pmatrix} (2)$$

For a more detailed look at the theory behind this see [2].

For example, if one wishes to calculate the following integral

$$\int_0^y \sin(2\sqrt{x}) \, dx$$

then initially the correct Meijer G-function is found, by a pattern matching process, and is substituted into (2) to give

$$\int_0^y G_{02}^{10} \left(x \left| \begin{array}{c} \cdot \cdot \\ \frac{1}{2} \end{array} \right) dx \right.$$

which then in turn gives

$$y G_{13}^{11} \left(y \mid \begin{array}{c} 0 \\ \frac{1}{2} - 1 \end{array} \right) dx$$

and returns the result

$$\frac{\sqrt{\pi}\,J_{3/2}(2\,\sqrt{y})\,y}{y^{1/4}}$$

4 Using the definite integration package

To use this package, you must first load it by the command

load_package defint;

Definite integration is then possible using the int command with the syntax:

where LOW and UP are the lower and upper bounds respectively for the definite integration of EXPRN with respect to VAR.

4.1 Examples

$$\int_0^\infty e^{-x} dx$$

int(e^(-x),x,0,infinity);

1

$$\int_0^\infty x \sin(1/x) \, dx$$

int(x*sin(1/x),x,0,infinity);

$$\int_0^\infty x^2 \cos(x) \, e^{-2x} dx$$

 $int(x^2*cos(x)*e^{(-2*x)},x,0,infinity);$

125

$$\int_0^\infty x e^{-1/2x} H(1-x) \, dx = \int_0^1 x e^{-1/2x} dx$$

```
int(x*e^{(-1/2x)}*Heaviside(1-x),x,0,infinity);
```

```
2*(2*SQRT(E) - 3)
```

SQRT(E)

$$\int_0^1 x \log(1+x) \, dx$$

int(x*log(1+x),x,0,1);

1 ----4

$$\int_0^y \cos(2x) \, dx$$

int(cos(2x),x,y,2y);
SIN(4*Y) - SIN(2*Y)

2

5 Integral Transforms

A useful application of the definite integration package is in the calculation of various integral transforms. The transforms available are as follows:

- Laplace transform
- $\bullet\,$ Hankel transform
- Y-transform
- $\bullet~{\rm K}\text{-}{\rm transform}$
- StruveH transform
- Fourier sine transform
- Fourier cosine transform

5 INTEGRAL TRANSFORMS

5.1 Laplace transform

The Laplace transform

$$f(s) = \mathcal{L} \{ F(t) \} = \int_0^\infty e^{-st} F(t) dt$$

can be calculated by using the laplace_transform command.

This requires as parameters

- the function to be integrated
- the integration variable.

For example

$$\mathcal{L}\left\{e^{-at}\right\}$$

is entered as

laplace_transform(e^(-a*x),x);

and returns the result

$$\frac{1}{s+a}$$

5.2 Hankel transform

The Hankel transform

$$f(\omega) = \int_0^\infty F(t) J_\nu(2\sqrt{\omega t}) dt$$

can be calculated by using the hankel_transform command e.g.

hankel_transform(f(x),x);

This is used in the same way as the laplace_transform command.

5.3 Y-transform

The Y-transform

$$f(\omega) = \int_0^\infty F(t) Y_\nu(2\sqrt{\omega t}) dt$$

can be calculated by using the Y_transform command e.g.

Y_transform(f(x),x);

This is used in the same way as the laplace_transform command.

5.4 K-transform

The K-transform

$$f(\omega) = \int_0^\infty F(t) K_\nu(2\sqrt{\omega t}) dt$$

can be calculated by using the K_transform command e.g.

 $K_transform(f(x),x);$

This is used in the same way as the laplace_transform command.

5.5 StruveH transform

The StruveH transform

$$f(\omega) = \int_0^\infty F(t) StruveH(\nu, 2\sqrt{\omega t}) dt$$

can be calculated by using the struveh_transform command e.g.

```
struveh_transform(f(x),x);
```

This is used in the same way as the laplace_transform command.

5.6 Fourier sine transform

The Fourier sine transform

$$f(s) = \int_0^\infty F(t)\sin(st)\,dt$$

can be calculated by using the fourier_sin command e.g.

fourier_sin(f(x),x);

This is used in the same way as the laplace_transform command.

5.7 Fourier cosine transform

The Fourier cosine transform

$$f(s) = \int_0^\infty F(t) \cos(st) \, dt$$

can be calculated by using the fourier_cos command e.g.

fourier_cos(f(x),x);

This is used in the same way as the laplace_transform command.

6 Additional Meijer G-function Definitions

The relevant Meijer G representation for any function is found by a patternmatching process which is carried out on a list of Meijer G-function definitions. This list, although extensive, can never hope to be complete and therefore the user may wish to add more definitions. Definitions can be added by adding the following lines:

where f(x) is the new function, i = 1..p, j=1..q, C = a constant, var = variable, n = an indexing number.

For example when considering cos(x) we have

Meijer G representation -

$$\sqrt{\pi} G_{02}^{10} \left(\frac{x^2}{4} \mid \frac{\cdot}{0 \frac{1}{2}} \right) dx$$

Internal definite integration package representation -

defint_choose(cos(~x), var) => f1(3,x);

where 3 is the indexing number corresponding to the 3 in the following formula

or the more interesting example of $J_n(x)$:

Meijer G representation -

$$G_{02}^{10}\left(\frac{x^2}{4} \mid \frac{\dots}{\frac{n}{2} - \frac{-n}{2}}\right) dx$$

Internal definite integration package representation -

defint_choose(besselj(~n,~x),~var) => f1(50,x,n);

7 The print_conditions function

The required conditions for the validity of the transform integrals can be viewed using the following command:

print_conditions().

For example after calculating the following laplace transform

laplace_transform(x^k,x);

using the print_conditions command would produce

```
repart(sum(ai) - sum(bj)) + 1/2 (q + 1 - p)>(q - p) repart(s)
and ( - min(repart(bj))<repart(s))<1 - max(repart(ai))
or mod(arg(eta))=pi*delta
or ( - min(repart(bj))<repart(s))<1 - max(repart(ai))</pre>
```

or mod(arg(eta))<pi*delta</pre>

where

$$delta = s + t - \frac{u - v}{2}$$

$$eta = 1 - \alpha(v - u) - \mu - \rho$$

$$\mu = \sum_{j=1}^{q} b_j - \sum_{i=1}^{p} a_i + \frac{p - q}{2} + 1$$

$$\rho = \sum_{j=1}^{v} dj - \sum_{i=1}^{u} c_i + \frac{u - v}{2} + 1$$

$$s, t, u, v, p, q, \alpha \text{ as in } (1)$$

8 Acknowledgements

I would like to thank Victor Adamchik whose implementation of the definite integration package for REDUCEis vital to this interface.
